( $N \times 6.25$ ) 1.3%, reducing sugars as dextrose 2.8%, sucrose 0.2%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 3.9 and  $pH$  4.9.

**Calories.**—0.21 per gram; 6 per ounce.

**Vitamins.**—The equipment and method of manufacture is such as to make possible the retention to a high degree of the vitamin content.

**Claims of Manufacturer.**—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C; for infant feeding and general table use.

(B) BAKER'S MAL-DEX PLAIN

(A) BAKER'S MAL-DEX WITH 2%  
SODIUM CHLORIDE

(C) BAKER'S MAL-DEX WITH 3%  
POTASSIUM BICARBONATE

**Manufacturer.**—The Baker Laboratories, Cleveland.

**Description.**—(B) Essentially a mixture of maltose and dextrans.

(A) Essentially a mixture of maltose and dextrans with 2 per cent sodium chloride added.

(C) Essentially a mixture of maltose and dextrans with 3 per cent potassium bicarbonate added.

**Manufacture.**—(B) The starch base is prepared from starch cereal from which the hulls and hearts have been removed. High diastatic malt (1 pound to each 100 pounds of cereal base) is added to the starch base, and the conversion extended until a definite ratio of maltose to dextrans is obtained (53% maltose to 44% dextrans), after which the liquid is filtered from the residue. The filtrate is decolorized, dehydrated and packed in tins.

(A) Essentially the same as (B) with 2 per cent sodium chloride added before the drying process.

(C) Essentially the same as (B) with 3 per cent potassium bicarbonate added after the dextrin and maltose mixture has been reduced to powder form.

**Analyses** (submitted by manufacturer).—(B) Moisture 3.0%, total solids 97.0%, ash 1.0%, protein ( $N \times 6.25$ ) 0.3-0.5%, maltose 52.5%, dextrin 43.5%, carbohydrates (by difference) 95.7%.

(A) Moisture 3.0%, total solids 97.0%, ash 1.0%, protein ( $N \times 6.25$ ) 0.3-0.5%, sodium chloride 2.0%, maltose 51.5%, dextrin 42.5%, carbohydrates (by difference) 95.7%.

(C) Moisture 3.0%, total solids 97.0%, ash 1.0%, protein ( $N \times 6.25$ ) 0.3-0.5%, maltose, 51.0%, dextrine 42.0%, potassium bicarbonate 3.0% and carbohydrates (by difference) 95.7%.

**Calories.**—3.84 per gram; 109 per ounce.

**Claims of Manufacturer.**—Carbohydrate supplements for the general diet of infants and invalids.

### BISQUICK WITH WHOLE WHEAT

**Manufacturer.**—Gold Medal Foods, Incorporated, a wholly owned subsidiary of General Mills, Inc., Minneapolis.

**Description.**—A self-rising white and whole wheat flour containing vegetable shortening, acid phosphates, sucrose, skim milk powder, salt and baking soda; especially prepared for biscuits.

**Manufacture.**—The nonfat ingredients are thoroughly mixed in a batch-mixer; the shortening is added and all are again thoroughly mixed.

**Analysis** (submitted by manufacturer).—Moisture 9.5-10%, total solids 90.5-90%, ash 7.0-7.3%, fat (ether extract) 13.0-13.7%, protein ( $N \times 5.7$ ) 8.5-10.5%, crude fiber 1.3-1.4%, sucrose 3.2-3.4% and carbohydrates other than crude fiber (by difference) 60.7-57.1%.

**Calories.**—3.94 per gram; 112 per ounce.

**Claims of Manufacturer.**—A self-rising flour containing shortening already worked in and requiring only admixture with water or milk for the preparation of biscuits; the baked product has a whole wheat flavor.

subscribers to the said plan under a contract which entitles each subscriber to certain hospital care in the event of sickness. H. 129 proposes that coroners be duly qualified licensed physicians.

### KANSAS

**Course on Neuropsychiatry.**—The third annual graduate course on neuropsychiatry in general practice, conducted by the staff of the Menninger Clinic, Topeka, will be held April 19-24. This year the course will include a brief introduction to the fields of neurology and psychiatry and a specific application of this knowledge to the large group of cases of psychoneuroses, psychoses and psychogenic and neurologic disorders which the physician meets in everyday practice.

**Bills Introduced.**—H. 256 proposes to create a state pedopractic board of examiners and to regulate the practice of pedopractic. Pedopractic is defined by the bill as "the diagnosis and treatment of all illnesses of the human foot." H. 162, to amend the workmen's compensation act, proposes to make compensable any injury or disease which arises out of or in the course of any employment. H. 226 proposes that all applicants for licenses to practice any form of the healing art, as a condition precedent to their right to present themselves to their respective professional boards for examination and licensure, must pass examinations in anatomy, physiology, chemistry, bacteriology and pathology, to be given under the direction of the state board of education. To aid it in conducting these examinations the state board of education is to be empowered to employ professors, associate professors or assistant professors from the science departments of accredited colleges and universities of the state, provided, however, that no such person may be selected from the University of Kansas or its School of Medicine or be a practitioner of any healing profession.

### MARYLAND

**Bills Introduced.**—S. 61 proposes to grant to hospitals, treating persons injured through the negligence of others, liens on all claims, rights of action, compromises, and judgments accruing to the injured persons because of their injuries. H. 137 proposes to empower equity courts to authorize the sexual sterilization of incurable idiots, imbeciles or morons, residents of the state whether inmates of state institutions or not.

**Dr. Eagle Awarded Prize.**—Dr. Harry S. Eagle, passed assistant surgeon, U. S. Public Health Service, at present stationed at Johns Hopkins Hospital and lecturer in medicine at the Johns Hopkins University School of Medicine, Baltimore, has received the Alvarenga Prize for 1936 of the College of Physicians of Philadelphia, for his essay on "The Present Status of the Blood Coagulation Problem." Dr. Eagle graduated from Johns Hopkins University School of Medicine in 1927. Until recently he was assistant professor of bacteriology at the University of Pennsylvania School of Medicine. At the annual meeting of the Society of American Bacteriologists in Indianapolis, Dec. 29, 1936, Dr. Eagle was presented with the \$1,000 prize and gold medal of Eli Lilly and Company, for accomplishments in research on various diseases, notably syphilis. The Alvarenga Prize was established through a legacy received by the College of Physicians of Philadelphia in 1888 from the late Pedro Francesco da Costa Alvarenga, Lisbon, Portugal, an associate fellow of the college. The interest from this fund constitutes a prize which is given to the author of the best unpublished, competitive essay on any subject in medicine.

### MASSACHUSETTS

**Bills Introduced.**—H. 1489 proposes a system of compulsory and voluntary sickness insurance, whose benefits are to consist of cash and all forms of medical and dental services. Persons employed at "other than manual labor" and receiving wages in excess of \$60 a week, farm laborers and persons employed by an employer having less than three employees in personal or domestic services, are to be excluded from the compulsory insurance of the bill but are to be entitled to participate in the voluntary insurance. This bill appears to be identical with the so-called Epstein bill, prepared by the American Association for Social Security, Abraham Epstein, secretary. H. 1163 proposes to establish a board of magnetic healers examination and registration and to regulate the practice of magnetic healing. The bill proposes that "the system, method or science commonly known as magnetic healers [sic], or the practice of magnetic healing, is defined to be the science of reviving and producing life and circulation in the nerve system and cells, so as to heal all nerve affections." Apparently no educational requirements

whatever are to be exacted of applicants for such a license and an applicant need only to show that he is 21 years of age and "capable of examining nerve conditions by his magnetic power." H. 1200, appendix XXXV, proposes to prohibit the retail sale of barbituric acid or of dinitrophenol except on the written prescription of a physician. H. 1200, appendix L, proposes to prohibit the establishment, maintenance or operation of hospitals except by virtue of an annual license issued by the department of public health. No such license will be issued by the department unless the appropriate local board of health shall have first certified to the department that the hospital is approved as to location and equipment by such board. The department is to have supervision of all such hospitals and is authorized to make necessary rules for their regulation. H. 1200, appendix LI, proposes to prohibit the establishment, maintenance or operation of nursing homes except by virtue of a license issued by the department of public health. No such license will be issued by the department unless the local board of health shall have first certified to the department that the nursing home in question is approved as to location and equipment by such board of health. H. 1200, appendix LV, authorizes the admission of inebriates and drug addicts to institutions under the supervision of the department of mental diseases. H. 1200, appendix LVI, proposes to establish a commission of five members, to be appointed by the governor, to investigate and study all aspects of occupational diseases and any methods or ways or means of reducing or controlling the hazard or the likelihood of contracting occupational diseases.

### MICHIGAN

**Bill Introduced.**—H. 127, to amend the workmen's compensation act, proposes, in effect, to make compensable "any disease . . . proximately caused by and arising out of and in the course of" employment.

**Dr. Edmunds Chosen Russell Lecturer.**—Dr. Charles W. Edmunds, professor of materia medica and therapeutics, University of Michigan Medical School, Ann Arbor, has been selected to give the Russell Lecture for 1937 at the university. The lectureship is awarded annually to a member of the faculty of the University of Michigan who has distinguished himself by outstanding scholarship. Dr. Edmunds is the twelfth lecturer and the fourth to be chosen from the medical faculty. The lecture will be given sometime in the spring and the subject one related to Dr. Edmunds' specialty.

### MINNESOTA

**Bill Introduced.**—S. 479, to amend the chiropractic practice act, proposes to make the annual renewal of a license to practice chiropractic contingent on the attendance of the licensee during the preceding year at "at least one of the two-day educational programs as conducted by the Minnesota American Chiropractic Association, Inc., the subjects of such programs being under the supervision of the State Board of Chiropractic Examiners."

### MISSOURI

**Bill Introduced.**—H. 188, to supplement the osteopathic practice act, proposes to require licensed osteopaths to register annually and to pay annual renewal fees of \$2.

**New State Health Commissioner.**—Dr. Harry Field Parker, Warrensburg, has been appointed health commissioner of Missouri, succeeding Dr. Elmer T. McGaugh. Dr. Herman S. Gove, Linn, has been serving as temporary health officer since Dr. McGaugh's resignation. Dr. Parker graduated from Washington University School of Medicine, St. Louis, in 1906.

**Operative Clinics.**—The Kansas City Southwest Clinical Society announces the inauguration of operative clinics each Tuesday morning at the Allied Hospitals of Greater Kansas City. Tuesday was selected to afford visiting physicians the opportunity to attend that evening the meeting of either the Jackson County or the Wyandotte County Medical Society.

**Dr. Yancey Retires as Medical Director of Railway.**—Dr. Edwin F. Yancey, Sedalia, has retired as medical director of the Missouri-Kansas-Texas Railroad Company, effective February 1, it is reported. Dr. Yancey has served continuously with the company since 1885, taking over the duties of chief surgeon on Jan. 1, 1891. A native of Missouri, Dr. Yancey is 78 years of age. He graduated from Missouri Medical College in 1882.

**Joint Meeting on Gynecology.**—The St. Louis Gynecological Society and the Chicago Gynecological Society held a joint meeting in St. Louis, February 13. Dr. Joseph L. Baer, Chicago, discussed "Selective Treatment of Prolapse of the

splanchnicectomy, renal function that has been previously impaired improves and may even return to normal.

In view of the extremely unfavorable prognosis of malignant hypertension, experimental attempts at its relief by surgical procedures, although still uncertain, appear to be justified in selected cases. Reports of further experience in institutions where such cases may be studied completely will no doubt yield evidence on which a definite evaluation of the method may be based.

#### CONTINUOUS DRIP BLOOD TRANSFUSION

Rapid introduction into the blood stream of a number of substances was shown by Hyman and Hirshfeld<sup>1</sup> in animal experiments to result in a state of shock characterized by a rapid fall of the blood pressure, irregularities of respiration and lack of coagulability of the blood. The reaction depended not so much on the nature of the substance as on the speed with which it was introduced. They therefore referred to it as "speed shock." They have also shown the tremendous tolerance on the part of the body to large intravenous doses of many substances and to the introduction of a great bulk of fluid, provided the rate of flow is reduced to 2 or 3 cc. per minute. Applying the drip method in clinical practice, these authors found it of great value in the prophylaxis and treatment of shock and hyperthyroidism, hemorrhage, coma, uremia and sepsis. They recommend that the flow be regulated to from 30 to 35 drops per minute.

Along with the brilliant results obtained with the method of blood transfusion, the clinician has encountered a number of failures. There is a group of cases characterized by a severe acute anemia and a lowered regenerative hematopoietic function in which the customary single so-called massive transfusion of a pint of blood fails to produce the desired effect. A still larger single dose is not safe, because of a possible embarrassment to the cardiovascular system. For such cases Marriott and Kekwick,<sup>2</sup> working in the Middlesex Hospital, London, conceived of the advisability of administering larger amounts of blood by the continuous drip method. They define "drip transfusion" as a large transfusion administered very slowly. They suggest that the dose of blood transfused be regulated by hemoglobin determination with the purpose of restoring the hemoglobin percentage to the neighborhood of the lower limits of normality—80 per cent. In the average adult, a pint of blood is equivalent to 10 per cent of the total hemoglobin and can increase the total percentage present only by that amount. The donors should all be compatible with the recipient and of the same group as one another to avoid agglutination.

Eighty-seven intravenous drip transfusions were performed at the Middlesex Hospital during 1935. The

principal technical difficulty encountered in the use of citrated blood for drip transfusion was that the corpuscles tend to sediment in the reservoir and block the drip bulb. The authors have overcome this difficulty by bubbling a continuous stream of filtered oxygen through the blood, thus accomplishing a continuous stirring. They recommend a rate of flow of 40 drops per minute. The average amount infused per hour amounted to 133 cc., or 1 liter in seven and one-half hours. The largest single transfusion amounted to 6.3 liters, and the longest transfusion occupied sixty-two hours. The method was applied in cases of hematemesis and melena from peptic ulcer, in acute anemias from hemorrhage, in acute hemorrhagic colitis, as a preoperative measure, and in leukemia and purpura. They were able by this method to raise the hemoglobin from 20 or 25 to 90 or 100 per cent. The results were excellent and in some of their cases extraordinary.

Vinograd-Finkel, Dulcin and Yurovskaya,<sup>3</sup> reporting from the Central Institute of Hematology in Moscow, while essentially agreeing with the English workers, stated that in all their cases transfusions were accompanied by a febrile reaction. One or two hours from the beginning of the transfusion, when the patient had received about 200 cc. of the blood, there was a chill followed by a rise of temperature to 39 or 40 C. (102 to 104 F.). The febrile reaction lasted until the end of the transfusion and returned to normal in twenty-four hours. In spite of the protracted reaction, no untoward symptoms were noted in their sickest patients. The authors were particularly impressed with the safety of the slow method of blood transfusion. The advantages of the method appear to be that it allows introduction of much greater amounts than heretofore practiced and in its greater safety and more pronounced therapeutic effects.

#### HEALTH AND DISEASE IN THE MAGAZINES

In the *Ladies' Home Journal*, March 1937, Paul DeKruif writes on "The New Weapon Against Infantile Paralysis." In brief the article points out that infantile paralysis invades the body by way of the nose, presumably passing from the olfactory nerves to the brain and the spinal cord; that Armstrong and several other workers in the United States Public Health Service have shown that the spraying of these nerves with a picric acid-alum mixture prevented infection in monkeys, and that in mass experiments in the Southern states the method seemed to have value in human beings. The article indicates that workers in the University of Michigan determined that in most instances, unless the spraying was done in an exceedingly accurate manner, the spray failed to reach the olfactory nerves and thus failed of its purpose. It concludes with the evidence recently developed by Schultz and his co-workers in Stanford University that a 1 per cent

1. Hyman, H. T., and Hirshfeld, Samuel: Studies of Velocity and the Response to Intravenous Injections, *J. A. M. A.* 96:1221 (April 11) 1931.

2. Marriott, H. L., and Kekwick, A.: Continuous Drip Blood Transfusion, *Lancet* 1:977 (April 27) 1935.

3. Vinograd-Finkel, Dulcin and Yurovskaya: *Sovet. khir.*, 1936, No. 7.

service, and pass examinations to be conducted by the board. A chiropractor may not designate himself as a physician or surgeon but may use the prefix "Doctor" before his name, provided his name is followed by the word "Chiropractor." S. 160 provides for the prevention, treatment, cure and control of venereal diseases. It proposes (1) to prohibit the employment of any person handling food products or drinks unless such person is free from venereal disease; (2) to make it a felony for a person infected with a venereal disease in a contagious form to marry or to expose any other person by the act of copulation to such venereal disease; and (3) to make it a condition precedent to the issue of marriage license for both parties to the proposed marriage to present a physician's certificate that the parties are not infected with any venereal disease in a contagious form. A physician examining any person for a venereal disease must charge a reasonable fee therefor, one dollar of which is to be set aside in the county treasury of the county in which the examination was made, in a special fund to be used for the enforcement of the act. The bill also proposes that any person not a licensed physician who undertakes for pay to treat or cure any person infected with venereal disease shall be guilty of a felony. S. 190, to amend the chiropractic practice act, proposes, among other things, to define "chiropractic" as "a system of adjustment consisting of Palpation, Radiograph or other Method to ascertain Vertebral Subluxations of the Spinal Column, or the Articulations of the Skeletal frame, followed by the adjustment of them by Hand alone in order to relieve interference with the normal Nerve Force from the Brain to the rest of the body. This definition is inclusive and any and all other methods are hereby declared not to be Chiropractic." H. 270, to amend the medical practice act, proposes that (1) the governor appoint the seven members of the board of medical examiners from the schools of practice commonly known as the regular, the eclectic, the homeopathic and the physio-medical schools and that at no time shall there be a majority of one school represented on said board; (2) the license of a physician cannot be revoked before a trial of charges by the board of medical examiners nor before the decision of the board of medical examiners becomes final; (3) in revocation proceedings, failure of the accused physician to file a written answer with the secretary of the board within twenty days after the service of charges on him shall work a revocation of his license; (4) the term "cappers and steers," the employment of whom by a licentiate is unprofessional conduct and grounds for the revocation of a license, shall not be construed to apply to persons soliciting contracts for professional, surgical, medical or hospital services to be rendered in the future on behalf of organized groups, hospitals, clinics or cooperative organizations, and (5) appeals from orders of the board of medical examiners revoking or suspending licenses be taken, not directly to the supreme court as the present law provides, but to the district court of the county in which the accused resides or to the district court of the county in which the hearing on the revocation proceedings was had, and that on such appeal to the district court the matter be tried de novo by a jury.

### OREGON

**Bills Introduced.**—H. 143 proposes that in any action in which the mental or physical condition of a party is involved, the trial court may order him to submit to an examination as to his physical or mental condition. S. 182 proposes that before any state-aided home or institution, caring for venereally infected children under 21, can receive any state aid, said home or institution must first obtain a license from the state child welfare commission. H. 243, to amend the law relating to examinations in the five fundamental sciences required of all applicants to practice any form of the healing art as a condition precedent to their right to present themselves for examination and licensure by their respective professional boards, proposes that it shall not be necessary for an applicant to secure a passing grade in all of the required subjects in any one session of examinations held by a state board of higher education. The bill proposes that any applicant who obtains a passing grade of 75 per cent in each of three or more of the required subjects in any session of examinations shall thereafter be examined only in the subjects in which he failed. H. 272 proposes that when any clinic, institute, or any group or combination of persons practice the healing art and use an assumed name, or "clinic," "institute," "specialist" or other title, there shall be likewise added after such title on any written or printed material, or in connection with any advertising, the names and correct designations of the persons connected with the group. H. 352 proposes to make it a misdemeanor for a hospital, exempt from taxation, to deny the use of its facilities to any reputable or qualified licensed physician, solely on the ground

that such physician is not a member of a local, state or national medical society or association, or to refuse to make such facilities available to such physician on the same basis as they are used or made available for the use of physicians who are members of any local, state or national society or association.

**Bill Passed.**—H. 246, to amend the medical practice act, has passed the house. It proposes (1) to authorize the board of examiners to maintain a suit for an injunction against any unlicensed person practicing medicine; (2) to make it the duty of every licensed physician to display his certificate of annual registration in some conspicuous place in his office; (3) that if a licentiate fails to pay his annual registration fee his license shall be revoked by the board on twenty days' notice given him of the time and place of considering such revocation, and that no license shall be revoked for such nonpayment if the licentiate so notified pays before or at the time of such consideration the fee required and such penalty as may be imposed; and (4) to designate various additional acts as unprofessional conduct, which is a ground for revoking a license, such as employing solicitors, or paying or presenting any person with money or anything of value for the purpose of securing patients; holding oneself out to treat human ailments by making false statements, by specifically designating any disease, or group of diseases and making false claims of one's skill or of the efficacy of one's medicine; advertising in any manner, either in his own name or in the name of another person or clinic or concern, actual or pretended professional superiority to that possessed by fellow physicians, the restoration of lost manhood, the treatment of private diseases peculiar to men or women, or the advertising or holding himself out to the public in any manner as a specialist in the diseases of the sexual organs or the diseases caused by sexual weakness, self abuse or excessive indulgence; and aiding or abetting the practice of any of the healing arts by an unlicensed person.

### PENNSYLVANIA

**Bills Introduced.**—H. 458 proposes to establish a state board of chiropody examiners and to regulate the practice of chiropody. The bill proposes to make "chiropody" and "podiatry" synonymous and proposes that the terms mean "the diagnosis and treatment of the human foot and leg (amputation of the leg, foot or toes excepted), the making of models of the human foot, and the palliative, manipulative, electrical and mechanical treatment of the foot and leg as taught and practiced in the schools or colleges of chiropody recognized by the State Board of Chiropody Examiners." H. 490 proposes to establish in the department of public instruction a board of chiropody examiners, to consist of the superintendent of public instruction, ex officio, and three chiropodists, to be appointed by the governor. H. 622 proposes a system of compulsory and voluntary sickness insurance whose benefits are to consist of cash and all kinds of medical and dental services. All employees are embraced in the compulsory insurance of the bill except farm laborers and personal or domestic servants of an employer having less than three employees engaged in such service, which persons, however, are to be entitled to participate in the voluntary insurance.

### RHODE ISLAND

**Bill Introduced.**—S. 35 proposes to grant to physicians, hospitals, nurses or dentists, treating persons injured through the negligence of others, liens on all claims, judgments or compromises accruing to the injured persons by reason of their injuries.

### TEXAS

**New State Health Officer.**—Dr. George W. Cox, Del Rio, has been named state health officer to succeed Dr. John W. Brown, who has served four years. Dr. Cox is 57 years old and was graduated from Tulane University of Louisiana School of Medicine in 1906.

**Society News.**—At a meeting of the Dallas County Medical Society, February 11, the speakers were Drs. Elliott Mendenhall, on "Modern Concepts in the Treatment of Tuberculosis"; Alfred I. Folsom and Harold A. O'Brien, "Use of Mandelic Acid in Urinary Infections," and George T. Caldwell, "Systemic Torulosis."

**Bills Introduced.**—H. 325 proposes to reorganize the executive department of the state government. Among other things, the bill proposes to create in the department of public health a bureau of licensing which is to assume all the functions heretofore vested in the state boards of medical examiners, of nurses, of barber examiners, of chiropody examiners, of dental examiners, of embalming, of pharmacy, and of optometry. The bureau to be created is to be provided with a staff qualified

or similar products will occur. For the sake of consistency in nomenclature and to avoid confusion in medical literature, physicians and investigators should bear in mind distinctions between the following terms: Insulin as a term for the unmodified insulin of commerce. Protamine Insulin as a product essentially that described by Hagedorn, to which no zinc salt has been added.<sup>5</sup> Protamine Zinc Insulin for the product modified by the addition of protamine and a zinc salt, with other substances, and commercially available under the name Protamine Zinc Insulin.

### OSTEOPATHY SEEKS FEDERAL APPROVAL

Maybe Congress will say that osteopathic manipulations and similar performances are good enough for sick and injured employees of the federal government. It is asked to do so by enacting a bill recently introduced by Senator Burke of Nebraska, S. 1233, and Representative Drew of Pennsylvania, H. R. 4650. Employees of the federal government are now entitled, under the United States Employees Compensation Act of 1916 as amended, to the services of qualified physicians, at government expense, when they are disabled by injury or disease arising out of the discharge of duty. The bill proposes to define the term "physician" so as to include osteopaths and to define the phrase "medical, surgical and hospital services and supplies" so as to include the services and supplies of osteopaths and osteopathic hospitals. If the Committees on the Judiciary of the Senate and the House of Representatives, to which this bill has been referred, give it serious consideration they will no doubt make the kind of investigation made in Great Britain to determine the soundness of the osteopathic hypothesis. They should find out how the practice of osteopathy today differs from the practice of medicine. They should look into the adequacy of osteopathic education and the suitability of osteopathic hospitals for the care of government employees. Without such investigations, intelligent action will be impossible. Notwithstanding the wide legislative recognition that has been given to the osteopathic cult, neither Congress nor any state legislature has ever seriously investigated it. The recent investigation by a select committee of the House of Lords resulted in the ignominious retreat and surrender of the osteopathic proponents of legislation then pending in parliament; they retired when they were confronted with the necessity for justifying the existence of osteopathy as a specific method of treating the sick. If the bill is passed, we may expect efforts to procure an osteopathic corps for the army, including an osteopathic veterinary corps, osteopaths in the naval service, an osteopathic public health service, an osteopathic bureau in the Veterans' Administration, and possibly osteopathic veterinarians in the Department of Agriculture. The farmers would find it interesting and amusing to apply osteopathic prophylaxis, diagnosis and treatment to sick and injured horses, cattle, sheep and swine.

5. Prior to the adoption of the name "Protamine Zinc Insulin" some preparations comprising protamine, zinc and insulin were supplied and referred to in publications under various designations, including the designation, "Protamine Insulin."

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ALABAMA

**Bills Passed.**—S. 54 XX has passed the Senate, proposing to create a board of medical technician examiners, to regulate the practice of medical technicians and to prohibit a person from practicing as a medical technician unless licensed by the board. The bill proposes to define "medical technician" as "a person who is engaged in the practice of standardized or experimental technical procedures, the results of which are interpreted by the physician in the diagnosis of disease. Provided, that this shall not apply to assistants employed by physicians to make laboratory tests whose results are to be used by such physicians in their private practice of medicine and who assume responsibility for the work so performed." H. 330 XX has passed the house proposing to impose an annual occupational tax on a person engaged in the practice of medicine, bacteriology or roentgenology of \$25, if the licentiate practices in cities or towns of over 5,000 inhabitants; of \$10, if the city or town in which the practice is carried on is from 1,000 to 5,000 inhabitants; and of \$5, if the practice is carried on elsewhere.

### ARKANSAS

**Bill Passed.**—S. 123 has passed the senate, proposing to create a chiropody examining board and to regulate the practice of chiropody. "Chiropody (sometimes called Podiatry)," the bill provides, "shall for the purpose of this act, mean diagnosis, medical, electrical, mechanical and surgical treatment of ailments of the human feet and massage and manipulation in connection therewith."

**Arrest of Fraudulent Representative.**—Albert Herschel Craven, self-styled student of criminology, was arrested January 26 when police were informed that he accepted \$5 from Dr. James A. Foltz, Fort Smith, in payment for a cooperative insurance policy. Craven had been calling on physicians in Arkansas in the interest of the Cooperative Automobile Association, Inc., of Nashville, with a plan for legal medical and mechanical assistance to automobile owners which involves the listing of approved garages, attorneys and physicians. His "sales activities" were described in the Organization Section of THE JOURNAL, January 16, page 24B, and it is to this notice that Craven's apprehension is attributed. Dr. Davis W. Goldstein, Fort Smith, called the secretary of the Arkansas Medical Society, Dr. William R. Brooksher, Fort Smith, who notified the sheriff. The Cooperative Automobile Association, Inc., of Nashville, is not licensed to do insurance business in either Tennessee or Arkansas and is not authorized to do business in Arkansas as a service corporation. Craven and his wife were charged with bringing a stolen car into Fort Smith and with attempting to obtain money under false pretenses from physicians in the community, newspapers reported. He declared that he was willing to be committed to Tucker prison farm so that he could continue his study of criminology. In referring to his insurance scheme, Craven explained that he selected his prospects carefully, preferring doctors and lawyers. He said it was interesting to see how the public can be fooled and how many people get taken in on schemes. He admitted having collected about \$500 in this "racket."

### CALIFORNIA

**Bills Introduced.**—A. 1640 proposes to repeal the act for the regulation and control of corporations organized for the purpose of operating nonprofit hospital service plans, approved July 5, 1935. A. 1132 and A. 1641 propose to regulate and control corporations organized for the purpose of operating nonprofit hospital service plans and hospitals rendering services under any such hospital service plans. S. 605 and A. 1491 propose to authorize the organization of medical service associations, to regulate their operation and to invest the commissioner of insurance with supervisory and regulatory power over them. The bills propose to authorize such associations to enter into "medical service contracts" with subscribers, which contracts are defined by the bill as agreements "to provide to the beneficiary named therein, in consideration of a sum certain, the professional services of physicians and surgeons for a specified period in the event that the beneficiary is in need thereof." A. 1283 proposes to authorize persons or associations to engage

### LONDON

(From Our Regular Correspondent)

Jan. 16, 1937.

#### Elaborate Preparations Against Attacks with Poison Gas

Britain will soon be the first country in the world to have gas masks available for the whole of the civil population of the capital. Scientific and technical experts have worked out a difficult and new problem: how to produce a simplified and improved gas mask, which can be made by the million by mass production methods. At a factory established by the government the output will soon be half a million masks a week and it is proposed to make 30 million, sufficient for the whole civilian population. The components of a gas mask are a light metal container filled with activated charcoal, several pieces of wire gauze, a thick wad of absorbent cotton, some layers of muslin fabric, metal springs and a rubber mask or face piece into which the container is fixed. The mask fits securely under the chin over the mouth, cheeks and eyes. A cellulose acetate window permits vision. The mask is fixed to the head by easily fitting elastic straps.

At the formal opening of the factory for assembling the containers of gas masks, Mr. Lloyd, parliamentary undersecretary for the Home Department, said that the government considered that in time of war every one ought to have a gas mask, whether he had money to buy it or not. That was the reason why the factory had been established for mass production of gas masks. It was hoped that they never would be needed, but if they were the government would issue them free of charge to every one in danger. The face pieces of the mask, being of rubber, are stored in an inert gas, which will protect the rubber from deterioration for a long time, but there will be periodic tests of the face pieces and containers to ensure that they are in good condition. The charge in the container will last in use against a gas attack from thirty-six to forty-eight hours. Regional depots for gas mask storage are being established.

In the case of an air raid the government considers that the right place for a civilian is indoors in a room in which certain simple precautions have been taken—pasting paper over openings and stopping up cracks with sodden newspaper. Such a refuge room would be the first line of defense. But the government thinks it vital to have a second line of defense, in the shape of the gas mask, for use in case the gas-proof room is damaged, or to enable a person caught outdoors in poison gas to go to a place of safety. Arrangements will be made for any person who wishes to try on the new mask to do so. The masks have been tested and found efficient against every poison gas known to the government. Though vitally important, their provision is only one form of a great national defense against air raids which is being built up all over the country. The local authorities will soon be asking for volunteers to help in air raid precaution organizations.

A census has been taken of the slum property in London where the houses cannot be made gas proof. In the event of an air raid it is proposed to have a voluntary and organized evacuation. This is being worked out with railway companies. By the system of giving warning of air raids, all the country should know in from seven to ten minutes that raiders have passed the coast. Arrangements are being made for getting convalescent cases out of hospitals that are likely to be required for air raid casualties and moving them from the more vulnerable sections of the metropolis to remoter institutions. Consultations are taking place between the government and the authorities of the hospitals. What the government considers an excellent provision has been made by the Westminster Hos-

pital, which is being rebuilt and is in a particularly dangerous position, near the houses of parliament. A covered road will run through the hospital, so that casualty cases can be sheltered at once from further bombing, instead of having to wait outside unprotected. This road will be air locked and have paths communicating direct with the wards, rendering admission of poison gas impossible.

#### Research on Cancer

The director of the Imperial Cancer Research Fund, Dr. W. E. Gye, has presented in his annual report a review of the present position of cancer research in this country. Interest has now shifted from the study of transplanted tumors to carcinogenesis. Among the influences that can excite cancer formation are ultraviolet radiation, x-rays, radium, purely physical agents, a wide range of chemicals such as arsenic, aniline, tars, dyestuffs, complex hydrocarbons and gross animal parasites. Some of the chemical carcinogenic compounds are of exceptional interest, as their chemical structure is closely related to that of substances, the sterols, which occur in the body. The best known and commonest sterol is cholesterol, a complex alcohol, which occurs in all cells and is a constituent of gallstones. By slight change in the sterol molecule bile acids are produced, and the chemical study of these acids and their derivatives and degradation products has provided a link with cancer-producing hydrocarbons. In 1933 Wieland and Dane obtained from the bile acid deoxycholic acid, a product that has assumed great importance in the study of cancer. It is methylcholanthrene and when painted on mice produces cancer more quickly than any substance known. Its dominant interest is the fact that it is produced from substances always present in the animal body. Moreover, the series of chemical reactions by which it is obtained in the laboratory are of the kind that occur in the body under the influence of cell enzymes. The conception has arisen that normal cells when placed under abnormal conditions produce abnormal derivatives of sterols which are carcinogenic.

Even if this hypothesis should be proved to be true it would not afford a complete explanation of cancer. It is now known that cancer begins as a change in a single normal cell or small group of normal cells, which acquire the power of autonomous growth. In the previous annual report of the fund it was emphasized that numerous experimental observations show that the factors which confer on a cell the property of autonomous growth reside within it and cannot be attributed to agents acting from without, though these may be a remote cause. A list of the remote causes has been given. They prepare the area on which they act for the intrinsic changes of cancer. In other words, they produce a "precancerous" condition.

#### The Physical Training of Medical Students

Much attention is being given in this country to physical training. Dr. Donaldson has brought forward a scheme for the students of St. Bartholomew's Hospital. In an editorial, *St. Bartholomew's Hospital Gazette* asks: Is the physique of the average medical student bad? And if it is bad, is this due to lack of physical training? The *Gazette* answers thus: The standard is much above the general average, but it lends itself to great improvement. The second question raises more difficult issues. As he advances in his course the medical student has little leisure, much less than that of the average artisan or city worker. A recent investigation shows that the average medical student at the hospital spends only 14 cents on his midday meal. As the majority of students live in expensive lodgings where food is often far from being either good or adequate, the *Gazette* asks whether food is not the crucial problem to be settled in any reform of student physique. The proposed scheme of physical training is to be entirely voluntary; any other form would be quite unacceptable. But those most in need of physical culture are those who would not dream of

physicians and surgeons for services rendered during the last sickness shall be given priority over all other claims, except expenses of settling the estate and funeral expenses. S. 1069 proposes a procedure whereby hospitals may be reimbursed for the care and treatment rendered indigent persons injured in automobile accidents. The reimbursement, however, is to be limited to \$6 for each day of care rendered each indigent patient. H. 640 proposes to require every physician having knowledge of any person suffering from poisoning from lead, phosphorus, arsenic, brass, wood alcohol or mercury, or from anthrax or compressed air illness or any other disease contracted as a result of employment, to report the facts within forty-eight hours after obtaining such knowledge to the state department of health. The bill proposes also that a physician making such a report shall receive a fee of 50 cents from the state department of health.

#### DELAWARE

**Bill Introduced.**—H. 88, to amend the workmen's compensation act, proposes to make compensable "such disease or infection as naturally results directly" from employment.

#### DISTRICT OF COLUMBIA

**Medical Bills in Congress.**—*Changes in Status:* S. 84 and S. 989 have passed the Senate, proposing, respectively, to provide for the issuance of a license to practice the healing art in the District of Columbia to Dr. Ralph Charles Stuart and Dr. Clarence Quinton Pair.

#### GEORGIA

**Bills Introduced.**—H. 186 proposes to repeal the existing workmen's compensation act and enact in its stead a new workmen's compensation act. The bill proposes to make compensable not only injuries arising out of and in the course of an employment but also such diseases as can be attributed to the employment. The employer is to furnish such medical, surgical and other attendance or remedial treatment, nursing and hospital service for such period as the nature of the injury or the process of recovery may require. The employee is to be permitted to select his own physician only in the event that the employer fails to provide one. H. 250 proposes to authorize the formation of nonprofit corporations to furnish group hospitalization service to members of subscribers through such hospitals as may be approved by the state board of health, the medical association of Georgia and the Georgia hospital association. The bill proposes to authorize the insurance commissioner to regulate and supervise such corporations and their contracts. Such corporations are not to contract to furnish to their subscribers physicians or any medical services nor to practice medicine in any manner, nor are such corporations to control or attempt to control the relations existing between a member or subscriber and his physician, but such corporations must confine their activities to rendering hospital service only.

#### IDAHO

**Bill Passed.**—H. 123 has passed the house proposing, as a condition precedent to the issuance of a license to marry, that both parties to the proposed marriage present the certificate of a duly licensed physician, dated within ten days prior to the application for a license to marry, showing that each party is free from venereal disease in a contagious stage and is not afflicted with feeble-mindedness or insanity. The bill moreover proposes to limit the fee a physician may charge for executing such a certificate to \$1, including the examination on which the certificate would be based.

**Lectures for Practicing Physicians.**—A group of lectures for physicians in six towns was presented recently under the auspices of the Idaho State Medical Association by Drs. Arthur F. Abt and Garwood C. Richardson and Arthur I. Kendall, Ph.D., all of the faculty of Northwestern University School of Medicine, Chicago. The towns were Pocatello, Twin Falls, Boise, Lewiston, Moscow and Coeur d'Alene. In each town the visiting lecturers addressed one or two meetings for physicians, as time permitted, and one meeting for the public. Dr. Abt's technical lectures were on "Prophylaxis and Treatment of Contagious Disease" and "Mortality and Care of the New-Born." Dr. Richardson spoke on "Infections in Pregnancy and the Puerperium" and "Operative Obstetrics"; Dr. Kendall on "Filterable Viruses," "Intestinal Bacteria," and "Immunization Against Scarlet Fever." Subjects of the public lectures were:

Dr. Abt, Care of the Infant and Child.  
Dr. Richardson, Prevention of Maternal Mortality.  
Dr. Kendall, Conquest of Disease in the Tropics, and How Colonel Gorgas Cleaned Up Panama.

#### ILLINOIS

**Bills Introduced.**—S. 8 proposes to grant to physicians and hospitals, treating persons injured through the negligence of others, liens on all claims, verdicts, judgments or decrees accruing to such persons by reason of their injuries. H. 21 proposes to authorize the sexual sterilization of persons convicted of forcible rape, incest, sodomy or taking indecent liberties with children. The bill also provides that nothing therein contained is to be construed to authorize the operation of castration or the removal of sound organs. H. 95 proposes to authorize the emasculation of persons convicted of the crime of rape, incest, taking indecent liberties with children, sodomy or the crime against nature. H. 97 proposes to appropriate \$200,000 for the purchase of radium and radium equipment for the research and educational hospitals in Chicago.

**Society News.**—Dr. Ralph C. Hamill, Chicago, was reelected president of the Illinois Society for Mental Hygiene at its annual meeting, January 21.—Dr. Ralph B. Bettman, Chicago, addressed the Whiteside County Medical Society at Sterling, January 18, on "Surgical Treatment of Empyema of the Chest."—At a meeting of the Will-Grundy County Medical Society at Joliet, January 20, Dr. Milton Mandel, Chicago, spoke on pneumonia.—The La Salle County Medical Society was addressed, January 21, by Drs. Robert S. Berghoff and Eustace L. Benjamin, Chicago, on heart disease and pathology of the common lesions of the heart, respectively. In the afternoon Dr. Berghoff conducted a heart clinic.—Dr. Daniel L. Sexton, St. Louis, addressed the Madison County Medical Society, Madison, January 8, on "Endocrinology in General Practice."—Dr. Mark T. Goldstine, Chicago, addressed the Peoria City Medical Society, February 2, on "Pelvic Infections."—At a meeting of the Christian County Medical Society in Taylorville, January 27, Dr. Earl O. Latimer, Chicago, spoke on "Abdominal Pain from a Surgical Standpoint."

#### Chicago

**Discussion on Syphilis.**—The Chicago Medical Society devoted its meeting, February 3, to a discussion on syphilis with the following speakers:

Dr. Benjamin Barker Beeson, The History of Syphilis.  
Dr. Frank J. Jirka, state director of health, The General Picture of Syphilis.  
Dr. Guy Howard Gowen, Springfield, Ill., assistant epidemiologist, state department of health, Epidemiology.  
H. J. Shaughnessy, Ph.D., chief of laboratories of the state department, Springfield, Wassermann Test and Its Interpretation.  
Dr. Francis J. Gerty, Syphilis and Insanity.

**Joint Orthopedic and Roentgen Meeting.**—The Chicago Orthopedic Society and the Chicago Roentgen Society held a joint meeting at the Palmer House, February 15, with the following speakers: Drs. John A. Siegling, "Studies on the Development and Growth of the Epiphyses of the Long Bones"; John D. Camp, Rochester, Minn., "Roentgenologic Observations Concerning Intraspinal Protrusion of the Intervertebral Disk in Patients with Sciatic and Low Back Pain," and Myron O. Henry, Minneapolis, "Chip Grafts in Orthopedic Surgery."

**American Medical Association Night.**—The Chicago Medical Society designated its meeting, February 17, "American Medical Association Night." The guests of honor included Dr. John H. J. Upham, Columbus, Ohio, President-Elect, and the following past presidents: Drs. William Allen Pusey, Arthur Dean Bevan, Chicago, and Walter L. Biering, Des Moines. The speakers included Dr. Olin West, Secretary and General Manager of the Association; Dr. Austin A. Hayden, Secretary of the Board of Trustees; Dr. Edward H. Cary, Dallas, Texas, chairman, Committee on Legislative Activities; Dr. Charles Gordon Heyd, New York, President, and Dr. Morris Fishbein, Editor of THE JOURNAL.

#### IOWA

**Bills Introduced.**—S. 31, to amend the laws relating to the election and term of office of boards of trustees of city hospitals, proposes that none of the members of such boards may be physicians or licensed practitioners. H. 117, to amend the workmen's compensation act, proposes to require an employer, with notice or knowledge of an industrial injury, to furnish to the injured employee reasonable surgical, medical, nursing and hospital services, or any other appropriate treatment without limit as to time or amount. Under the present law the employer's liability to furnish such services and treatment is limited in time to the first four weeks of incapacity of the employee and in amount to \$100. H. 124 proposes to authorize the formation of corporations to operate nonprofit hospital service plans whereby hospital care may be provided by the corporation, or by any hospital, to such of the public as become

The third paper in the symposium was "Treatment by Humoral Modification," by Pasteur Vallery-Radot, Haguenau and Hamburger, who reported that the attacks are favored by certain humoral modifications that are still but little known. Certain empirical methods seem to be capable of preventing recurrence of attacks and should be used in all cases of undetermined origin, especially those in which there is a concomitant urticaria or an asthma, and when there is a relation between the attacks and a specific hypersensitivity to certain foods. The methods mentioned were (a) peptone by mouth in doses of 0.5 Gm. one hour before each meal, (b) autohemotherapy, (c) antirabic virus-vaccine, (d) sodium thiosulfate or magnesia, and (e) intravenous injections of sodium carbonate, calcium salts or magnesium sulfate.

The fourth paper on migraine was by Professor Aubertin of Bordeaux, on hepatic treatment. During the past fifteen years, functional disturbances of the liver have been of ever increasing importance, in his opinion. In cases of migraine associated with biliary stasis, the attacks are characterized by excessive vomiting of bile, followed a few days later by a slight icterus, urobilinuria and acholic stools. In the intervals between the attacks, one observes symptoms of digestive disturbances in the form of recurrent nausea and slight tenderness over the region of the gallbladder. The most convincing evidence that the migraine is related to biliary stasis is the amelioration following the use of the duodenal tube combined with magnesium sulfate. About 30 per cent of all cases of migraine are benefited by this treatment. If no other cause, and no evidence of hepatic dysfunction can be found for the attacks of migraine, Aubertin advises a prolonged hygienodietetic disintoxication cure and stimulation of hepatic function. Whether this treatment is specific or not, it cannot do any harm and in his experience has greatly benefited 30 per cent of the cases.

#### Pharmaceutic Substances, Therapeutic Plants and Therapy

For years there has existed a continuous fight between the pharmaceutical industry on the one hand and the pharmacists on the other. The latter have sought to maintain a strong position as the sole dispensers of pharmaceutic substances. Yet, owing to the huge number of ready-made substances now on the market, the pharmacist has been shoved further and further into the background. Then too the fact that the sick insurance societies prefer in their practice the prescription of inexpensive ready-made preparations and recommend these products through the official insurance publications has tended progressively to detract from the importance of the pharmacists. With the coming into power of the National Socialists the pharmacists expected the new régime to undertake drastic measures for the amelioration of the situation and to put an end to this perpetual commercial warfare, through which many of their number had been made to feel real economic distress. But of course the legislators had to consider the sick insurance societies, the total expenses of which must of necessity be commensurately increased if more prescriptions of the type to be filled by pharmacists were to be issued. Nevertheless the new governmental supervisors of medicine and pharmacy are accomplishing far more than their predecessors with regard to administering to the needs of the pharmacist. To be at one and the same time equally just to the two sides is a virtual impossibility and hence any change in the status quo tends naturally to be at the expense of the pharmaceutical industry.

This favorable official attitude toward the pharmacists was further expressed during a recent convention of German pharmacists, at which the governmental representative went so

far as to speak of the ready-to-use products of pharmaceutical houses as "konfektion." This term, which in the German language denotes ready-made merchandise, also may convey a suggestion of inferiority and the speaker no doubt intended that it should do so on this occasion. From the medical point of view there can be scarcely any question that in many cases the personal written prescription to be filled by the pharmacist has its advantages over the recommendation of a ready-made product, but from the same standpoint it is equally undeniable that in other cases the product of the pharmaceutical industry may be just as efficacious as the substance prepared by a private pharmacist on a physician's prescription and in some instances the ready-made product may even be more reliable. A few days ago a pact was concluded between the two rival groups. Under the terms of this agreement the association of pharmaceutical manufacturers and the German Pharmacists' Association are to organize a permanent joint administrative board. It shall be the duty of this board to work out the solution of particular problems and to adhere to the principle of a friendly interchange of views. It is to be hoped that this arrangement will serve the best interests of all concerned. It is interesting to note in view of this recently effected reconciliation that the pharmaceutical industry has composed a "List of New Pharmaceutical Specialties" in which all new pharmaceutical products placed on the German market will find mention. By "new" specialties is meant actual innovations and not mere imitations of products already manufactured and sold by other firms. Pharmaceutic substances which are permitted to be sold elsewhere than at a pharmacy must bear on the package a notice to that effect. No list of such substances can however be complete, as many products are governed by differing regulations according to the use to which they are put. All special substances free sample packages of which are furnished to physicians must carry the plainly visible legend "Sample. Not to be sold." A plethora of physicians' free samples is likewise to be guarded against. Samples of a specialty newly placed on the market shall, after a three year introductory period, be given out only on the request of a particular physician, and unsolicited samples will no longer be supplied. Pharmacists may not accept physicians' samples from the physicians themselves, even as gifts. On the other hand, pharmacists are forbidden to engage in the industrial fabrication of pharmaceutic substances which bear proprietary trade names or otherwise to engage in the wholesale drug trade. The number of differently sized packages of a particular product is also to be curtailed, as these variations have been a source of annoyance to both manufacturer and pharmacist.

The great vogue for so-called therapeutic plants, especially marked in Germany, has also been the subject of previous detailed reports. A "first German Congress of Herbal Medicine" was recently held at Munich in conjunction with an exhibition of pertinent material. The specific results of this congress are not known. In an interesting article that appeared recently in the *Münchener medizinische Wochenschrift* it was suggested that in view of the present increased use of domestic herbs and plants in the manufacture of pharmaceutic substances the utmost care must be exercised in the collection and particularly in the selection of medicinal plants. Dr. Patschkowski has lately described a case of poisoning from "decoction lignorum." The beverage ingested was one of the German medicinal herb teas, the product of an "herb house"; namely, a firm that deals principally in various kinds of therapeutic herbs. The decoction was shown on analysis to contain substantial quantities of root of *Atropa belladonna*. Although only one teaspoonful had been boiled with one cup of tea, manifestations of poisoning appeared three and a half hours after ingestion. In this case, as happens not infrequently, burdock root (*Arctium lappa*) had been mistaken for the root of *Atropa belladonna*.

Uterus"; Noble Sproat Heaney, Chicago, "Operative Indication in Gynecology," and William C. Danforth, Evanston, Ill., "Management of Breech Presentation." Clinical programs were conducted at the Firmin Desloge and St. Louis Maternity hospitals.

### NEBRASKA

**Bill Introduced.**—H. 135 proposes to legalize, under conditions stated in the bill, the administration of euthanasia to persons desiring it and who are suffering from illness of a fatal and incurable character involving severe pain.

### NEW HAMPSHIRE

**Bill Introduced.**—H. 277 proposes that no license to marry shall issue until both parties to the proposed marriage present to the appropriate town clerk a statement signed by a licensed physician that each party has submitted to a Wassermann or Kahn or other similar standard laboratory test and that, in the opinion of the physician, neither party is infected with syphilis or gonorrhea in a stage that may become communicable.

### NEW MEXICO

**Hospital to Be Opened in Taos.**—Mabel Dodge Luhan, Taos writer, has deeded to the Sisters of the Holy Family of Nazareth an \$80,000 house for a hospital. The building, a two-story dwelling with six acres of ground, has been remodeled to accommodate twenty-five patients, with some private rooms, a men's ward and a women's ward. There will be an operating room, x-ray facilities, delivery room and nurses' quarters. The new hospital was to be dedicated January 30 with the name Holy Cross Hospital. Drs. Ashley Pond III, Gertrude U. Light and Warner A. Onstine, all of Taos, make up the medical board.

**Bills Introduced.**—H. 40 proposes to repeal the present workmen's compensation act and to enact in its stead a law creating a state compensation fund to insure employers against liability for compensation and to assure injured workmen of obtaining the compensation to which they are entitled. Workmen, apparently, are to receive compensation only for injuries received in the course of their employment and are to receive such medical, surgical and hospital or other treatment, nursing services, medicines and surgical supplies as may be reasonably required at the time of the injury and within ninety days thereafter, which term may be extended to one year by the industrial commission. S. 70 proposes to create a state department of public health, to consist of the state board of public health, a director of public health, and such other subordinate officers and employees as are authorized. The department is to be responsible for the administration of the public health activities of the state. The state board of health is to consist of five members appointed by the governor and is to formulate all policies, rules and regulations for the conduct of the department's affairs. The director of public health is to be appointed by the board and is to be the administrative head of the department. H. 69 proposes to provide for the hospitalization and treatment of indigent tuberculous persons in hospitals throughout the state having beds available for the hospitalization and medical care of patients suffering from pulmonary tuberculosis and acceptable to the director of public health. The state will pay such hospitals for the care and treatment given accepted patients at the rate of \$2.50 per patient daily.

### NEW YORK

**Award for Research in Ophthalmology.**—The University of Buffalo annually awards a gold medal to the author of some work in ophthalmology. Details can be obtained from Dr. Harold W. Cowper, 543 Franklin Street, Buffalo.

**Bills Introduced.**—S. 481, to amend the pharmacy practice act, proposes to make the provisions of the pharmacy practice act applicable to the sale of proprietary medicines. A. 581 proposes to make it unlawful for any person to grow or permit to be grown on any land any marihuana except as permitted by the bill. The bill authorizes the commissioner of agriculture and market to license persons to grow marihuana on designated land, provided the marihuana is to be used in the manufacture of a commercial product. A. 804 proposes to prohibit a person from practicing as a clinical laboratory technician unless licensed by the education department. The bill defines "clinical laboratory technicians" as "any person who performs any technical laboratory procedures, including bacteriology, bio-chemistry, hematology, clinical pathology, immunology, parasitology, histology or tissue technic, or basal metabolism, which are used for the purposes of diagnosing, investigating or treating any disease, illness or infection."

### New York City

**Laboratory of Industrial Hygiene.**—A laboratory to carry on scientific and industrial work in chemical, bacteriologic and public health problems was recently incorporated under the name "Laboratory of Industrial Hygiene." The officers are Dr. William H. Park, president; Kaufman George Falk, Ph.D., vice president, and Miss Grace McGuire, secretary. The service at present includes units for certified milk, vitamin testing, clinical diagnosis, chemistry and bacteriology.

**Dr. Chapin Honored.**—Dr. Henry Dwight Chapin, professor emeritus of pediatrics at the New York Post-Graduate Medical School and Hospital, was the guest of honor at the annual dinner of the Faculty Association of the school, January 23, at the Hotel Biltmore. The occasion celebrated the fiftieth anniversary of Dr. Chapin's appointment as professor of pediatrics and his eightieth birthday, which was February 4. The speakers at the dinner included Drs. Arthur F. Chace, president of the board of directors; Frederic E. Sondern, former president of the Medical Society of the State of New York; Adolph G. G. De Sanctis, president, and Walter T. Dannreuther, former president, of the Medical Society of the County of New York, and Charles Gordon Heyd, President of the American Medical Association. The faculty association presented to Dr. Chapin a silver loving cup. A native of Ohio, Dr. Chapin graduated from Columbia University College of Physicians and Surgeons in 1881. He is the founder of the Speedwell Society, an organization that has fostered the plan of caring for orphan children in small groups as distinct from the mass care in large institutions. With Mrs. Chapin he also founded the Chapin Adoption Nursery in their New York home. He is a charter member of the American Pediatric Society, of which he was president in 1910. He has been active in many social welfare organizations in New York and in 1933 received a medal from Columbia University "for outstanding contributions to problems relating to the care of children and as a pioneer in hospital social service." He retired from his professorship in 1920. He is the author of numerous books and other contributions relating to pediatrics.

### NORTH DAKOTA

**Society News.**—The Northwest District Medical Society met in Minot recently; Dr. Arthur C. Kerkhof, Minneapolis, spoke on "Gastric Malignancy, Including Gastroscopy and Supervoltage Therapy."

**Personal.**—Dr. John F. Regan, assistant superintendent of the North Dakota Hospital for the Insane, Jamestown, has resigned to become assistant superintendent of the State Hospital for Mental Diseases, Howard, R. I.

**Bills Introduced.**—H. 103 proposes to require the secretary of every board authorized to license persons to practice any profession in the future to file with the secretary of state a certified list of the persons to whom licenses have been issued within thirty days after the issuance of such licenses. H. 161, to amend the medical practice act, proposes to make the failure of a licentiate to pay the required annual registration fee a misdemeanor punishable by a fine of not less than \$50 nor more than \$500, or by imprisonment in the county jail for not exceeding one year, or both. Under the present law a licensed practitioner who fails to register annually within the required time may have his license revoked but such license may be restored on the payment of the delinquent fee and such additional fee, not to exceed \$9, as the board of medical examiners may determine. The bill also proposes that any person convicted for a second time of violating any provisions of the medical practice act shall be guilty of a felony.

### OKLAHOMA

**Bills Introduced.**—S. 155 proposes to repeal the present chiropractic practice act and to enact a new act in its stead. The bill proposes to define chiropractic as "a system of adjustment consisting of Palpation, Spinograph or method to ascertain vertebral subluxations of the Spinal Column, followed by the adjustment of them by hand alone in order to relieve interference with the normal nerve force from the brain to the rest of the body." An applicant to receive a license to practice chiropractic must be 21 years of age, of good moral character, must possess preliminary education equivalent to a high school education, be a graduate of a chiropractic school or college teaching chiropractic and giving a course of instruction of at least three terms of six months each in anatomy, physiology, symptomatology, hygiene and sanitation, chiropractic analysis, chiropractic principles and practices, physical chemistry, histology, pathology, spinography, orthopedia and public health

### The Death of Dr. Van Lint

Dr. J. G. Van Lint died recently at the age of 69. A practicing physician in the city of Gorinchem, he was the founder of the Institute of the History of the Natural Sciences in the Netherlands and in addition he was the first professor of the history of medicine at the University of Leyden. He was president of the international congresses of the history of medicine held at Leyden and at Amsterdam. Dr. Van Lint was the author of excellent works on Vesalius, Boerhaave, Dodonaeus and van Leeuwenhoek. Only last year he gave a lecture on the medicine of ancient Egypt which attracted worldwide attention among groups interested in the historical development of medical science. He organized the historical exhibits of army medical services on the occasion of the sixth International Congress of Military Medicine and Military Pharmacy, held at The Hague in 1931.

### ITALY

(From Our Regular Correspondent)

Dec. 15, 1936.

### The National Congress of Internal Medicine

The forty-second National Congress of Internal Medicine, held recently at Rome, was attended by the directors of all the clinics of the Italian universities and by a large number of foreign professors, among whom were Drs. von Lexer of Munich, Schmieden of Frankfurt and Petit Dutaillys of Paris. Drs. Cesa-Bianchi and Calabresi of Milan were the official speakers on the topic "Physiopathology of Chronic Circulatory Decompensation." Professor Schiassi spoke on a form of chronic insufficiency of the peripheral circulation which originates only in the presence of adhesive pleuritis of the right pleura. The gravest forms are those caused by total adhesive right pleuritis with strong retraction of the right hemithorax, immobility of the right hemidiaphragm, partial stertorous respiration and normal mobility and expansion of the left hemithorax. The speaker believes that this form of circulatory insufficiency is due to pressure on the inferior vena cava and the suprahepatic veins, which are pulled by the left hemidiaphragm during inspiration.

The second official topic, "Nephritis and Nephrosis," was discussed in common by the internal medicine and the surgical societies. Dr. Silvestrini, professor of clinical medicine at the University of Perugia, the speaker for the internal medicine societies, made a critical review of Volhard's classification of nephritis. Inflammation frequently occurs in the nephrotic kidney; there may be different types of inflammation and different intensity of degeneration of the cells of the tubules in glomerulitis; a differentiation of benign from malignant nephrosclerosis is based on the speed of evolution of the disease. The speaker gave a report on experiments performed at the medical clinic of Perugia in which the curve of azotemia was determined, following administration of urea, in rabbits which had been subjected to an operation on the kidney. In cases of nephritis, the operation indicated is that which deals with the foci which cause inflammation rather than with the nephritic kidney. It is advisable, however, to resort to autovaccine treatment before deciding anything about an operation. Professor Mingazzini of Rome was the official speaker for the same subject in the surgical field. Nephritis and nephrosis are rarely treated by surgery. One difficulty is the lack of an exact classification of nephritis. Volhard's classification is still used for establishing surgical indications. The several types of renal operations are nephrectomy, nephrotomy, nephrolysis, decapsulation and innervation of the organ, decortication of the renal artery, chemical sympathectomy of the renal peduncle, paravertebral neurolytic injections and ramisection, which operations, with the exceptions of nephrectomy, nephrotomy and decapsulation of the kidney, are rarely performed. Decap-

sulation of the kidney is frequently done in treating chronic and subacute forms of nephritis. Pousson reported statistics of 153 cases. Decapsulation has not been satisfactory in nephrosis and in certain forms of nephritis. Decapsulation is indicated in hemorrhagic nephritis, which is controlled in all cases by the operation.

The third official topic was "Pathologic Leanness and Adiposity." Professor Galdi of the University of Pisa, with the collaboration of Professors Cassano, Monasterio and Lami, was the speaker. They deny the predominant rôle of appetite as the exogenous factor for the development of adiposity. Disturbances of appetite, which are frequent in persons who are underweight, play a pathogenic part in the development and evolution of leanness. The thyroid is the main motor in the system which produces organic combustion; next in importance are the adrenals. The anterior part of the hypophysis has a direct influence on the regulation of additional energy expended (the so-called luxury metabolism) and also an indirect influence on the basal metabolism by means of the thyrotropic hormone and on the intermediate metabolisms. The insular hormone produces combustion of glycogen, polymerization of dextrose into glycogen and transformation of dextrose into fat. Exogenous adiposity does not exist, regardless of the fact that hyperalimentation and inactivity seem to be of great importance. Hypo-alimentation is the main causal factor of leanness in many cases. In thyroid leanness and in certain forms of essential leanness the basal and additional (luxury) metabolisms are increased. Pathogenic forms of leanness may exist in certain cases regardless of a liberal allowance of energizing substances. Hypophyseal thinness seems to be due to anorexia originating in changes of the diencephalohypophyseal area, in which the center of appetite seems to be located. The origin of adiposity associated with hyperfunction of the hypophysis is unknown. In some cases it seems to be due to hyperadrenalism, secondary to hyperpituitarism. The physiopathology of the pineal body is not yet clearly understood. The thyroid does not play an etiologic part in adiposity. The conception of the existence of a thyroid adiposity is clinical. The rôle of thyroid disturbances in leanness is obvious. Adiposity which complicates gonadal insufficiency or sexual inactivity seems to depend on diencephalohypophyseal disturbances. Climacteric adiposity is constitutional. It is stimulated by the climacteric changes.

The next congress will take place at Turin, and the official topics will be "Chronic Colitis," "Pathology and Treatment of Neurohypophyseal Syndromes" and "Pathology of the Aged." The speakers for the first and third topics will be Professors Ferrata and Bastai, respectively. The second topic will be in common for the internal medicine and surgical societies. The speakers for this topic will be Professors Guglielmo and Chiasserini.

## Marriages

VICTOR E. BROWN, Washington, N. C., to Miss Frankie Lucille Ramseur of Winston-Salem, Nov. 26, 1936.

WILLARD CARDWELL, Greensboro, N. C., to Miss Amelia Martha Hall of New York, Nov. 18, 1936.

ELLA I. DUFF, Boston, to Mr. George Alvah Good of Fredericton, N. B., Canada, Nov. 17, 1936.

JOSEPH PETER MARKEY to Miss Mary Agnes Kretschmer, both of Saginaw, Mich., Nov. 26, 1936.

WILLIAM PERRY MOORE JR. to Miss Mary Elfreth Eggleston, both of Norfolk, Va., Nov. 14, 1936.

JACOB ZERN HEBERLING, Bangor, Pa., to Miss Norma Rebecca Nyce of Jenkintown, Nov. 7, 1936.

JOSEPH M. HITCH, Charlottesville, Va., to Miss Helen F. Goss of Cleveland, Nov. 7, 1936.

ROLAND LINCOLN KESLER, Chicago, to Miss Margaret Lee of Gordon, Neb., Nov. 14, 1936.

to specialize in testing technics and, with the advice and cooperation of members of the several professions and occupations involved, to devise and apply the most effective tests and testing procedures. An integrated field force is to cover the state and to make inspections covering all the occupations and professions subject to license by the bureau. S. 128, to amend the medical practice act, proposes to permit "the application or use of the principles, tenets or teachings of any church in the ministrations to the sick or suffering by prayer, *with or without compensation*, without the use of any drug or material remedy, provided the sanitary and quarantine laws and regulations are complied with."

#### UTAH

**Bills Introduced.**—S. 135, to amend the law prohibiting a physician from being examined in a civil action as to any information acquired by him in attending a patient which was necessary to enable him to prescribe or act for the patient, proposes to permit a physician to testify in probate proceedings concerning the mental condition of his patient. The bill further proposes that (1) where an action is brought for damages on account of the death of a patient, the patient's executor or administrator may consent to the physician's testifying and (2) where the patient brings an action to recover damages for personal injury, such action shall be deemed to constitute a consent by the patient that his physician may testify. H. 156 proposes to authorize the department of registration to license persons "to practice as a naturopathic physician in accordance with the tenets of the professional schools of naturopathy recognized by the department of registration."

#### WASHINGTON

**Bills Introduced.**—Senate Memorial No. 9 proposes to memorialize President Roosevelt and the United States Congress to provide for a survey under the supervision of the United States Public Health Service to determine the number of narcotic addicts in this country and to recommend methods of care and treatment of curable addicts and for a plan for dispensing narcotic drugs to incurable addicts. H. 266, to amend the workmen's compensation act, proposes to authorize "any licensed practitioner in the art of healing" to render the medical care and treatment required by the act to be furnished to injured workers. S. 198 proposes to prohibit the retail sale or distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of conception or venereal diseases except by licensees of the state board of pharmacy and "medical practitioners regularly licensed to practice in the state of Washington." H. 316, to amend the workmen's compensation act, proposes to make compensable "any and all occupational diseases."

#### WEST VIRGINIA

**Bill Introduced.**—H. 188 proposes that applicants for licenses to practice any form of the healing art, as a condition precedent to their right to present themselves for examination to their respective professional boards, must pass examinations in anatomy, physiology, bacteriology, pathology, hygiene and public health, and chemistry, to be given by a board of examiners in the basic sciences. No person may serve as a member of the board who is not a full-time professor, or associate or assistant professor, teaching one or more of the basic sciences, in some university or college in the state accredited by the North Central Association of Secondary Schools of Colleges. No member of the board shall be actively engaged in the practice of healing or licensed to practice healing.

#### WISCONSIN

**Bill Introduced.**—A. 29 proposes to repeal the law requiring antenuptial physical examination.

**Society News.**—Drs. Ernest A. Pohle, Madison, and Merle Q. Howard, Wauwatosa, addressed the Medical Society of Milwaukee County at a joint meeting with the Milwaukee Roentgen Ray Society, January 8, on "The Indications for and the Practical Application of X-Ray Therapy" and "The Suicide Problem" respectively.—Drs. Louis Brachman and Ralph T. Rank addressed the Milwaukee Oto-Ophthalmic Society, January 12, on "Near Vision Problems Confronting the Ophthalmologist" and "Newer Methods of Nasal Therapeutics" respectively.—Dr. Solon Marx White, Minneapolis, addressed the Chippewa County Medical Society, Chippewa Falls, December 8, on "Depression and Increased Irritability in Heart Muscle Function" and "Management of Early Hypertension."

#### GENERAL

**Medical Bills in Congress.**—*Change in Status:* S. 5 has been reported to the Senate, with numerous amendments, proposing to prevent the adulteration, misbranding and false advertising of food, drugs, devices and cosmetics. *Bills Introduced:* S. 1233, introduced by Senator Burke, Nebraska, and H. R. 4650, introduced by Representative Drew, Pennsylvania, propose to amend the United States Employees' Compensation Act so as to provide that the term "physician" shall include osteopathic practitioners and that the term "medical, surgical, and hospital services and supplies" shall include services and supplies by osteopathic practitioners and hospitals. S. 1399, introduced by Senator Chavez, New Mexico, proposes to prohibit the transportation of anhalonium, commonly known as peyote, into any state, territory, or possession of the United States, for delivery, possession, sale, or use in any manner, either in the original package or otherwise, in violation of any law of such state, territory, or possession. The bill further provides that all packages containing any anhalonium, when transported in interstate commerce, shall be plainly and clearly marked, so that the name and address of the shipper, the name and address of the consignee, the nature of the contents, and the quantity of anhalonium contained therein may be readily ascertained on an inspection of the outside of such package. H. R. 1810, introduced by Representative Haines, Pennsylvania, proposes to authorize the President to present a medal of honor to Dr. George E. Holtzapfel, "who administered oxygen in the treatment of pneumonia for the first time on record, March 6, 1885." H. R. 4475, introduced by Representative Voorhis, California, proposes to increase from \$8,000,000 to \$20,000,000 the appropriation authorized by the Social Security Act to assist states, counties, health districts, and other political subdivisions of the states in establishing and maintaining adequate public health services. The bill also proposes to increase from \$2,000,000 to \$5,000,000 the appropriation authorized in the Social Security Act for expenditure by the United States Public Health Service for investigation of disease and problems of sanitation. H. R. 4483, introduced by Representative Rogers, Massachusetts, proposes to authorize an appropriation of \$1,400,000 to construct a veterans' hospital and diagnostic center at or near Boston. H. R. 4485, introduced by Representative Green, Florida, proposes to authorize an appropriation of \$1,000,000 to construct a marine hospital at Jacksonville. H. R. 4598, introduced by Representative Celler, New York, proposes to make it unlawful to sell certain spirits containing alcohol produced from materials other than cereal grains. H. R. 4602, introduced by Representative McKeough, Illinois, proposes to add the name of Gustaf E. Lambert to those listed in the act recognizing the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever. H. R. 4608, introduced by Delegate King, Hawaii, proposes to authorize an appropriation of \$500,000 to erect a veterans' facility in Hawaii. H. R. 4716, introduced by Representative Peterson, Florida, proposes to authorize an appropriation of \$1,500,000 to erect a marine hospital in Florida, the site to be selected by the Federal Board of Hospitalization.

### Government Services

#### Dr. McCoy Relieved as Director of National Institute of Health

Dr. George W. McCoy has been relieved as director of the National Institute of Health, effective January 31. Dr. McCoy had held the position since 1915, when the institute was known as the Hygienic Laboratory. A native of Cumberland Valley, Pa., Dr. McCoy is 60 years of age and a graduate of the University of Pennsylvania School of Medicine, class of 1898. He was appointed assistant surgeon of the Public Health and Marine Hospital Service in 1905 and, in 1913, surgeon in the public health service. He was named medical director in the service July 1, 1930. Dr. McCoy was in charge of the U. S. Plague Laboratory, San Francisco, from 1908 to 1911, and director of the U. S. Leprosy Station, 1911-1915, concurrently serving during this period as sanitary adviser to the Hawaiian Government. He was president of the Washington Academy of Sciences in 1935. He has written numerous papers on bacteriology and public health subjects. Dr. McCoy will be assigned to investigations on leprosy, it is reported.

House of Representatives and of the school committee of Providence; aged 67; died, Dec. 24, 1936, in the Jane Brown Memorial Hospital, of heart disease.

**Herbert Ong Calhoun**, Denver; University of Colorado School of Medicine, Denver, 1920; for many years on the staff of the Agnes Memorial Sanatorium; aged 43; died, Dec. 17, 1936, in the Swedish National Sanatorium, Englewood, of pulmonary tuberculosis.

**John Dawson Carty**, Portsmouth, N. H.; University of Vermont College of Medicine, Burlington, 1906; formerly city physician, health inspector and bacteriologist; trustee of the New Hampshire State Hospital, Concord, for ten years; aged 60; died Dec. 20, 1936.

**Henry Robertson Conway** ♂ Marshall, Mo.; University Medical College of Kansas City, 1912; past president of the Saline County Medical Society; aged 51; on the staff of the John Fitzgibbon Memorial Hospital, where he died, Dec. 14, 1936, of heart disease.

**Samuel Louis Weber** ♂ Chicago; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888; on the staff of the Hospital of St. Anthony de Padua; aged 75; died, Dec. 18, 1936, of coronary embolism and arteriosclerosis.

**Edwin F. Winegar**, Chicago; Chicago Physio-Medical College, 1898; member of the Illinois State Medical Society; formerly on the staff of the Illinois Central Hospital; aged 70; died, Dec. 8, 1936, in a hospital at Phoenix, Ariz., of meningitis.

**Peter Frailey Wells** ♂ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1881; aged 77; died, Dec. 16, 1936, in the Graduate Hospital of the University of Pennsylvania, of carcinoma of the hepatic flexure of the colon.

**Samuel Lee Edwards**, Tuscaloosa, Ala.; University of Maryland School of Medicine, Baltimore, 1899; served during the World War; on the staff of the Veterans Administration Facility; aged 65; died, Dec. 30, 1936, of coronary thrombosis.

**Oscar Francis Shewmaker**, Louisville, Ky.; University of Louisville Medical Department, 1907; member of the Kentucky State Medical Association; on the staff of the Veterans Administration; aged 53; died, Dec. 20, 1936, of heart disease.

**Thomas J. Pendergast** ♂ Milwaukee; Northwestern University Medical School, Chicago, 1893; on the staff of St. Mary's Hospital and St. Vincent's Infants' Asylum; aged 73; died, Dec. 22, 1936, in St. Joseph's Hospital, of heart disease.

**Clement C. Collins** ♂ Roachdale, Ind.; University of Louisville (Ky.) Medical Department, 1892; past president of the Putnam County Medical Society; aged 66; died, Dec. 29, 1936, in a hospital at Crawfordsville, of uremia and nephritis.

**Joseph Reagan Hamlin**, St. Louis; Washington University School of Medicine, St. Louis, 1910; member of the Missouri State Medical Association; aged 51; died, Dec. 27, 1936, in the Missouri Baptist Hospital, of coronary occlusion.

**Samuel Allen Oren**, Lewistown, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1877; State University of Iowa College of Homeopathic Medicine, Iowa City, 1878; aged 82; died, Dec. 9, 1936, of diabetes mellitus.

**Robert L. Thomson**, Almota, Wash.; Kentucky School of Medicine, Louisville, 1880; member of the Washington State Medical Association; aged 80; died, Dec. 10, 1936, in Lewiston, Idaho, of heart disease.

**Thomas W. Treharne**, Zimmerman, Ohio; Detroit College of Medicine, 1892; past president of the Greene County Medical Society; aged 73; died, Dec. 26, 1936, of myocarditis and bronchopneumonia.

**Ralph Dana Goodwin** ♂ East Pittsburgh, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1908; aged 56; died, Dec. 14, 1936, in the Mercy Hospital, Pittsburgh, of coronary thrombosis.

**John R. Cox**, North English, Iowa; State University of Iowa College of Medicine, Iowa City, 1880; aged 83; died, Dec. 22, 1936, in the University Hospital, Iowa City, of arteriosclerosis.

**Henry Middleton Woolman**, Asbury Park, N. J.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; aged 69; died, Dec. 5, 1936, of cerebral hemorrhage.

**Leyden Frederick Wilson**, New Kensington, Pa.; University of Pittsburgh School of Medicine, 1912; aged 48; died, Dec. 13, 1936, in the Citizens General Hospital, of septicemia.

**Wilhelm Nobbe**, St. Louis; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1895; aged 67; died, Dec. 11, 1936, in the Missouri Baptist Hospital, of intestinal obstruction.

## Bureau of Investigation

### MARMOLA

The Federal Trade Commission, in a release dated January 25, stated that it had ordered the Raladam Company of Detroit to cease and desist from certain misrepresentations in the sale of its product "Marmola."

Marmola is an old timer in the obesity-reducing field and has been in difficulties before with the federal authorities. In 1926 the postal authorities were about to issue a fraud order against the Marmola Company when the manufacturer submitted an affidavit declaring that he would absolutely discontinue the Marmola enterprise on April 1, 1927. The manufacturer did discontinue the sale of Marmola through the mails at that time but created the Raladam Company, which continued to sell the product through the retail drug stores—a method not inter-

**GOOD NIGHT, SISTER!  
HAVE A GOOD TIME!**

## SHE WAS TOO FAT!

**And then she made up her mind to get thin and did, without hard exercise or starvation diet**

Nobody loves a fat girl—but why mope about it when you can so easily get rid of that excess fat by means of a tried and true corrective, known and recommended by physicians the world over?

Many years ago medical science discovered that obesity—when an abnormal condition—is caused by the

The excess fat has simply slipped away, revealing the trim and slender figure underneath.

Sounds like a miracle, but thousands of women who have taken Marmola as directed—4 tablets a day—might well tell you it's a demonstrated fact. Indeed, since 1907, more than 20 million packages of Marmola have been purchased—proof positive that nothing succeeds like success. Marmola is put up by one of the leading medical laboratories of America.

Start today! You will soon experience Marmola's benefits. When you have gone far enough, stop taking Marmola. And you will bless the day when you first discovered this marvelous reducing agent!

Marmola is on sale at all dealers—from coast to coast.

selves out with exercising, do not starve themselves, nor drain their systems with drastic purgatives. Yet day by day they have felt lighter, more alert, more energetic. Soon they find their weight satisfactory.

quently employed by "patent medicine" houses in order to stay in business after the issuance of a Post Office fraud order.

In February 1928 the Federal Trade Commission issued a complaint against the Raladam Company, and hearings were held in Chicago, Detroit and Washington, D. C. At the close of the hearings the Federal Trade Commission ordered the Raladam Company, its officers, agents, representatives and employees, to cease and desist from certain representations in connection with the advertising, offering for sale, and sale in commerce in the several states of the United States of the product Marmola (THE JOURNAL, May 4, 1929, p. 1541).

However, the Federal Trade Commission's cease and desist order against the Raladam Company was vacated by the United States Circuit Court of Appeals on June 28, 1930 (THE JOURNAL, Aug 2, 1930, p. 359). The Raladam Company, being freed from the Federal Trade Commission's action, has continued unhampered to dispense its tablets containing desiccated thyroid to the obese.

The present action of the Federal Trade Commission prohibits the representation "that thyroid deficiency is a common or the usual cause of obesity or excess fat or that, if a person

indulging in it unless compelled to do so. There is the difficulty that daily training cannot be carried out without taking time from the hospital curriculum, which is already so full that it sometimes costs the student his midday meal.

#### Dr. J. W. McNee Has Gone to Glasgow

Dr. J. W. McNee, physician to University College Hospital, London, and the leading authority in this country on diseases of the liver, has, at the age of 50, been appointed regius professor of medicine in the University of Glasgow. He has followed the example of Dr. J. A. Ryle, who a year ago exchanged the position of physician to Guy's Hospital for that of regius professor of physic in the University of Cambridge. Dr. McNee has abandoned an assured and leading position in London consulting practice. His student career was passed at Glasgow, so that he has returned to his old school. In 1912 he received a Carnegie traveling fellowship and went to Freiburg, where he studied under Professor Aschoff and made his important observation on experimental jaundice in geese, which is the basis of the modern views of the function of the liver and the reticulo-endothelial cells in the formation of bile. In the war he did important work on trench nephritis, the gas bacillus, wound infection and trench fever. For this he received the D.S.O. He is joint author (with Rolleston) of "Diseases of the Liver, Gallbladder and Bile Ducts" and is associate professor of medicine and associate physician of Johns Hopkins University.

#### PARIS

(From Our Regular Correspondent)

Jan. 21, 1937.

#### Annual Meeting of International Union Therapeutic Society

The International Union Therapeutic Society held its annual meeting at Paris Oct. 14, 1936. The presiding officer, Prof. Maurice Loeper, who is founder of the society, stated that thirty-four countries were represented. The American guests were Drs. Desjardins and Krusen of the Mayo Clinic.

The first paper was by Mouriquand and Viennois of Paris on cevitic acid and its therapeutic indications. The action of this acid on vitamin C deficiency is prophylactic in the stage of nonevident dystrophy and curative in the eutrophic stage. Aside from such indications (vitamin C deficiency) cevitic acid is also useful in hemorrhages of capillary origin, probably because of its aiding the nourishment of the intercellular cement between the endothelial cells of the capillary walls. In certain toxic-infections, such as diphtheria, the toxin of which accelerates the excretion of the cevitic acid of the adrenals, another indication exists. The general resistance of the organism in septicemias is greatly augmented by cevitic acid, which seems to act by supporting the cellular oxyreductions that are so greatly altered in septicemia. It seems to be important for the organism that the nervous and reticulo-endothelial systems should conserve their normal cevitic acid content.

A paper on methods of resuscitation was presented by Cordier of Alfort. Based on experimental work, such as the measurement of pulmonary ventilation and variations of the intracardiac pressure, the Silvester method holds first place among the normal methods of artificial respiration. It must, however, be applied with the subject lying on his back, a fatiguing process for the person who is employing this method, which is still popular in Germany, where it is combined with massage of the heart. The Schafer method ranks very low, if one bases its value solely on the results of experimental work. It is, however, much easier to use than that of Silvester and much less fatiguing for the operator because there is no muscular resistance and the subject lies with the face downward. The feeble action of this method on the ventilation of the lungs and the general circulation can be supplemented by having the arms

raised by a second operator, as suggested by Nielsen, synchronously with compression of the lower part of the thorax by the hands of the first operator, who sits astride the lumbar region of the asphyxiated person. The combined Schafer-Nielsen method has all of the advantages of the Silvester method and is easier to apply. If only one person is available to use resuscitation methods the Schafer method should be used, but if there are two persons available the Schafer-Nielsen method is indicated. Friction and the application of heat are of aid only if the encephalobulbar centers are still excitable.

Hyperpyrexia in gonorrheal complications was the subject of the next two papers, one by Charles Richet and Jean Facquet of Paris, the other by Desjardins and Krusen of the Mayo Clinic. In the first paper it was stated that of thirty-three cases of arthritis treated by hyperpyrexia following injection of dead bacteria there were twenty-eight (78 per cent) complete cures. The statement was made that this method acts more rapidly and is followed by fewer complications than any other. This is true for arthritis, orchitis, endometritis and salpingitis, and even in acute gonorrhea in the male.

Desjardins and Krusen described the Kettering hypertherm apparatus, with the aid of which treatments are given at the Mayo Clinic and in many other American hospitals. Bacteriologic studies have shown that in 99 per cent of the laboratory experiments gonococci were killed at a temperature of 41 C. (106 F.) in five hours and at a temperature of 42 C. (107.6 F.) in two hours. At present an internist, a bacteriologist and a pyrotherapist collaborate in every case. A rectal temperature of 41.2-41.7 C. (a little over 106 and about 107 F.) is maintained for a period of between six and seven hours and the sitting is repeated from one to five times at intervals of from two to three days. Ninety-two per cent of 100 cases (male and female) of gonorrhea (with and without complications) were cured during the past two years. The results were especially striking in gonorrheal arthritis.

In a symposium on the treatment of migraine, the first paper, on the endocrine treatment, was read by Prof. Gregorio Marañón of Madrid. Migraine is a syndrome the fundamental element of which is supposed to be a disturbance of the neuro-vegetative system, which is constitutional and hereditary in the majority of cases. The so-called predisposition to migraine is a vegetative instability, being analogous to the "epileptic predisposition" and also to that of asthma. As in the two last named diseases, the glands of internal secretion play an important part, none however a specific one. A dysfunction of the thyroid can be the underlying factor, or this may be equally true of the ovary, hypophysis, pancreas or other glands of internal secretion. All one can say is that there is a disturbance of equilibrium and not a definite hypofunction or hyperfunction. It is possible by reestablishing a normal hormone state to improve a case of migraine, but the underlying "predisposition" is not cured by such treatment. One ought not to employ the term "endocrine migraines" or speak of "endocrine cures."

The second paper on migraine was read by Professor Parhon of Bucharest, Rumania, and entitled "Rôle of Vascular Spasms and Importance of Antispasmodic Treatment." Parhon also believed that migraine is a constitutional disease, that is, on an endocrine basis, either a hypothyroidism or a hyperparathyroidism being responsible. In the latter, cerebral angiospasms are of much importance. Thyroid and parathyroid opotherapy modify the condition by liberating calcium and acting on the angiospasms. Bromides, phenobarbital, papaverine and the ordinary analgesics act especially on the attacks of migraine. When employed over a prolonged period they seem to have a more or less permanent beneficial effect on cerebral hyperexcitability and tendency to angiospasm and hence on the migraine attacks.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### NEUFELD METHOD OF TYPING PNEUMOCOCCI

To the Editor:—Would you kindly tell me of the Neufeld method of typing pneumococci. If you cannot detail it please tell me where I can find it. Please omit name.

M.D., Maryland.

ANSWER.—In the presence of homologous capsule swelling antibodies, the capsules of pneumococci swell.

The swollen capsule (Neufeld) test for the typing of pneumococci is performed by taking a fleck of sputum or fluid containing pneumococci and adding serums of rabbits made immune to the different types of pneumococci. The serums may be added singly or in groups of several types. When a group is found with which the capsule swells, the individual types contained are tested individually. It is customary to test for type I separately because at least one fourth of the cases are due to this type.

Standard alkaline methylene blue is either added to the mixed sputum and serums or the serum may contain the dye. Reliable serums for performing the test are obtainable from some manufacturers of biologic products (Lederle Laboratories; Parke, Davis & Co.) in capillary tubes or in small vials. Swelling of the pneumococcus capsules occurs with homologous horse serum, therapeutic serum, or serum from patients recovering from pneumonia of homologous type. Such serum may not possess the sharp type specificity of serum prepared in rabbits. Good swelling of the capsules with homologous serum may not appear either because too large an amount of sputum in proportion to the amount of serum is used or because too many organisms are in the exudate or culture in proportion to the amount of capsule swelling antibody. This difficulty is overcome by diluting the exudate with physiologic solution of sodium chloride prior to applying the serum. If all the organisms in a preparation are not swollen by the type applied, it is due to the fact that another type of pneumococcus is present.

When organisms are present in broth, a bile solubility test should be performed.

About three fourths of the cases of pneumococcic pneumonia may be typed directly by the Neufeld examination of the sputum; the remainder may require either mouse inoculation or other methods of study, such as blood culture or aspiration of lung juice. The type obtained by examination of the sputum is correct in 93 per cent of cases. The method is described in detail in the following reference, which gives a bibliography: Bullowa, Jesse G. M., with technical assistance of Somers, Mildred, and Turner, Edward: The Reliability of Sputum Typing and Its Relation to Serum Therapy, *THE JOURNAL*, Nov. 9, 1935, page 1512.

### THIRTEENTH CRANIAL NERVE—RESEARCH IN GROSS ANATOMY

To the Editor:—I have a keen desire to know whether there is anything to the discovery of a thirteenth cranial nerve. I heard some doctors mention it. Also I should like to know whether any gross anatomic discovery of any kind has been made since 1913, when I graduated from the Kansas Medical College—new nerves or glands, brain areas for example. Is any more research being done on gross anatomy and by whom if any? Is it a completely fully worked out subject?

HARVEY P. CHARLES, M.D., Kansas City, Kan.

ANSWER.—The "thirteenth," or extracranial, nerve has often been overlooked. It is the most anterior one (first) in the cranial series, being distributed (in man and mammals) to the upper and anterior part of the nasal septum. It is sensory, homologous with the dorsal spinal and lateral cranial nerves. It is well developed in Amphioxus (sensory from skin anterior end) and is present in practically all higher vertebrates, being easily demonstrable in the fetus of some (man, rabbit), also in the adult of others (horse, ox, dog, cat, squirrel). It consists in mammals of a number of filaments joined in a plexiform way, extending to the anteromedial part of the cribriform plate of the ethmoid, which it perforates in three twigs. It is continued (plexiform) on the lower surface of the olfactory bulb and tract. Behind the bulb its fibers enter the lower surface of the frontal lobe in a series extending back almost to the optic chiasma. It is probable that some sympathetic

fibers join it, as there are a number of tiny ganglions along it, one large one (ganglion terminale) lying on its upper course within the skull. A good account of it in mammals is given by Larsell (*J. Comp. Neurol.*, 1918). He says it is somatic sensory to the epithelium of the nasal septum, and visceral sensory and motor to local blood vessels.

Gross anatomy is not a "fully worked out subject." Formerly it was the chief field in anatomic research. During the last seventy years microscopic anatomy, embryology, neurology and tissue culture have attracted more attention. But work directed partly or entirely to gross anatomy has gone on steadily. The x-rays have afforded a valuable new method of study of living subjects and of changes in form and relations in activity.

Some of the lines along which progress has been made in this century and a few (only) of the workers are: anthropometry, Jackson, Todd, Hrdlicka; anatomy of the child, Symington; growth measurements, Donaldson, Scammon; life history, age and death, Minot, Rolleston, Williams; bone development, Pryor, Grumbach; joints, Fick; muscles and their action, Mackenzie, Wright; position of the viscera in living people, Moody; teeth, Schour; respiratory apparatus, Macklin; heart, MacCallum, Tandler; blood vessels, Adachi, Huntington, Senior; lymphatics, Sabin, Clark, Bartels, Moody, Van Nuss; brain and its growth, Donaldson, Herrick, Ranson; nerves, Bardeen, Tilney, Kerr; comparative anatomy and evolution, Huntington, Parker, Kingsley, Rand. References to recent literature may be found in the bibliographic cards of the Wistar Institute of Anatomy, the *Quarterly Cumulative Index Medicus* and the *Anatomischer Bericht*.

### BRUCELLA INFECTION OF OVARIES AND UTERUS

To the Editor:—Will you please give me what practical data you can on undulant fever. I am interested in whether or not the organism attacks the ovaries and the uterus. What importance do you place on a "positive" skin test when the agglutination is negative? What treatment?

CHARLES L. PHILLIPS, M.D., East Greenwich, R. I.

ANSWER.—There is evidence that Brucella organisms occasionally exhibit a predilection for the genital tract of human beings as in cows or bulls. Kristensen (*Ann. de med.*, 26:339 [Nov.] 1929) isolated the abortus variety of the organism from the exudate, which covered the uterine site of the placenta of a seven months fetus. Carpenter and Boak (*THE JOURNAL*, April 11, 1931, p. 1212) recovered the organism from the tissues of a human fetus that was aborted at the end of the fourth month of gestation. Frei (*Schweiz. med. Wchnschr.*, 59:334 [March 23] 1929) isolated Brucella organisms from the vaginal discharge of a woman who had aborted ten days previously. Leavell, Poston and Amoss (*THE JOURNAL*, Sept. 20, 1930, p. 860) and Kristensen (*Ugesk. f. læger* 90:869 [Sept. 6] 1928) have isolated pure Brucella cultures from infected ovarian cysts. Simpson (*Ann. Int. Med.*, 4:238 [Sept.] 1930) recovered Brucella abortus from a draining sinus tract which extended from the globus major of the epididymis through the scrotal wall. The organism has also been isolated from a tubo-ovarian abscess which developed as a late complication in a case of brucellosis (undulant fever). Orchitis and epididymitis are not infrequent early manifestations of the disease.

The intradermal test, utilizing heat-killed or formaldehyde-killed Brucella organisms, or the standardized Brucella nucleoprotein suspensoid ("brucin") developed by Huddleson, as antigen, is of value in identifying individuals who have acquired cutaneous sensitiveness after the invasion of the tissues by the living Brucella organisms. The skin test is of value in the diagnosis of brucellosis, particularly in those persons (about 5 per cent) in whom no agglutinins for Brucella are found in the blood serum after repeated testing and in those instances in which Brucella cannot be grown on culture of the blood, urine or stools. The skin test is also of value in those cases in which the agglutination reaction is doubtfully positive in low titer (from 1:10 to 1:100). In interpreting the results of the endermic reaction, consideration must be given to the fact that presumably normal persons may develop cutaneous hypersensitiveness without symptoms of illness as the result of previous subclinical (asymptomatic) Brucella infection. Consideration must also be given to the fact that cutaneous sensitiveness remains after recovery from brucellosis. Thus, a person who has cutaneous hypersensitiveness to Brucella antigen may be suffering from some other disease at the time the test is made. A positive skin test may be merely the result of asymptomatic or symptomatic brucellosis acquired some months or years previously.

The opsonocytaphagic test of Huddleson (*Am. J. Pub. Health*, 23:917 [Sept.] 1933) appears to be of considerable value in determining the immunity status of individuals who develop a

But now a serious attempt has at last been made, by Dr. Vollmer of the Pharmacologic Institute of Breslau University, to combat the exaggerated emphasis that has been placed on herbal therapeutics. In an article contributed to the *Süddeutsche Apotheker-Zeitung*, Vollmer makes the point that the question of therapeutic plants has not been nearly so neglected by academic pharmacology as frequent assertions would imply. Nor ought it to be. But the importance of therapeutic plants has in present-day Germany become most grossly exaggerated and one encounters much that is not of clinically verified value. Vollmer enumerates a whole series of plants which, although theoretically capable of producing the effects claimed for them, factually remain of dubious therapeutic worth. Scientific knowledge of the exact action of these substances on the organism is frequently deficient. The author also speaks of the "lack of a basis for the prescription" of such medicaments. All this zeal for herbal medicine is merely a flash in the pan. Many persons have rightly described this movement as a turning back of the clock of time. And all this quite apart from such things as the attribution to a certain plant (savin) of virtues effective only during the odd-numbered months. Furthermore, on the basis of correct enough pharmacologic analyses, incorrect generalizations are formulated. How can a physician retain faith in herbal medicine if at one and the same time four dozen different infusions are recommended to him as spring cures and if an equal number of infusions are recommended for the treatment of climacteric complaints? And all this without the inclusion of a single scientific description of the way in which these mixtures act.

The foregoing observations of a pharmacologist who has remained closely connected with the government are sound.

In addition, a sort of campaign against mysterious panaceas is to be conducted by the National Socialist Health Administration, a campaign against those products which carry neither on their wrappers nor in advertisements any description of the ingredients. Among these are included endocrine preparations, the advertising of which has developed into a nuisance. The most incredible virtues have been claimed for these products and all based on the presence of some mysterious anonymous principle.

Finally, mention should be made on this occasion of the recent trial of a homeopathic physician who was charged with criminal negligence in the deaths of three persons from diphtheria because of his failure to administer injections of serum. The defendant stated that he had treated some twenty other diphtheria cases according to homeopathic methods and none of these cases had ended fatally. In this particular instance, however, a mother and her two children had died, whereas the husband and father, who was ill at the same time, recovered. The physician had refrained from the use of serotherapy, as in his opinion this method of treatment exerts a harmful effect on the organism, whereas homeopathic remedies are innocuous. Moreover, he had refused to permit the calling in of a second physician. The prosecutor asked a sentence of ten months imprisonment but the tribunal acquitted the defendant. In the opinion of this court, a refusal to administer antidiphtheritic serum could not be construed as criminal negligence, since science itself has as yet arrived at no definite evaluation of the serum, a fact that is reflexed by the absence of any law compelling the administration of antidiphtheritic serum. On the other hand, said the court, homeopathy is as much a recognized science as any other (thanks to the present régime) and furthermore no expert had been able to testify that if timely injections of serum had been administered the three deceased persons would have survived. The judgment of this court and the reasons alleged therefor are characteristic of the present attitude toward medical science in Germany.

One more item should be reported. The national führer of pharmacists has introduced a uniform escutcheon for all Ger-

man pharmacists. It is an old Germanic runic device. It bears a heraldic letter A (for apotheker) in red and a so-called manes-rune in white at the intersection of the left side-bar with the fess. The manes-rune is intended to be a symbolic representation of strength, health and life. The new emblem of the pharmacists has been registered at the national patent office. It may be displayed by any proprietor of a public pharmacy who belongs to the German Pharmacists' Association. The new escutcheon will at the same time do away with the use of the varied signs, the serpent and the cup, for example, as well as the use of the older pharmacists' escutcheon, which was a reverse of that of the Red Cross; namely, a white cross on a red field. The latter happens to be the coat of arms of Switzerland and from January 1, 1937, it will enjoy legal protection as such. This means that it must disappear from German apothecary shops, although till now it has been extensively used as a distinguishing mark of the German pharmacists.

## NETHERLANDS

(From Our Regular Correspondent)

Jan. 8, 1937.

### Habitual Alimentation

Drs. Banning and Den Hartog have submitted to the health organization of the League of Nations a study of present-day alimentary habits in the different provinces of the Netherlands. In the last few years the amount of fats consumed in the Netherlands has been on the increase. It cannot be said that this increase has taken place at the expense of the carbohydrates and/or the proteins, for the balance between these two elements has been well enough maintained. This increased consumption of fat has resulted in a notable, even perhaps an excessive, increase in caloric values. The increase in fats may be ascribed to the fact that the last few years were more prosperous than the immediately preceding years. The amount of protein nutriment consumed appears to be quite sufficient: the proportion of animal proteins of a high caloric value is in any event considerable. In highly industrialized or stock-raising regions there is a much greater consumption of milk and butter than in regions where agriculture properly speaking is the population's principal means of sustenance, the province of Groningen, for example. In purely agricultural areas the need for fats is met by recourse to fat-containing foods other than dairy products; to bacon, for example. In Drente a much poorer region of small stock farms, a greater part of the necessary calories is obtained from the potato and from farinaceous foods. The huge quantities of legumes and fruits consumed in the little industrial town of Zaandam may be strikingly compared with the small amount of the same comestibles eaten by the country folk of Westzaan. The Zaandam people also consume a greater amount of sugar and of fancy goods. Any project for feeding the unemployed must take into account the accustomed alimentation of a given population. The inhabitants of industrial urban communities have acquired eating habits which differ to a degree from those of the rural population. The unemployed townsman feels and quite rightly that he should receive a different type of food supply than that which is suitable for his rural compatriot.

### Anti plague Vaccine

Dr. Otten, director of the Pasteur Institute at Bandoeng, is introducing a new type of his "Otten vaccine" against plague. The vaccine in use heretofore with favorable results has been prepared from the stock of "Tjiwidej" rats. This serum has, however, not been effective against buboes. Dr. Otten has found a new stock from which he obtains a vaccine composed of an antigen other than the "Tjiwidej" stock. This new vaccine is capable of preventing not only plague but tumefaction of the buboes as well. It will be placed in use during 1937.

stimulating treatment for the weakened muscles. For this purpose the sinusoidal-faradic current is advisable.

The azoospermia, according to the history, is undoubtedly testicular in character. The therapy of this condition is entirely experimental and it is impossible as yet to recommend the use of special extracts for this purpose. Both positive and negative results have been reported with preparations of the gonadotropic principle of pregnancy urine, such as antuitrin-S. There is no evidence that androstine-Ciba could be of any use for this purpose; the Council on Pharmacy and Chemistry reported this product to be practically devoid of potency (*THE JOURNAL*, June 20, 1936, p. 2150). Favorable results have been reported with the use of a gonadotropic product from the pituitary itself; but even when azoospermia can be corrected the resultant spermia may be abnormal and lead to abnormal products of conception (Moench, G. L.: A Consideration of Some Aspects of Sterility, *Ann. J. Obst. & Gynec.* 32:406 [Sept.] 1936).

#### TAPEWORM INFESTATION DURING PREGNANCY

*To the Editor:*—Please advise me as to the treatment of tapeworm in a pregnant woman. A woman, aged 23, primipara, secundigravida, four months pregnant, has lost 3 pounds (1.4 Kg.) during the last month, although eating almost twice as much as normally, and during the previous months of her pregnancy she gained weight. The stools were of normal color although the bowels are very constipated and several times after enemas she has noticed broad white segments about one-fourth inch wide, varying in length from 3 to 4 inches. Without further examination I made a tentative diagnosis of tapeworm, most likely *Taenia saginata* or *Taenia solium*, as she gives no history of having eaten any fish all summer long. I requested her to bring in a stool for examination but as yet she has not done so; hence I cannot further substantiate my diagnosis. My problem is what treatment I should use to eradicate the worm if she continues to lose weight or becomes progressively anemic. Several of the textbooks that I have mention the fact that it should be treated conservatively during pregnancy. In *THE JOURNAL*, Sept. 1, 1934, in an article by Harold W. Brown entitled "Intestinal Parasitic Worms in the United States," it is stated that treatment with aspidium should be used with caution in pregnancy. He also mentions treatment with carbon tetrachloride but does not give pregnancy as a contraindication. Would this be the most acceptable form of treatment or would you recommend some other form? If printed, please omit name.

M.D., Minnesota.

**ANSWER.**—While aspidium and probably the other potent teniacides are contraindicated in pregnancy, pumpkin seed is not, as it is harmless in almost any dose. The seeds should, if possible, not be more than one month old. After the usual preparatory starvation the day before and the administration of a saline purgative the night preceding and again in the early morning, a very light breakfast may be taken. Two hours after this, one gives from 60 to 120 Gm. of pumpkin seed in three portions, two hours apart, the patient remaining in bed to avoid vomiting. The fresh seed should be beaten into a paste with water and finely powdered sugar, and water or milk added to make about 500 cc. If purgation does not occur within three hours after the last dose, a purgative—preferably castor oil—should be administered.

#### CONSTIPATION

*To the Editor:*—I should like to learn more of constipation and its management. I have the small book which you publish on cathartics but find this inadequate for the more obstinate cases. One patient is especially difficult, having been ill for a number of years and taken laxatives regularly during that time and has to take Empirin Compound frequently now because of pain. The liquid petrolatum preparations all cause so much distention that they cannot be used in his case. There seems to be a spastic condition in his colon and the bulk-providing laxatives are not effective. There is apparently no pathologic condition causing the constipation. It is due, I presume, to his inability to take exercise (his only exercise being walking a short distance each day), the long period of use of sedatives, and his highly nervous condition. None of these factors can be eliminated, and I should appreciate greatly any advice that you might be able to give, and any references you might give in which I could gain further information. Please omit name.

M.D., California.

**ANSWER.**—From the description it is reasonable to suppose that the patient is suffering from a condition of colon spasm in which irritative cathartics of all kinds are likely to make the condition worse. There are two problems to be solved: (1) to unlock the spasm and (2) to remove the cause.

In the symptomatic relief of the spasm, the use of oil is particularly indicated. When liquid petrolatum taken by mouth is not satisfactory, the use of oil enemas at bedtime is likely to be required. These consist of the patient injecting into the rectum, the last thing at night after he has gone to bed, as much warm olive oil as he can retain overnight. This usually is a cupful, more or less. Such enemas might be repeated every evening for several days until all hard lumps are elim-

inated from the stools and liquid petrolatum taken by mouth maintains a softness of scybala. In cases in which this combination is not satisfactory, daily teaspoonful doses of castor oil taken first thing in the morning have produced good results. While the patient is suffering pain due to the spasm, the employment of analgesics is advisable; but morphine must not be given. It is decidedly contraindicated in such cases. Bulk-providing diet is not tolerated at this stage, and a smooth, residue-poor diet is demanded. As this regimen is constipating and colon spasm is, after all, a variety of constipation, it is necessary to abandon this phase of treatment as soon as possible after the spasm has been satisfactorily relieved.

The removal of the cause is more difficult as well as more important. There are some cases in which the colon spasm is due to stasis in the proximal colon, which, in turn, is often dependent on minor organic abnormalities such as a low cecum or periceal adhesions. In these cases, after the spasm has been unlocked, the use of mild saline catharsis coupled with the most bulk-producing diet that the patient can tolerate is likely to produce satisfactory results. Such a diet might include, for instance, the more delicate cellulose-containing vegetables, such as spinach, asparagus and cauliflower, and possibly bran. While such a diet is not tolerated during the presence of active colon spasm, it is a preventive of its recurrence when the spasm has been relieved.

Another cause of the spastic colon is, no doubt, intestinal allergy and this requires the use of the so-called elimination diets and possibly skin tests, by means of which one might be led to the discovery of the offending food or foods.

The psychoneurotic background accompanying any one of these states, which acts as a predisposing factor, also needs to be taken care of. This requires a personality study to discover the nature and cause of the patient's maladjustment and the prescribing, based on the results, of the proper hygiene for that individual.

#### ENDOCRINE DISTURBANCE

*To the Editor:*—A man, aged 33, a physician, was 5 feet 8 inches (173 cm.) tall and weighed between 185 and 190 pounds (about 85 Kg.) at puberty, which was fully established between the thirteenth and fourteenth years, and up until the age of 18. He appeared to be suffering from a pituitary dysfunction. During this period the breasts were quite large and the lower part of the abdomen and the hips and thighs were well padded with fat. At the age of 19 years there was a marked loss in weight of 50 or 60 pounds (about 25 Kg.) preceding the removal of a gallbladder full of stones. Since the cholecystectomy and the less in weight the patient, when clad, has appeared to be normal in body contour. He has attained a height of 5 feet 9½ inches (175.5 cm.) and has been averaging during the past ten years from 155 to 160 pounds (about 71 Kg.) in weight but at times has weighed 175 pounds (79 Kg.). The tendency, however, at present and during the intervening years has been to deposit fat in the parts of the body already mentioned. The pelvis, though less wide than the shoulders, strongly suggests the female type. The genitalia are of average size and the sexual urge is normal. The basal metabolic rate for the past six or seven years has been low, minus 15 to minus 20, and the pulse from 60 to 64. The patient's chief complaint regarding this condition is that of embarrassment at the time of bathing and showering. Kindly advise the course of treatment I should follow in the case. Are there any undesirable effects that may follow the administration of antuitrin in this patient? If you should advise its use, please indicate the method of administration and its frequency. If published, please omit name and address.

M.D., Pennsylvania.

**ANSWER.**—It is difficult to say with certainty whether the patient represents an organic abnormality or simply a physiologic disturbance. Certainly the description does not suggest the diagnosis of Frölich's syndrome. Suggestions for treatment are difficult because of our inadequate knowledge of the underlying causes for such conditions. If we were certain that the cause is a deficiency of the gonadotropic factor of the anterior lobe of the pituitary we could recommend the use of one of the commercial products now available. The respondent mentions "antuitrin" as a possible form of treatment. Presumably he refers to "antuitrin-S," a substance prepared from the urine of pregnant women which probably is formed by the chorionic villi and therefore is not of pituitary origin. Its action, however, is similar to the luteinizing fraction of the anterior lobe, and it has been given wider clinical use than any of the hormones obtained from pituitary tissue. Insufficient time has elapsed to say with certainty that no harm can result from its use, but harmful effects are unlikely. The size of the patient's prostate should be observed, and if a significant increase occurs the injections should be stopped. Whether the injections will produce any improvement is equally problematic. A suggested dosage would be 2 cc. (200 units) subcutaneously two or three times a week for from four to six weeks. The suggestion is made that some such cases improve with the use of thyroid. Sufficient should be given to maintain the basal metabolic rate between zero and minus ten.

## Deaths

**Frank Smithies** ☉ Chicago; Chairman of the Section on Gastro-Enterology and Proctology of the American Medical Association, 1919-1920, member of the House of Delegates, 1927-1930, and in 1930 appointed a member of the Council on Scientific Assembly for five years, died, February 9, in the Augustana Hospital, of a cerebral hemorrhage, aged 56. Dr. Smithies was born in Elland, Yorkshire, England, Dec. 21, 1880. He received the medical degree from the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1904, and later studied abroad. He had been assistant in the clinical laboratory, instructor in medicine and demonstrator in clinical medicine at his alma mater, assistant in medicine at Rush Medical College, Chicago, assistant in pathology at the University of Berlin, and attending physician to the University of Michigan Hospital. From 1910 to 1913 he was in charge of the gastro-enterologic laboratory and an assistant in one of the sections on medicine at the Mayo Clinic, Rochester, Minn. He was appointed gastro-enterologist in the Augustana Hospital, Chicago, in 1913, and attending physician in 1922. He became associate professor of medicine at University of Illinois College of Medicine in 1917 and professor of medicine in 1922. Dr. Smithies was a fellow and past president of the American College of Physicians and the American Therapeutic Society; member and past president of the American Gastro-Enterological Association; formerly secretary general of the American Congress on Internal Medicine, and past president of the American Society of Tropical Medicine. He was formerly physician in chief and head of the department of medicine at St. Elizabeth's Hospital, attending physician at the Henrotin Hospital, chief of clinic in digestive diseases at the Municipal Tuberculosis Sanitarium and consulting physician to the Chicago, Milwaukee, St. Paul and Pacific Railroad. During the World War he was consultant in medicine in the U. S. Public Health and Marine Hospital Service, Port of Chicago; secretary and consulting internist, Medical Advisory Board 3B, Chicago, and member of the Illinois State Board of Advisers in Administration of Draft. In 1930 he was appointed a foreign member of the *Société médicale des hôpitaux de Paris* and in 1933 was awarded the cross of the French Legion of Honor. Dr. Smithies was the author of "Cancer of the Stomach" and of numerous articles and was editor in chief of the *American Journal of Digestive Diseases and Nutrition* and on the advisory board of the *American Journal of Tropical Medicine*.

**John Francis Hagerty** ☉ Newark, N. J.; University of the City of New York Medical Department, 1892; member of the House of Delegates of the American Medical Association in 1926 and 1927 and from 1930 to 1936; past president of the Medical Society of New Jersey and the Essex County Medical Society; fellow of the American College of Surgeons; served during the World War; for many years medical director and attending surgeon to St. Michael's Hospital; attending surgeon to the Hospital and Home for Crippled Children; consulting surgeon to St. Peter's General Hospital, New Brunswick, St. Vincent's Hospital, Montclair, Presbyterian Hospital, Newark, and St. Mary's Hospital, Orange; in 1930 was awarded an honorary doctor of laws from Seton College, South Orange; was president of the High Point Park Commission, 1925-1936; aged 67; died, February 1, of pneumonia.

**Anexamander M. Hayden** ☉ Evansville, Ind.; Starling Medical College, Columbus, Ohio, 1875; member of the House of Delegates of the American Medical Association, 1906 and 1908; past president of the Ohio Valley Medical Association and the Vanderburgh County Medical Society, and vice president of the Indiana State Medical Association; fellow of the American College of Surgeons; member of the Medical Service Corps during the World War; for eight years president of the city board of health; for many years chief of staff of St. Mary's Hospital; formerly owner of a hospital bearing his name; aged 84; died, February 9, in the Methodist Hospital, Indianapolis, of arteriosclerosis.

**Arthur George Bennett** ☉ Buffalo; University of Buffalo School of Medicine, 1891; member of the House of Delegates of the American Medical Association in 1926; professor of ophthalmology, emeritus, at his alma mater; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; consulting ophthalmologist to the Children's, Deaconess, Lafayette General, Buffalo General and Columbus hospitals, Buffalo, and the J. N. Adam Memorial Hospital, Perrysburg; on the staff of the Craig Colony, Sonyea; aged 75; died, Dec. 28, 1936, of carcinoma of the lung.

**Orville O. Witherbee** ☉ Los Angeles; Northwestern University Medical School, Chicago, 1893; a founder and fellow of the American College of Surgeons; past president of the Los Angeles County Medical Society and the Los Angeles Clinical and Pathological Society; formerly professor of surgery and clinical surgery at the Medical Department of the University of Southern California; on the staff of the Los Angeles County Hospital; aged 72; died, Dec. 24, 1936.

**Rollin Otis Crosier**, Johnson City, N. Y.; University of Buffalo School of Medicine, 1900; member of the Medical Society of the State of New York and the Associated Anesthetists of the United States and Canada; health officer of Johnson City and school physician; on the staff of the Charles S. Wilson Memorial Hospital; aged 59; died, Dec. 17, 1936, of cerebral hemorrhage.

**Alfred H. Easterling**, Athens, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1897; member of the State Medical Association of Texas; president and formerly secretary of the Henderson County Medical Society; for many years member and secretary of the school board; formerly county health officer; aged 71; died, Dec. 29, 1936, of pneumonia.

**Walker Bourne Gossett**, Lexington, Ky.; Louisville Medical College, 1896; member of the Kentucky State Medical Association; at one time instructor in obstetrics at his alma mater; formerly on the staff of the Western State Hospital, Hopkinsville; aged 63; on the staff of the Eastern State Hospital, where he died, Dec. 27, 1936, of coronary occlusion.

**George Allen Grinde** ☉ Cumberland, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; founder of the Island City Hospital, now known as the Cumberland Hospital, of which he was part owner and one of the physicians in charge; aged 56; died, Dec. 13, 1936, of chronic nephritis and hypertension.

**George H. T. Sparling**, Grand Coulee, Wash.; University of Oregon Medical School, Portland, 1890; member of the Washington State Medical Association; at one time coroner and health officer of King County; formerly health officer of Clark County; health officer of Grand Coulee dam; aged 67; died, Dec. 26, 1936, of pneumonia.

**Caroline Sandford Finley** ☉ New York; Cornell University Medical College, New York, 1901; was decorated by both the French and British governments for bravery during the World War; served the New York Infirmary for Women and Children in various capacities; aged 61; died, Dec. 28, 1936, of heart disease.

**William Waddell Skinner** ☉ Geneva, N. Y.; University of Buffalo School of Medicine, 1887; past president of the Ontario County Medical Society; on the staffs of the Willard (N. Y.) State Hospital and the Geneva General Hospital; aged 76; died, Dec. 28, 1936, of cerebral thrombosis and acute suppurative otitis media.

**Charles David Weaver** ☉ Twin Falls, Idaho; Colorado School of Medicine, Boulder, 1897; president of the South Side Medical Society; city and county health officer; served during the World War; on the staff of the Twin Falls County General Hospital; aged 68; died, Dec. 22, 1936, of a streptococcal infection.

**Ralph Douglas Porch**, Sylacauga, Ala.; University of Louisville (Ky.) Medical Department, 1907; member of the Medical Association of Alabama; formerly secretary of the Talladega County Medical Society; on the staff of the Sylacauga Infirmary; aged 53; died, Dec. 27, 1936, at a hospital in Chicago.

**George Lewis Wetzel**, Union Mills, Md.; Southern Homeopathic Medical College, Baltimore, 1906; member of the Medical and Chirurgical Faculty of Maryland; member of the county board of health and board of education; aged 50; died, Dec. 22, 1936, in the Hanover (Pa.) General Hospital, of cardiorenal disease.

**Jay Harvey Durkee**, Jacksonville, Fla.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; at one time secretary of the Fourth District of the Florida Board of Medical Examiners; for many years surgeon for the Southern Railway; aged 66; died, Dec. 29, 1936.

**Arthur Jacques Melchior Schneidenbach**, Leonia, N. J.; Maryland Medical College, Baltimore, 1901; veteran of the Spanish-American War; member of the board of health of New York City, 1905-1918; aged 60; on the staff of the Hackensack (N. J.) Hospital, where he died, Dec. 12, 1936, of acute ileus.

**Harry Clinton Crocker**, Providence, R. I.; Boston University School of Medicine, 1894; formerly member of the

Another possible source of the attack might lie in the sudden onset of an abnormal cardiac rhythm. A paroxysmal auricular tachycardia or fibrillation might produce a similar picture. As a rule, however, the arrhythmia can be definitely recognized if it persists or the symptoms rapidly disappear when the rhythm returns to normal.

Abnormal cardiac rhythm is not infrequently the sequel of coronary occlusion, so, all things considered, the diagnosis of coronary occlusion is the safest one to make in this instance.

#### OPHTHALMOPLAGIC MIGRAINE

*To the Editor:*—A strong, healthy man, now aged 23, has had three attacks of diplopia, the first when 15 years of age. The attacks all commence with a severe headache at the vertex, which lasts only a day or two, followed in twenty-four hours with diplopia, the muscle involved being always the right internal rectus, and there is no obvious squint. Diplopia in the first attack lasted eight weeks, in the second ten weeks, and in the present so far twelve weeks. His general health at present and in between the previous attacks has been perfect. There is no other abnormal neurologic change. The basal metabolic rate and the cerebrospinal fluid Wassermann reaction are negative. The fields of vision are normal and the skull roentgenogram is normal. Disseminated sclerosis seems to be ruled out by the headache. Can this be a leaking aneurysm? Please omit name.

M.D., England.

**ANSWER.**—The clinical description sounds like that of a true ophthalmoplegic migraine, a clinical entity that has been well known since 1877. There is the first stage of pain, which in this case is a vertex headache, followed immediately by the ocular paralysis of one branch of the third nerve. This phase may disappear in from one to six months or it may become permanent. Almost nothing has been added to our knowledge of the subject since the description that appeared on page 712 of "The Eye and the Nervous System," by Posey and Spiller.

#### BULIMIA—INSATIABLE APPETITE

*To the Editor:*—A white woman, aged 34, complains of insatiable hunger. This condition has existed for a period of two years. Prior to the onset of this condition, she had had an appendectomy and a right oophorectomy. Following this she first noticed constipation, and shortly afterward the insatiable hunger developed. This symptom became so pronounced at times that she has eaten as much as 6 quarts of cooked vegetables along with eighteen apples and thirty-eight graham crackers, in addition to cereal, bread and butter, milk and other food in one day. In January 1936, when I first saw her, there was no evidence of hyperthyroidism. The blood sugar was 89 mg. and the nonprotein nitrogen 35 mg. per hundred cubic centimeters, which ruled out a hyperinsulinism with a hypoglycemia. There were no intestinal parasites and not an excessive amount of undigested food in the stools. Gastric analysis showed a free hydrochloric acid of 72 per cent and total acidity 96 per cent. A barium sulfate meal showed no deformity of the stomach or duodenum. The stomach was of normal size and position and fairly normal tone and peristalsis. The colon was fairly normal. The transverse colon dipped down into the pelvis but the flexures are held up well in position. Other laboratory studies reveal a normal blood count, urinalysis negative and blood Wassermann reaction negative. Following a complete study the patient was placed on extract of belladonna one-sixth grain (0.01 Gm.) and a bland diet. Under this regimen she noted some improvement, but this continued for only about a month. In April 1936 the patient complained of marked constipation, tenesmus at stool and passing of large quantities of mucus. At this time attention was directed toward relieving the mucus by means of colonic irrigations. These have been continued over a period of four months. The mucus is relieved by the irrigations but the insatiable hunger persists. Attempt to control this by sedation and alkalis has been unsuccessful. I am at a loss to know what to attempt to do further for this patient and will be pleased to have any suggestions for future treatment. Please omit name.

M.D., Wisconsin.

**ANSWER.**—This patient obviously has what the Greeks called bulimia. A good review of the ancient literature on the subject can be found in an article by Baumann in Janus for September and October 1935. In making a diagnosis, one would want to know more of the mental status of the patient. Extreme forms of bulimia have been encountered in the psychopathic or the hysterical or the definitely insane. It would have been helpful to know if the patient is gaining rapidly in weight on the excessive intake of food. One would like to have one or more estimations of the basal metabolic rate, because bulimia is seen occasionally with an exophthalmic goiter so atypical as to be missed clinically. Perhaps the patient has a peculiar build or a male distribution of body hair or other signs of some disturbance in the functions of the ovary or of the pituitary gland. It is conceivable that some change in the pituitary gland secondary to the removal of the ovary has upset the hunger mechanism much as it appears to upset the thirst mechanism in diabetes insipidus. With the removal of the ovary was there much change in the menstruation suggesting a premature menopause? Because of the sequence of events, one would seek for the cause first in some disturbance in the

glands of internal secretion. In some cases of peptic ulcer with high acid such as this woman has, the patient is accused of eating too much when really her trouble is that she wants to eat every few hours. This woman's story is not that of ulcer. Diabetes has been ruled out and hyperinsulinism generally presents another type of syndrome. Further investigation for intestinal parasites should be made. The possible presence of protozoa, which are often extremely difficult to detect, should also be ruled out.

Certainly a story such as this is extremely uncommon and in making a diagnosis the physician can expect little help from the literature. One might try large doses of ovarian extract and as a long shot one might try the aminopyrine and solution of posterior pituitary that work such miracles in diabetes insipidus.

#### CODEINE ADDICTION—EFFECTS OF CODEINE ON MENTALITY

*To the Editor:*—1. Is codeine generally considered a habit-forming drug? 2. Would codeine over a period of one or two years in doses of 1 to 2 grains (from 0.0065 to 0.13 Gm.) given at bedtime for sleep in an old case of hypertension with a history of three attacks of hemiplegia be indicated or contraindicated, and would it in any way affect the mentality of such a patient (a woman, aged 78)? She had previously been given phenobarbital, but after a time that became ineffective and caused a so-called hangover the next day. The patient was under my continuous professional care for the past fifteen years and she recently died. The will, which was made about six months ago, is being contested, one of the points of those contesting the will being that codeine is a habit-forming drug, is contraindicated in hypertensive cases and so had affected her recovering, and the last will and testimony was influenced by it. Please omit name.

M.D., California.

**ANSWER.**—1. Codeine is less likely to produce habit than is morphine. Codeine addiction is rare and generally is easily broken.

2. It is not contraindicated. It has little or no effect on the heart or blood pressure. Its use may have been indicated in this case. The fact that it was effective for a year or more without increasing the dose speaks against habit—in the sense of morphine habit. We know of no acceptable evidence showing that codeine as used in this case influences mentality. It has been used habitually, from 0.065 to 0.2 Gm. (1 to 3 grains) each night for long periods, and its use discontinued with no more discomfort than follows the disuse of other sedatives such as the barbiturates.

#### HYPOPHYSECTOMY—FRÖHLICH'S SYNDROME

*To the Editor:*—A white boy, aged 12 years, has a definite Fröhlisch syndrome. This diagnosis has been confirmed by several of the most eminent clinicians in this part of the country. There is no evidence of a pituitary tumor. I would appreciate any suggestions you might have to offer as to therapy in this case. Please specify the type of glandular extract indicated, the amount to be given at each dose, the time interval between doses and for approximately how long such therapy should be continued. I know that treatment for this disorder at the present time is not definite, but I feel that the patient at least deserves the benefit of a trial of some of the newer glandular preparations. Please omit name.

M.D., Tennessee.

**ANSWER.**—At the present time it is certain that Fröhlisch's syndrome is a hypopituitarism associated with a hypofunction of either the testicles or the ovaries. The following experimental regimen is suggested: 1. Prephysin (said to contain the follicle-stimulating principle of the pituitary gland) injected hypodermically three times a week in 1 or 2 cc. doses. 2. Thyroid, 0.03 Gm., from two to three times daily for three months. 3. Minute amounts of dried posterior pituitary powder used as a snuff. This may be used twice daily. The patient may quickly learn to regulate this dosage to the minimum necessary amount and frequency. The foregoing should be continued for at least ten to twelve weeks. In the meantime the patient should frequently be reexamined to determine the development of any definite changes such as loss in weight decrease in amount of urine, and increased basal metabolic rate. Each individual case requires a careful checking period to determine the exact amount of medication that is necessary to effect changes.

#### PAIN IN CHRONIC LEG ULCER

*To the Editor:*—What can you suggest to relieve persistent local pain in a small chronic varicose leg ulcer in a barber, aged 63, which is slowly healing under rest and topical local applications? Do not publish my name.

M.D., Pennsylvania.

**ANSWER.**—Intractable pain in a slowly healing chronic leg ulcer may be due to (1) deficient arterial circulation, (2) inflammatory exudate around the ulcer with indurated elevated margins, (3) topical application of various irritating substances, which often do more harm than good, and (4) neuroma forma-

is overweight, it is necessarily an indication of thyroid deficiency and that thyroid should be taken for reducing." The company is also directed "to cease asserting that all modern physicians use the reducing ingredient in Marmola in the treatment of obesity and that this method of treatment in all such cases is supported by the opinion of science and medicine the world over, or that this treatment is the remedy indicated in and best suited for the great multitude of cases or in the average case, or for all over-weight persons." The company is further ordered "to cease and desist representing that it makes a full and complete disclosure of the properties and effects of Marmola or its ingredients, unless and until it does in fact make such disclosure, including the following: That desiccated thyroid is a powerful and dangerous drug or product when used internally for reducing purposes . . . that cases of abnormal excess fat caused by deficiency of the secretion of the thyroid gland are rare and exceptional; that physicians prescribe and recommend the use of thyroid for treating obesity only in cases of actual deficiency of thyroid gland secretion; that in cases of excess fat not caused by thyroid deficiency, thyroid is not usually indicated as a proper treatment, and its use in such cases is apt to be and frequently is harmful to the user's health."

Medical and scientific opinion, on which the Federal Trade Commission based its conclusions, was to the effect that only a small proportion of cases of overweight result from thyroid deficiency; that in many cases Marmola cannot be safely used and, in any case, should be taken only on the advice of a physician.

In 1930 the Raladam Company of Detroit, under the claim "This prescription is based on 22 years of experience . . . prepared for us in a world-famous medical laboratory," published the following formula for Marmola:

1 grain	Extract Bladderwrack
1/2 grain	Extract Phytolacca
1/4 grain	Extract Cascara Sagrada P. 87 Spec.
1/2 grain	Desiccated Thyroid
1/4 grain	Phenolphthalein
16/1000 min.	Oleoresin Ginger
	Po. Saccharum special
3 grains	Calcium Carbonate Precipitated
1/24 min.	Methyl Salicylate
1/24 min.	Oil Anise
1/24 min.	Oil Sassafras
	Talc Brown
	Ivory Black
	Aqua for Extracts
	Po. Burnt Umber
	Red Oxide of Iron
	Syrupus Simplex
	Lubricating Solution
	Aqua for Granulating
	Liquid Petroleum colorless"

The "world-famous medical laboratory" was not identified. Imagination fails when attempting to visualize Marmola given another twenty-two years of experience. The present action of the Federal Trade Commission closes another interesting chapter in the Marmola story, but not necessarily the finale.

### KELPODINE TABLETS

#### Seaweed Tablet Exploiters Fined

The United States Department of Agriculture at Washington, in a release for Jan. 17, 1937, states that it has concluded its case and imposed fines against John Lee Clarke and William J. A. Bailey of New York, proprietors of the Lee Kelpodine Company, Inc., manufacturers of "Kelpodine Tablets." According to the report, which was entitled "Seaweed Tablets No Good in 30 Different Ways," the tablets "were made of compressed seaweed or kelp and were fraudulently offered for the treatment of 32 specific diseases and 'other conditions.'" The diseases and conditions for which Kelpodine Tablets were offered include many of the most stubborn disorders known to medicine. The report further states: "The complete list for which these fakery recommended their seaweed products is as follows: pyorrhea, headache, indigestion, tuberculosis, cancer of the liver, glandular trouble, nervousness, dental caries, underweight, anemia, constipation, general weakness, melancholia, digestive disturbances, asthma, rickets, bone diseases, chlorosis, eczema, stomach disorders, nervous breakdown, migraine, high blood pressure, stomach ulcers, hay fever, liver congestion, subnormal growth, mental exhaustion, neurasthenia, rheumatism, arthritis, obesity and other conditions."

The Lee Kelpodine Company, Inc., utilized in its pamphlets and form letters the health fad nonsense so popular at the present time with the itinerant "nutrition" lecturer: that mineral deficiency in the daily diet is the most serious problem in modern medical treatment. Little has appeared in scientific literature on the use of kelp in medicine, but kelp as a source of iodine has been known to chemists for a great many years. Kelpodine was found not admissible to "Accepted Dental Remedies" in February 1935 by the American Dental Association.

William J. A. Bailey formerly traded as the Bailey Radium Laboratories, East Orange, N. J., and exploited a dangerous radioactive preparation known as "Radithor," to which was attributed the death of a prominent citizen of Pittsburgh, Eben M. Byers. The death of Mr. Byers focused nation-wide attention on the dangers of Radithor and forced Bailey to cease marketing that product.

## Correspondence

### USE OF JOURNAL BY LUNCHEON STUDY CLUB

*To the Editor:*—Perhaps this might be of interest to THE JOURNAL: Our hospital staff formed a luncheon club. We meet the same day each week at 12:30. The club is known as the A. M. A. Club. Three of the most interesting articles of THE JOURNAL are chosen by the chairman of our club. One of these articles is given to each man to digest and present a summary of the article. He is given five or six minutes to do this. The chairman of the club also in a five or six minute talk gives a review of the principal articles of THE JOURNAL. The result of this has met with favor in that every man feels that he is missing a great deal when he neglects reading his copy of THE JOURNAL. Especially do the men whose duty it is to give a digest of the articles get a great deal from the subject discussed.

I just pass this on to THE JOURNAL as a suggestion for other hospital groups so that our mouthpiece, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, might be reviewed.

W. A. McMILLAN, M.D., Charleston, W. Va.

### FERROUS SULFATE FOR WORMS

*To the Editor:*—In view of the difficulty sometimes found in getting rid of Trichuris trichiura infestation, the following note may be of interest: I purchased a small sheep-dog pup from a famous kennel and was distressed to find a week later that he was infested not only with Ascaris and hookworm but also with whipworm. I treated him with a standard preparation of tetrachlorethylene and completely eliminated the Ascaris and hookworm but found no reduction in the quantity of whipworm eggs, which averaged 8 or 10 to a low power field in simple smear preparations. These eggs were invariably present on repeated examinations over several weeks. The dog suffered from severe colitis, passing mucus and blood in loose stools, and was obviously anemic. Having at hand samples of a well known preparation of coated tablets of ferrous sulfate 3 grains (0.2 Gm.), I gave the dog, which weighed 10 pounds (4.5 Kg.) one tablet daily for a fortnight, and finally two tablets one day. The following day he passed a mass of whipworms and since then, nearly two years ago, I have never found a whipworm egg in his stool. Subsequently I read, in Ashmont's Kennel Diseases (Boston, Little, Brown & Co., 1924, pp. 333-334), "A remedy for worms (Ascaris) which acts well as a rule with puppies, is the sulfate of iron. This is not only quite a potent vermifuge but an admirable tonic." I have had no subsequent opportunity to test the anthelmintic effect of ferrous sulfate, but as an iron tonic is frequently indicated in treating infested patients, it would seem worth trial and observation, by others.

MARY PUTNAM, M.D., Rye, N. Y.

to be loosened, and it has an all metal plunger, which should extend its usefulness over a long period of time. To use this device, it is held in the right hand and the locking collar is turned to the right until it is fully extended. Then it is filled with water by withdrawing the piston, and the frozen syringe is then placed as far as it will go into the rubber collar, after which the locking collar is turned tightly to the right. Pressure is then applied and the frozen plunger is loosened.

#### TREATMENT OF ANEURYSM

To the Editor:—I have a patient with an aneurysm of the arch of the aorta. It is quite obvious on his chest wall. I have explained to him that it is not amenable to surgical treatment. I will appreciate it if you will inform me if there is any recent surgical procedure which will benefit him.

PHILIP S. JOSEPH, M.D., Alice, Texas.

ANSWER.—No, there is no recent surgical treatment of value for aneurysm of the arch of the aorta.

#### HYPERPYREXIA IN TREATMENT OF SYPHILIS

To the Editor:—In Queries and Minor Notes in THE JOURNAL, January 9, M.D., California, writes of hyperpyrexia in the treatment of a case of syphilis resulting in the death of his patient.

From my experience in the treatment of a large series of cases with physically induced elevation of systemic temperature, and from the data contained in this communication, I feel that it is necessary to call attention to the following facts:

1. A mouth temperature of 106 F. is extremely dangerous because, while in the grand average of cases the systemic temperature as measured by rectal thermometer may be within 1 degree F. elevation beyond the mouth temperature, it not infrequently happens in an individual case that the rectal temperature may be as high as 2 degrees F. above that indicated in the mouth. Mouth temperatures must be taken very carefully because of the cooling effect of liquids ingested by the patient and because of the cooling effect of the air passing in and out of the respiratory tract. In other words, this patient's temperature may have been 108 F. or even higher by rectum. One-fourth grain (0.016 Gm.) of morphine sulfate was administered hypodermically after the patient's mouth temperature had been elevated to 106 F. There is no notation of temperature during the next thirty-five minutes. An increase in the temperature following the administration of morphine is usually observed unless steps are taken to increase heat loss or to diminish the amount of heat applied. It is also of interest to note that the pulse rate, which at 10:45, when the mouth temperature was 104.4 F., was 140 beats per minute, at 11:10, when the mouth temperature had risen to 106 F., diminished to 104 beats per minute.

2. In the narration of the management of the case, reference is made to the fact that a technician was left in charge of the case at these temperatures. The communication states that "stimulation was applied as much as a technician could apply." In my opinion it is imperative that a physician who is specially trained in the administration of physically induced temperature elevation be continuously present during treatment and until the temperature is permitted to recede to below 104 F. or, better still, to below 103 F. (rectal temperature). This is a major procedure wherein the development of changes leading to death may occur within a few minutes. This makes it necessary to observe the systemic temperature at frequent intervals—at least every ten minutes or, preferably, continuously by means of the special registering instrument available for the purpose. This instrument as well as clinical thermometers must be frequently checked because so much reliance is placed on the absolute fact of the temperature observed. The physician in attendance should also be prepared to administer emergency measures to forestall a fatal termination. It is hardly just to the technician to expect him or her to be possessed of all the necessary medical background as well as the exact information so as to be able to act in such emergencies. Certainly it does not appear to be just to the patient.

If patients are to continue to receive treatment such as that described and under the circumstances mentioned, one may reasonably expect an increasing number of deaths due to the exceedingly high temperatures employed rather than to any special peculiarities in the reactions of the patient. A therapeutic procedure that is showing much promise in the treatment of important diseases may well come to be thrown into the discard because of the lack of care used in its administration.

WILLIAM BIEMAN, M.D., New York.

#### HEIGHT-WEIGHT-AGE FORMULA

To the Editor:—Relative to the question asked by a New York physician in THE JOURNAL, January 16, page 227, regarding determination of normal weight when only age and height are known, I had a formula given me several years ago by an assistant medical director of an insurance company that for all practical purposes conforms to the usual "standard weight" tables issued by insurance companies. This formula is as follows: Multiply the number of inches above 5 feet by  $\frac{5}{8}$  and add 110. This applies for adults from 18 or 20 to 35, and above 35 add 10 pounds. Thus for a person 25 years of age and 70 inches in height, 10 times  $\frac{5}{8}$  plus 110 equals 165 pounds. Above 35 the addition of 10 pounds, 175. I found this formula to be of practical benefit in many insurance examinations during the time I was engaged in the practice of medicine, and while it is true that no "normal weight" is known, it will perhaps serve the inquirer for practical purposes.

MILTON THARP, M.D., Nashville, Tenn.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

- ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Ed-  
519 Dexter Ave., Montgomery.
- ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.
- ARIZONA: Phoenix, April 6-7. Sec., Dr. J. H. Patterson, 826 Sec-  
Bldg., Phoenix.
- ARKANSAS: Medical (Regular). Little Rock, May 11-12. Sec. F.  
A. S. Buchanan, Prescott. Medical (Eclectic). Little Rock, May 1.  
Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.
- CALIFORNIA: Reciprocity. San Francisco, March 3. Sec., Dr. Chas.  
B. Pinkham, 420 State Office Bldg., Sacramento.
- COLORADO: Denver, April 6. Sec., Dr. Harvey W. Snyder, 422 Sec-  
Office Bldg., Denver.
- CONNECTICUT: Hartford, March 9-10. Endorsement, Hartford, March  
23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.
- DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware.  
Dr. Joseph S. McDaniel, Dover.
- DISTRICT OF COLUMBIA: Basic Science. Washington, June 23-24  
(probable dates). Medical. Washington, July 12-13. Sec., Commis-  
on Licensure, Dr. George C. Ruhland, 203 District Bldg., Wash-  
ington.

waukee.

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special  
Boards were published in THE JOURNAL, February 13, page 582.

### Kansas December Report

Dr. C. H. Ewing, secretary, Kansas State Board of Medical  
Registration and Examination, reports the written examination  
held at Topeka, Dec. 8-9, 1933. The examination covered 100  
subjects and included 100 questions. An average of 75 per  
cent was required to pass. Six candidates were examined.

positive reaction to the skin test. The method involves the measuring of the phagocytic power of the polymorphonuclear leukocytes in an opsonocytaphagic system. The absence of marked phagocytic activity of the polymorphonuclear leukocytes in a patient with a positive skin test is believed to indicate active infection due to *Brucella* organisms and a lack of immunity. The presence of marked phagocytic activity would indicate either a developing or an established immunity. If marked phagocytic activity and a positive skin test are demonstrated in a patient with fever, it is likely that the fever is due to some disease other than brucellosis. Keller, Pharris and Gaub (*THE JOURNAL*, Oct. 24, 1936, p. 1369) have reported favorably on the practicability of the opsonocytaphagic test. In interpreting any of the tests for brucellosis, due regard must be given to the clinical symptomatology. If repeated agglutination tests are negative and if the intradermal test is negative, it is quite unlikely that the patient has or has had brucellosis.

*Brucella melitensis* vaccine (abortus, suis and melitensis variety), N. N. R. appears to exert a favorable influence in most cases of brucellosis. The vaccine is available through the usual trade sources. The vaccine may be used for the skin test by diluting 0.1 cc. of the vaccine with 0.4 cc. of sterile physiologic solution of sodium chloride. The intradermal test is made with 0.1 cc. of the diluted suspension, producing a wheal about 5 mm. in diameter. Dr. Lee Foshay of the Department of Bacteriology, University of Cincinnati, has developed an antiabortus serum, which is apparently effective during the first three months of the disease. I. F. Huddleson of Michigan State College, East Lansing, Mich., has utilized a bacteria-free broth filtrate of *Brucella* organisms, known as "brucellin," in the therapy of brucellosis, with apparently good results. Transfusions with blood from persons who have made a satisfactory recovery from brucellosis may be of benefit.

Prickman and Popp (*Proc. Staff Meet., Mayo Clin.* 11:506 [Aug. 5] 1936) have reported favorable responses in refractory cases of brucellosis to artificial fever therapy.

#### CHRONIC SINUSITIS

*To the Editor:*—I have under my care a patient with chronic sinusitis, affecting particularly the antrums, of five years' duration. The patient has had repeated irrigations, with temporary relief. Now the question arises as to what procedure holds the best possible chance of permanent relief. I am anxious to know definitely whether breaking down the medial walls of the antrum to make permanent drainage openings is a wise procedure in this case, whether continued irrigations through a small opening only when absolutely necessary is better, or whether these sinuses should be left alone entirely. Please do not mention name.

M.D., New York.

*ANSWER:*—The treatment of chronic sinusitis is influenced by several factors. If the acute exacerbations are not increasing in frequency or severity, if severe headaches are not present, and the patient is in no great distress or incapacitated when he has an acute attack, it is often difficult to decide whether any operative procedure is indicated. If, on the other hand, symptoms and signs become more distressing, more frequent or even continuous, some operative procedure is needed. When it is the maxillary sinuses that are especially involved, the possibility of a dental origin of the infection must always be considered. It is advisable to have x-ray films made especially of the upper bicuspids and molars. It is the first and second molars and second bicuspids that lie in close proximity to the floor of the maxillary sinuses. A roentgenogram of the sinuses then would likewise be indicated in order to determine to what extent changes have occurred in the sinus, mucosa or bone. If there is suspicion of the presence of polypi, injection of some radiopaque substance should be done, and x-ray films made to see if there are any filling defects. If there are marked changes in the sinus mucosa and especially if polypoidal formation is present, irrigations of the sinuses will give only temporary relief or none at all. If considerable pus is present but no polyps, one of several operations may be performed, such as making a large opening into the antrum by way of the inferior meatus. This procedure followed by a number of irrigations may suffice. As a rule, if polypi are present irrigations are of no avail, and it is necessary to perform a radical operation. Perhaps the most commonly employed is the Luc-Caldwell. Here the antrum is entered through the canine fossa, a large opening made so that the whole antrum may be inspected, any polypi or diseased mucous membrane removed, and a large counter opening made into the nose by way of the inferior meatus either with or without formation of a flap of the mucous membrane. The buccal mucosa is closed with sutures after the antrum has been packed with gauze of one type or another,

removable through the nose. Some operators insert large rubber tubing instead of gauze. The more radical Denker operation may be employed when the pathologic changes in the antrum are more extensive.

#### TREATMENT OF EDEMA IN CIRRHOSIS OF LIVER

*To the Editor:*—I have a case of cirrhosis of the liver with general anasarca and ascites. The patient is an alcoholic addict. Tapping, April 1, recovered a gallon of clear yellow fluid which on standing twenty-four hours assumed a greenish tinge (probably bile). May 8, tapping recovered 2 gallons of the same fluid. May 27, tapping recovered 2 gallons. The urine, May 22, contained 0.27 per cent of albumin, hyaline casts, a few red blood cells and a few white blood cells. The specific gravity was 1.025. Bile was present occasionally. His elimination is about 1 quart of urine a day and five bowel movements (small in amount). There is little or no perspiration. The blood chemistry is nearly normal except for a slight increase of blood sugar. About five years ago he had glycosuria and all the symptoms of diabetes. This cleared up by keeping his rum away from him. I concluded that his glycosuria was a toxic condition from alcohol. He also has a myocarditis as shown by dyspnea, irregular feeble pulse and considerable drop in blood pressure since I treated him. He has been incapacitated for work since January 8. I tap him only when pressure symptoms cause increased dyspnea. I should like to reduce the general edema of his skin. Diuretics, so far as I can see, keep his kidneys working but do not reduce the general edema. In view of the almost normal kidney function (as shown by blood chemistry) I have not restricted his diet very much, as attempts along this line have caused delirium and extreme weakness. Hot packs weaken him too much. In view of all this, would you suggest the use of salyrgan? I am a bit afraid to use it because of the heavy albumin. I did try half an ampule and he passed very little urine in twenty-four hours. Now with a little less albumin than formerly would you use the mercurials to promote diuresis? I am afraid of them in this case. How about you? How would you attempt to reduce the edema? Of course he had a few running sores where edema has been too much for his skin. Are any of the master clinicians using Southey tubes for the massive edema in these cases? I have never seen one used in my experience.

HENRY E. B. MEYER, M.D., Brooklyn.

*ANSWER:*—On theoretical consideration, the mercurial diuretics are used guardedly when there is a suspicion of renal damage. Actually they are used with excellent results in many cases of severe renal disease. In this case there seems to be no contraindication to the use of these agents. It has been found that the acid-base salts for three or four days preceding the mercurials greatly enhance their effect. Ammonium nitrate or ammonium chloride, in doses of from 6 to 8 Gm. a day, are recommended. A brisk saline purge on the second day following the mercurial is believed to reduce the possibility of mercurial enteritis. The use of Southey tubes or incision of the skin has been largely abandoned. The removal of edema in this case is certainly to be desired and it is possible that the abdominal taps may be less frequently required. If the mercurial diuretic fails to produce the desired result it is not wise to repeat it until an interval of one or two weeks has passed by. With the majority of mercurials that are on the market, a dose of 2 cc. is considered the optimum.

#### TREATMENT OF AZOOSPERMIA

*To the Editor:*—For the past three months I have been treating a man of 41 for premature ejaculation and aspermia (proved on two tests). My therapy consisted of antuitrin-S injections (1.5 cc. three times a week) and later a preparation called Androstine (Giba). The patient has a small penis and small testicles and has been suffering from grand mal attacks since the age of 18. Aside from the foregoing he is absolutely negative to physical examination and history. He becomes easily aroused sexually and ejaculates even while dancing with a female partner. Could you advise further investigation or methods of therapy? Are there any new forms of male sex hormone available? Please omit name.

M.D., New York.

*ANSWER:*—The inquirer probably means azoospermia, as aspermia means no ejaculation at all during coitus and therefore it is impossible to have both aspermia and premature ejaculation. The most frequent cause for premature ejaculation is excessive ungratified sexual excitement, such as spooning, indulged in either before marriage or thereafter. In these cases the prostate and prostatic urethra are so congested that the reflex act of ejaculation takes place with the beginning of coitus. This condition can be verified only by examining the prostate by rectum and the prostatic urethra by cysto-urethroscopy. The treatment is sexual rest and getting rid of the local congestions by prostatic massage and instillations of weak silver nitrate solutions (from 1:3,000 to 1:500) into the prostatic urethra with the Bangs sound syringe. Generally seven or eight such treatments get the parts normal. Some patients are well as soon as the local congestions are removed, and some, especially if the condition has lasted a long while, need

If neither form of treatment produces improvement, the patient should be reassured that after all the condition is more damaging to the ego than it is damaging to health and that bathing in private is still practiced by a few more sensitive individuals. The normality of the genitalia and "sexual urge" should more than compensate for abnormal fat deposits.

#### ANGIONEUROTIC EDEMA AFTER SEXUAL INTERCOURSE

*To the Editor:*—A married man, aged 40, has noticed in the past year that, following intercourse, a moderate, symmetrical swelling of both hands appears. This swelling is noninflammatory, pits on pressure and is not painful. It persists from five to seven days. Edema is absent in other dependent parts of the body. Points in his past history include a gonorrheal infection ten years ago, more recently a peptic ulcer, which responded well to treatment, and occasional exacerbations of a chronic sinus infection. It seemed to me at first that this was evidence of cardiac insufficiency, though physical examination of the heart did not support this contention. Moreover, the edema persisted in spite of complete digitalization. There are no significant phenomena manifest in the head and neck. The blood pressure is 118 systolic, 72 diastolic, the lungs are clear, and the abdomen, external genitalia, prostate, other extremities, skin and reflexes are normal. The urine is normal, the hemoglobin is 96 per cent, erythrocytes are 4,900,000, leukocytes number 7,200, the differential count is normal, and the Wassermann and Kahn reactions are negative. Please omit name if published. M.D., Ohio.

**ANSWER.**—The brief history given suggests the possibility of angioneurotic edema as a cause for the swellings. No mention is made as to whether the penis is involved in these swellings. The treatment consists in a search for the causes of the condition. The many factors to be considered are:

1. Emotional disturbances may be either a primary cause of angioneurotic edema or may act as a predisposing cause in the presence of other etiologic factors.

2. Autosensitization to semen has been reported by W. L. Cooper (*J. Pediat.* 7:179 [Aug.] 1935). Such sensitization seems improbable in spite of this one report.

3. Asthma and dermatitis occurring during intercourse or apparently related to it have been traced by Vaughan and Fawkes (*THE JOURNAL*, Sept. 21, 1935, p. 955), to specific sensitization to such substances as orris root, silk, rubber and contraceptives. Rattner and Pusey (*THE JOURNAL*, Dec. 3, 1934, p. 1934), reported an interesting case of dermatitis due to perfume. A search of such contact possibilities that may occur during cohabitation (flaxseed in hair setting materials, perfumes), which may be used by either person, may prove helpful. In the Vaughan and Fawkes article, physical allergy due to effort and heat during coitus is mentioned as a possible factor for the attack. This, however, may be ruled out if other forms of exertion fail to produce the swellings.

4. A focus of infection has been considered as a cause for angioneurotic edema. The history of a gonorrheal infection suggests the possibility of a chronic prostatitis. Examination for this possibility and suitable treatment, if present, should be one of the first steps to be made in this case.

#### OBSCUR PROSTATIC DISORDER

*To the Editor:*—This question has to do with a prostatic disorder of apparently confirmed tuberculous origin. The patient has frequency, urgency and nocturia, but no hemorrhage in the urine has been observed. There is a history of tuberculosis of the chest fifty years ago. He is now 78 years of age. His blood pressure is 140 systolic, 80 diastolic, temperature 98 F., pulse 76, respiration 18, weight 140 pounds (63.5 Kg.). His chest is negative on physical and x-ray examination. The prostate is slightly nodular and slightly enlarged, the middle lobe more so than the lateral lobes. X-ray examination of the pelvis shows no metastatic involvement. The prostatic smear is negative. What is the best supportive treatment he can be given? I have advised against surgery. The blood Wassermann and Kahn reactions are negative. M.D., Pennsylvania.

**ANSWER.**—Active tuberculosis of the prostate gland without tuberculosis elsewhere in the genito-urinary tract would be exceedingly rare. If the condition is tuberculous, the existence of coincident tuberculosis in the kidneys or bladder would be necessary to cause the symptoms described. There are many other lesions in the urinary tract that might cause similar symptoms, such as tumor or diverticulum in the bladder, and any of the various forms of pyelonephritis and cystitis. Nodular changes in the prostate gland with enlargement may accompany any form of prostatic disorder.

The correspondent does not state whether the patient has any residual urine in the bladder. The bladder is sometimes found to be obstructed without symptoms of urinary difficulty. If there is obstruction caused by the prostate gland it would probably be due to hyperplasia, with or without secondary infection, rather than to tuberculosis. Chronic prostatitis, with or without

stones, may be present even though the first prostatic smear is negative and may also cause the clinical data described. The possibility of carcinoma is not excluded, even though the roentgenograms show no evidence of metastasis. If cystoscopic examination reveals obstructing prostatic tissue, transurethral resection may be indicated.

In order to make an exact diagnosis it would be necessary to make a careful study of the urine, including gram stains, stains for the bacillus of tuberculosis and cultures of the urine, and possibly inoculation of guinea-pigs. In addition, cystoscopy as well as roentgenographic and urographic studies of the urinary tract are essential.

#### VENEREAL VEGETATIONS

*To the Editor:*—For the past ten weeks I have had under treatment a 20 year old youth with venereal vegetations. He is a delivery clerk for a grocery. His general health has always been good. The foreskin is not long or tight; in fact, the foreskin is shorter than the average. He has never had a gonococcal infection. Before he came to me, another physician had removed the vegetations several times with nitric acid, but they returned each time. I have repeatedly removed the growths with trichloroacetic acid and have used various dusting powders, principally thymol iodide. The vegetations come off nicely in a few days, without giving more than a trifle of discomfort, but in about ten days they return. This has occurred repeatedly; consequently the young man is much discouraged. Can you suggest any effective treatment? Kindly omit name and address. M.D., Kansas.

**ANSWER.**—These vegetations should be removed by fulguration with the high frequency current. Even though the foreskin is neither long nor tight, secretions from under it may be the cause of the recurrences. Circumcision may prevent further recurrence.

#### CORONARY OCCLUSION

*To the Editor:*—A white man, aged 64, was suddenly seized with an attack consisting of dyspnea, weakness, dizziness and extreme anxiety. He was cyanotic and had a weak, thready pulse extremely variable in volume. There was no pain in his chest, but he did express a sensation of tightness. He has mild untreated diabetes and the blood pressure is 220 systolic, 110 diastolic. He also states that he has had trouble a great deal from time to time with a cough of the hacking type, with an occasional production of thick mucus, which he attributes to chronic bronchitis. There is also a history of some degree of albuminuria. He is a heavy smoker, using from four to six cigars a day, with some additional pipe smoking. Previous to his attack his pulse rate was about 62 beats a minute. His heart is enlarged to the left about 4 cm. beyond the nipple line and there is a slight enlargement to the right. There are no murmurs, and the tones are those which would be expected in one with a hypertension. Examination of the chest reveals a few moist râles at the bases of both lungs. There is some pitting edema of the ankles. Treatment consisted of absolute rest in bed and morphine sulfate one-eighth grain (0.008 Gm.) every four hours for relief of dyspnea. During the first thirty-six hours no relief was noted. There was a drop in the blood pressure to 162/100, but the pulse remained weak and rapid. Partial coronary occlusion was suspected in spite of the absence of pain, but the patient stated that he had previous attacks of this type even several years earlier, which were diagnosed as asthmatic. He was given 3 minims (0.18 cc.) of epinephrine hydrochloride 1:1,000 the third day, but instead of being relieved he was seized with a sharp pain in the region of the right pectoralis muscle, and the dyspnea was greatly increased; in fact, the whole syndrome was greatly accentuated and remained so for about thirty minutes, when he was allowed to inhale amyl nitrite, with almost immediate relief from his suffering. Following this he was put on theophylline with ethylene diamine, 1½ grains (0.08 Gm.) six times daily, and continued to improve until, five weeks later, he refused to remain in bed any longer, at which time he began to return to look after his business, spending a few hours each day at his office. While he is not quite as well as he was while in bed, he states that he feels much better than he had previous to his attack. Would a diagnosis of partial coronary occlusion seem logical? What else might cause the same syndrome? Please omit name. M.D., Minnesota.

**ANSWER.**—A diagnosis of coronary occlusion not only seems logical in this case but is the most likely condition that would produce this picture. The setting for a coronary occlusion is an excellent one. A diabetic patient with hypertensive heart disease and a mild cardiac insufficiency is an excellent subject for such an accident. The resulting pain is not always severe and the sensation of tightness in the chest is quite as good a diagnostic point as pain. All the other symptoms mentioned form an almost perfect picture of coronary occlusion. If, in addition to the symptoms mentioned, there could be added an elevation of temperature, an elevation of the leukocyte count and a pericardial friction rub, nothing would be lacking.

The reproduction of the syndrome after the administration of epinephrine is confirmatory evidence. This drug has been used as a diagnostic agent to produce attacks of angina pectoris. Its use in this way has been abandoned because of the danger connected with it.

**Nogle røntgenbiologiske Forsøg, med et transplantabelt Muscarcinom og et transplantabelt Muselymfosarkom som biologiske Objecter.** Af Mogens Thrane. (Mit deutscher Zusammenfassung). Paper. Pp. 118, with 9 illustrations. Copenhagen: NYT Nordisk Forlag: Arnold Busck, 1935.

This monograph represents experimental work done by the author for his doctor's degree. It is of special interest to cancer students and those physicians who use radiation as a method of treatment in cancer. The author uses mice and has confined his work to mouse carcinoma and mouse lymphosarcoma. He first attempted to determine the lethal dose in each tumor in vitro and in doing so established the fact that the lethal dose is the same whether a single massive treatment is given or whether the dosage is divided and protracted as in Coutard's technic. He then gives up to ten times the lethal dose to the tumor and finds that on implantation of the irradiated tumor it still has the power of growth after twenty-four and forty-eight hours. Experiments were then conducted on the possibility of increasing the resistance of the host toward new growths by total irradiation of the animal. The conclusions reached are to the effect that irradiation does not, in itself, lead to increase of resistance on the part of the host. The literature is reviewed and a long bibliography is attached. Interested students should consult the original. Since many are not familiar with Danish, a summary in German is attached.

**Health Facts for College Students: A Text-Book of Individual and Community Health.** By Maude Lee Etheredge, M.D., Dr.P.H., Professor of Hygiene and Medical Advisor for Women, University of Illinois. With a foreword by Ray Lyman Wilbur, M.D. Second edition. Cloth. Price, \$2. Pp. 365, with 61 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This contains certain revisions and additions which represent distinctive improvements over the first edition, valuable though that was. The author has had extensive experience in the teaching of hygiene to women students of the University of Illinois and through this book is offering to students and other teachers of hygiene the advantage of her rich and successful experience in this work. She uses a style that makes for relatively easy reading and tends to hold the interest surprisingly well in a book which in general make up conforms to the traditional textbook. The subject of individual and community health is comprehensively—possibly too comprehensively—covered for a small book. The important points are presented without a confusing mass of detail; the hosts of "dos" and "don'ts" of hygiene which college students so strongly resent have been largely omitted. The information presented is scientifically sound. For the purpose for which it is intended, that is, the presentation of health facts to college students, this book can be well recommended.

**Otosclerosis: A Résumé of the Literature—1928-1935. Volume III.** Edited by Arthur B. Duel, M.D., and Edmund F. Fowler, M.D. Issued by the Central Bureau of Research of the American Otological Society, Inc. Cloth. Price, \$3.50. Pp. 180. Saint Louis, Missouri: Annals Publishing Company, 1936.

This volume, which represents the third in a series on otosclerosis, presents a review of the literature from 1928 to 1935 inclusive. The American Otological Society, through its Central Bureau of Research, has done remarkable work on the subject of otosclerosis. The first two volumes were even more extensive than the present one. This volume has the subjects divided into fifteen chapters, including those on heredity, embryology, regression, bone pathology, endocrinology, metabolism, psychology and treatment. In the second section there is an index of the literature according to authors and an annotated bibliography. The subject of otosclerosis is so complicated, the theories regarding its pathogenesis so numerous, and the matter of treatment so nearly nonexistent that any information is highly welcome. This publication represents great labor, is most authoritative, and should prove as important and instructive as the two preceding volumes.

**Straalogenetik og klinisk Røntgenvirksomhed.** Af L. Østergaard Christensen. Paper. Pp. 177, with 3 illustrations. Aalborg: Knud Engsløgs Boghandel, 1935.

Shortly after the introduction of x-rays into clinical practice, it was observed that the cells of reproduction were especially sensitive to irradiation. This has led some observers to feel that children born from cells damaged by irradiation would show various developmental defects. This is the problem that

the author has been working on experimentally. His work was done on white mice. They were subjected to small doses of x-rays up to doses of 800 roentgens, after it had been determined that the sterilization dose was 1,000 roentgens. Some of the animals were subjected to direct irradiation, while some had only scattered irradiation, such as obtains when the animal is in the treatment cubicle but is not in the radiation beam. The author was unable to demonstrate any gene or chromatin effects in his material, but he did find profound effects on growth and longevity of the offspring. As a result of his work he concludes by saying that certain rules and regulations are in order in clinical radiology: 1. Therapeutic doses should not be applied to the organs of reproduction unless one is sure that a permanent sterilization is produced. 2. Radiation associated with diagnostic processes in the neighborhood of the reproductive organs should be reduced to a minimum. 3. X-ray technicians should avoid direct and secondary irradiation as much as possible. This piece of work should be of special interest to radiologists and students of morphology.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts: Prescribing Over the Radio; Prejudice of Members of Board in Revocation Proceedings.**—A complaint was filed with the Kansas state medical board April 28, 1930, seeking the revocation of Dr. John R. Brinkley's license to practice medicine in that state. The complaint contained eleven specific charges of fraud, immorality and unprofessional conduct. One charge was that Brinkley performed a "compound operation" on patients for the purpose of curing impotence, high blood pressure, epilepsy, dementia praecox, and diseases of the prostate gland and kidneys, and that the operation was of no value to patients. Another charge was that Brinkley gave talks over the radio—

for the purpose of enticing patients to his hospital and to induce persons to purchase medicines; that he diagnoses and prescribes for patients over the radio; that he gives prescriptions by numbers which have to be filled by and purchased at certain drug stores, from which he obtains a commission; . . . that such diagnosing and prescribing by radio are necessarily inaccurate and dangerous, carrying too great a hazard of error in misinterpretation of symptoms, inaccuracy or patients' statements of the location and character of complaints, the risk of misunderstanding the respondent's directions and confusion of numbers given of prescriptions, and lacking entirely in the information to be gained by the usual ordinary routine physical and laboratory examination of the patients, without doing which respondent is grossly negligent.

Brinkley was given notice of the charges and a hearing was held July 15, 1930. The hearing, with some adjournments, lasted until September 16 and included a session at which Brinkley performed the "compound operation" in the presence of the board. On Sept. 17, 1930, the board revoked Brinkley's license and on Dec. 30, 1931, he instituted proceedings in the United States district court, district of Kansas, to set aside the revocation order on the ground that it invaded rights guaranteed to him by the federal constitution. The district court, after a long trial, dismissed the action, July 15, 1935, and Brinkley appealed to the United States circuit court of appeals, tenth circuit.

Does this record disclose, asked the court, no more than a conflict of opinion among reputable surgeons as to the technic of operative procedure or as to when it is indicated? Or does it disclose that Brinkley was using his license to perpetrate a cruel hoax on the public by exacting extravagant fees for a trivial and worthless operation? Did Brinkley endanger the health of his patients by seducing them into the belief that serious diseases could be cured by a surgical hocus-pocus? Whether it is the one or the other, the court said, is a question peculiarly for the decision of men skilled in anatomy. There is, observed the court, a great volume of evidence in the record to support the latter conclusion; and if such is the fact, the board would have been derelict if Brinkley's licen-

tion under the base or margins of the indurated area. If the arterial pulsations are palpable, if proper elevation and continuous hot boric acid dressings do not relieve the pain, a crushing of the posterior tibial and saphenous nerves can be done through a small incision, 5 or 6 inches above the ankle. Should the ulcer be above or around the external malleolus, the superficial and deep peroneal nerves can be crushed. This procedure requires a skilful surgeon with experience in such operations.

#### HABITUAL ASTHMATIC ATTACKS

*To the Editor:*—A patient of mine who is subject seasonally to hay fever and asthma during the grass season period (May and June) has this year had severe attacks of asthma, especially at night, necessitating the administration of 10 minims (0.6 cc.) of epinephrine hypodermically to obtain relief. I instructed the patient how to administer the drug hypodermically and informed her to use it only during the severe attacks at night. The patient informs me that she still gets attacks at night. Although she has no wheezing or noise in her chest she gets attacks of shortness of breath at about 3 a. m., which is relieved only by hypodermic administration of epinephrine. She is entirely free from attacks of shortness of breath in the daytime. She commenced to use the drug June 29 and is still continuing to use it once at night up to the present time. Is it possible that she developed the epinephrine habit? Is there such a susceptibility to the drug? Please advise me what I can do to break the habit of this patient from the epinephrine injections. Please omit name.

M.D., Pennsylvania.

*ANSWER.*—It is obvious that the patient has a habit, though it is probably not an epinephrine habit. It is reasonable to suppose that there is some unbalance of the autonomic nervous system, produced at that particular time by some physiologic process, possibly one taking place in the digestive system. It is probable that ephedrine taken by mouth the last thing at night might prevent this 3 a. m. occurrence. Owing to its insomnia-producing tendency, the ephedrine should be combined with phenobarbital, in the following prescription:

R Ephedrine sulfate ..... 0.30  
Phenobarbital ..... 0.60  
M. and div. into 10 capsules.  
Label: One at bedtime and repeat once or twice if required.

The patient would then, of course, have to be weaned of the necessity of taking these capsules, which might be done possibly by progressive reduction of dosage in subsequent prescriptions. This should be easily possible if the cause for the allergic reaction has meantime been discovered and eliminated.

#### OSTEOMYELITIS OF STERNUM

*To the Editor:*—Late last February I did a whole thickness skin graft for a third degree burn over the upper part of the sternum on a young girl. This was only partially successful, as the upper part of the graft was lost as the result of infection. Two weeks ago she began to complain of pain and tenderness in this area. There is no fever nor is there any swelling about the area, which has been healed for nearly six months. I do not understand the reason for this pain and tenderness and can find nothing that covers this subject in the literature that is available. Could you give me any information as to the reason for this condition and what may be done to give relief from pain? Please omit name.

M.D., New York.

*ANSWER.*—It is difficult to give an explanation of the symptoms in this case from the facts as given. One would have to think of the possibility of a low grade osteomyelitis of the sternum. If the bone was uncovered as a result of the original injury, low grade infection might develop and go on to bone destruction even after a considerable interval of time and after the surface wound was healed. A stereoscopic x-ray examination would be of value.

#### TREATMENT OF UNDESCENDED TESTICLE

*To the Editor:*—What is the proper treatment for undescended testicle in a youth of 10 years? There is a fullness in the inguinal canal on the right side that is not present on the left. However, a definite testis is not palpable. The descended testicle and penis are smaller than normal. Is the medical treatment of this condition with the pituitary hormones effective? If so, which one would be most satisfactory? At what age should operation be considered?

LEO SCHWARTZ, M.D., New York.

*ANSWER.*—Operation, if performed by one experienced in surgery of this type, is the most certain procedure for obtaining a good result in a child of 10 years with undescended testicle. Treatment with gonadotropic extract of pregnancy urine should be given a trial and if the results are unsatisfactory, surgery can be resorted to. Two well known preparations for the medical treatment of undescended testes are antuitrin-S (Parke, Davis & Co.) and follutein (E. R. Squibb & Sons). The optimal time for operation is prior to puberty; however, it may be performed at a later date.

#### OXYGEN-CARBON DIOXIDE IN PNEUMONIA

*To the Editor:*—Is it permissible or advisable to use oxygen 95 per cent and carbon dioxide 5 per cent in an oxygen tent in cases of respiratory embarrassment? Would the use of this mixture through an oxygen tent over a period of time have a tendency to injure the patient? Also advise whether this oxygen-carbon dioxide mixture is suitable to use with a pulmotor in case of respiratory embarrassment.

M.D., Georgia.

*ANSWER.*—In the treatment of pneumonia a mixture of .95 per cent oxygen and 5 per cent carbon dioxide may be used for short periods. But for continuous use oxygen alone at flows sufficient to maintain an atmosphere of 50 or 60 per cent of oxygen in the tent is believed to be best. In this atmosphere the carbon dioxide from the patient's exhaled air may without harm, and even with advantage, be allowed to rise to 2 or 3 per cent. For purposes of resuscitation from asphyxia, drowning or electrical shock the mixture of oxygen and carbon dioxide should be administered by means of an inhalator. A mixture containing 7 or 8 per cent of carbon dioxide is more effective than one of only 5 per cent. Such mechanical devices as the pulmotor are unsound and unphysiologic.

#### SEROUS EXUDATE IN APPENDICITIS

*To the Editor:*—I have found twice during my experience of thirty-two years, while operating for appendicitis, free, almost colorless fluid in the abdomen, perhaps not exceeding a liter in amount. One patient was a girl, aged 12 years, and the other a woman, aged 25, both otherwise healthy. The appendix in each case was just slightly congested and a trifle swollen. One was free in the abdominal cavity and the other was adherent to the mesentery. I have no explanation for this condition and can hardly explain it on the basis of allergy. I would greatly appreciate your opinion.

G. L. GABLER, M.D., Holyoke, Mass.

*ANSWER.*—In view of the existence of acute appendicitis in both cases, the increased fluid in the peritoneal cavity most likely was a serous exudate from the inflammatory reaction in the peritoneal covering of the appendix and perhaps elsewhere.

#### GENEVA OPHTHALMOSCOPE AND RETINOSCOPE

*To the Editor:*—Please give me complete details on the Geneva ophthalmoscope and retinoscope, as to design and practicability.

R. N. MONFORT, M.D., Onaway, Mich.

*ANSWER.*—The Geneva ophthalmoscope and retinoscope was devised many years ago by Dr. E. J. Brown of Chicago and was manufactured by the Geneva Optical Company, which is now defunct. A complete description of the instrument can be found on pages 142-143 of the catalogue of the Geneva Optical Company that was published in August 1922. As an ophthalmoscope, the instrument left much to be desired for there was a great deal of spherical aberration and only the posterior pole of the eye could be examined. It lacked flexibility. The retinoscope phase of the instrument was rather complicated and unwieldy and lacked accuracy.

#### RELATION BETWEEN BLOOD AGGLUTINATION TEST IN TYPHOID AND MALTA FEVER

*To the Editor:*—I should like to know whether there is any relation in the blood agglutination tests between typhoid and Malta fever. I have had at least two patients who have had positive Malta blood agglutination and after four weeks of treatment with metaphen intravenously twice a week and nonspecific protein the tests have returned positive for typhoid. Please omit name.

M.D., Texas.

*ANSWER.*—So far as is known there is no immunologic or antigenic relation between the typhoid bacillus and Brucella abortus, the organism that causes Malta or undulant fever. It would be of interest to know the exact composition of the nonspecific protein used in the treatment of the patients; also whether the patients ever had typhoid or had been injected with typhoid vaccine.

#### DEVICE FOR LOOSENING STUCK SYRINGES

*To the Editor:*—Will you please give me the name and description of any device that is available to use for loosening stuck syringes? Please omit name.

M.D., Illinois.

*ANSWER.*—In addition to the method described by Dr. J. B. Hopkins in his letter to the editor in THE JOURNAL, February 6, page 492, there is a device known as the Plung-Ejector, which is used to loosen stuck syringes. A new model of the Plung-Ejector having several improvements over the old model has only recently come on the market. The new model is made with a rubber collar which tightly clamps the tip of the syringe

after transfusion. My associates and I had all the time we needed in which to search for agglutination and hemolysis, and to perform all the tests we knew about. We were not able to demonstrate any cross agglutination or hemolysis in some of these cases.

#### The Treatment of Undescended Testes

DRS. W. O. THOMPSON, A. D. BEVAN, N. J. HECKEL, E. R. MCCARTHY and PHEBE K. THOMPSON, Chicago: In contrast to the large proportion of successful results (70 per cent on the average) reported by various observers in the treatment of undescended testes with an anterior pituitary-like substance, we were able to produce descent in only about 20 per cent of the cases. In four of five cases showing descent, the testis could be pulled to the upper end of the scrotum or nearly to this level before treatment was started. In all successful cases descent occurred within one month, but stimulation of genital growth persisted much longer. In all patients treated surgically after prolonged administration of anterior pituitary-like substance, anatomic factors making descent difficult or impossible were present. However, the stimulation of genital growth produced by preoperative treatment with this material seemed to make surgical procedures less difficult. It would thus appear that, in the present state of our knowledge, operative procedures are necessary in most cases of undescended testes but should be preceded by from four to six months of treatment with anterior pituitary-like substance.

#### The Four-Lead Electrocardiogram in Coronary Occlusion

DR. ANNE S. BOHNING, Chicago: Two hundred consecutive cases with four lead electrocardiograms diagnostic of coronary occlusion were followed over a period of three years. Six hundred and fifty curves were analyzed in detail. The complete evolution of the four lead electrocardiogram in anterior and posterior infarction was demonstrated. Four lead electrocardiograms in thirty-five autopsies following coronary insufficiency, including twenty-five cases of coronary occlusion, were studied. The differences in the form of the electrocardiographic variations in the types of coronary insufficiency and infarction were analyzed. The striking ST variations associated with acute thrombosis are contrasted with the changes seen in the more slowly developing myocardial involvement produced by occluding sclerotic plaques.

#### DISCUSSION

DR. HAROLD FEIL, Cleveland: I should like to ask Dr. Bohning whether the electrocardiograms of patients who have been digitalized have not been difficult to differentiate from those of patients with recent infarction, especially when only one record has been taken.

DR. L. N. KATZ, Chicago: Several things should be emphasized about this study. The evidence is clear that one can differentiate between the classic electrocardiogram of thrombotic closure and the less typical electrocardiogram of the arteriosclerotic closure with its associated coronary sclerosis. The use of serial curves gives a fairly complete idea of the time course in coronary occlusion and also the rate of healing. The record before an attack may be normal or abnormal. Full recovery as revealed in the electrocardiogram may take a month or a year or two or may never occur, the patient showing a stabilized abnormal type of electrocardiogram for years. If these facts are borne in mind, some of the confusion in interpreting such electrocardiograms will be avoided and the usefulness of these records will be enhanced. The time has come it seems to me to establish a standard location for the fourth lead. There is too much confusion in this regard in the literature. Perhaps a committee should be appointed to investigate this matter. My associates and I have been placing the chest electrode in the fourth interspace just to the left of the sternum. This is over the area of solid dullness and is more apt than other localities to pick up the electric currents from silent areas of the heart. This site can easily be defined by any technician, intern or doctor, so that variations in serial records have more significance. The practice of placing the chest electrode over the apex of the heart, I believe, should be discarded, as this is a variable point as regards both the chest and the heart itself. If it is deemed essential to use a second spot besides

the parasternal one, the fourth interspace in the anterior axillary line may be employed. We have not found that this last site, or any other, is more informative than the one we generally used. The location of the distant electrode is not so important. We have found it most convenient to use the left leg electrode for this purpose.

DR. A. R. BARNES, Rochester, Minn.: The idea is put forth in the discussion that it is possible to detect by the electrocardiogram myocardial fibrosis produced by gradual coronary narrowing and by sclerotic plaques. I think that yet remains to be proved. In the first place, I see a great many patients who have advanced coronary disease, with partially occluding plaques and with extensive myocardial fibrosis, who do not have diagnostic changes in either the standard or the chest leads. If that case is complicated by hypertension there is very apt to be a negative T wave in lead I, with a low RST segment and a tendency to elevation of the ST segment in lead 3. To my mind that is the result of chronic left ventricular strain and is not a product of gradual occlusive disease. I know that this is a statement which will be challenged readily. I have had two or three experiences lately which seem to lend a little bit of evidence to support that idea. Certain patients with hypertension have been subjected to splanchnic resection, which resulted in a lowering of the blood pressure. Before operation these patients had a negative T wave in lead I and after operation the T waves came back to normal, indicating that the probabilities are that relief of the ventricular strain results in a restoration of the T waves to normal. I would emphasize that in hypertension there exists a variation of the ST segment which must not be confused with or taken to mean evidence of coronary disease. I agree with Dr. Katz that some standard point is needed at which to place the fourth lead. More should be known about it. The fourth lead is distorted by hypertension, acute pulmonary emphysema, congenital heart disease, pericarditis, bundle branch block and digitalis therapy. There are many facts that must be taken into consideration before concluding that the fourth lead is diagnostic of coronary disease.

DR. DREW LUTEN, St. Louis: Regarding the location of the chest lead, I agree with Dr. Katz and Dr. Barnes in their insistence on specificity. It would appear, however, that one should take pains to state the location of the lead rather than to insist on its being in a particular place. Dr. Goodman in our laboratory made many records of a single normal individual, placing the exploring electrode on various places on the chest wall. He then made a large drawing of the chest and pasted on it the electrocardiograms led off from the various places, so that at a glance one can compare the records made from different places. This comparison of records shows the importance of stating where one puts the chest electrode.

DR. ANNE S. BOHNING, Chicago: In answer to Dr. Feil, I may state that in all the cases it was known how much digitalis had been given before each electrocardiogram. It is not so difficult to differentiate digitalis changes in the T waves from true myocardial injury as is sometimes thought. My associates and I have a large group of serial electrocardiograms, and in most of these we can clearly differentiate digitalis changes. We do not use digitalis a great deal in our cases of coronary occlusion but somewhat more often in arteriosclerotic patients. In none of the cases shown was digitalis given in large amounts. As far as bundle branch block is concerned, it does obscure the electrocardiographic picture in cases of myocardial infarction. In a number of the autopsies there were septal infarctions but these cases did not show characteristic changes in the electrocardiograms. Seemingly, if the septal involvement is near the apex or lower third of the septum, it does not always appear in the electrocardiogram. When the septal infarction is extensive, it does complicate the electrocardiographic picture, but serial curves usually show ST and T changes between records which aid in diagnosis. There were many cases of hypertension, and most of them showed myocardial involvement at autopsy. I do not believe that hypertension itself has an effect on the electrocardiogram. Certainly the position of the heart in the chest will change the form of the electrocardiogram, especially the form of the QRS complex, and hypertensive cases usually show a left ventricular preponderance. We have carried out extensive studies in a large number of

of whom passed. Eleven physicians were licensed by reciprocity and 1 physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical F. . . . .		(1936)	1

### Illinois October Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education, reports the written and practical examination held in Chicago, Oct. 20-22, 1936. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Eighty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine . . . . .		(1936)	82
Chicago Medical School . . . . .		(1932)	82
80, 81, 82, 82, 82, 83, 84, 84, 84, 84, 85, 86, 86

removed. I think, as Dr. Scott does, that it does not make much difference to which group these cases belong. Dr. Edwards' patient, reported in 1906, lived eighteen years with the auricular fibrillation. One of the points mentioned was the effect of digitalis preparatory to quinidine therapy. In some of these cases it takes prolonged use of quinidine to restore the normal mechanism. Quinidine tends to produce ventricular extrasystoles and to accelerate the heart rate. I am a warm advocate of the use of quinidine with digitalis.

DR. MOSES BARRON, Minneapolis: The use of quinidine in auricular fibrillation has interested me for many years. From my experience at the General Hospital in Minneapolis and from private practice I feel that the danger of producing emboli is exceedingly slight; indeed, in my opinion the proper use of quinidine tends to prevent the production of emboli. If it is remembered that the causes of thrombosis are (1) auricular fibrillation and (2) congestive heart failure, it will be realized that the continuation of fibrillation will predispose to thrombosis within the auricles which may later result in emboli. The reason digitalis is first given is to strengthen the heart's action and reduce the congestive heart failure. Quinidine is then administered to try to establish the normal rhythm and prevent the formation of thrombi if they are not already present. If a patient is watched for congestive heart failure for a long time and if the heart's action is not improved, quinidine should not be given. Dr. Katz is right in emphasizing that quinidine is not to be given in hopeless cases of congestive heart disease.

DR. S. A. WEISMAN, Minneapolis: In regard to Dr. Katz's question, Is there any difference between a slow fibrillating heart and one restored to normal rhythm? Recently Dr. Kerkhof of the University of Minnesota investigated this point in a series of twelve cases of mitral stenosis. The patients were first digitalized until the pulse rate was down to between 60 and 70. The minute volume was determined. Quinidine was then given and after the heart was restored to normal rhythm the cardiac output was again determined. In this group he found that the cardiac output increased about 30 per cent after the heart was restored to normal rhythm. Is quinidine dangerous in auricular fibrillation? I believe that it is more dangerous not to give quinidine in auricular fibrillation. As I said before, fibrillation slows the circulation. This is a predisposing factor to thrombus formation. In my experience I have not had any serious toxic effects or emboli that I could definitely attribute to the use of quinidine. Hochrein has used quinidine in very small doses in all cases of cardiac failure coming to his hospital since 1926. He believes that quinidine helps to prevent ventricular fibrillation, which is probably the cause of sudden cardiac deaths. He and his associates have found that since they have used 0.1 Gm. of quinidine as a routine in all cases of cardiac decompensation they have had fewer deaths from cardiac failure. I have not had much experience with flutter. As far as the effect of quinidine and digitalis is concerned there is no question that the two drugs work much better together. That was shown by the work of Weiss and Hatcher. They determined the amount of quinidine that was lethal for a cat and also the amount of digitalis that was lethal for a cat. They found that when they gave a combined lethal dose of digitalis and quinidine this combination did not kill the cat, showing that these drugs do not have a synergistic action on the heart. On the contrary, they have a favorable action. In regard to giving large doses of quinidine, I do not think that the concentration of the blood should be rapidly increased with the drug. So far as I am concerned, the small dose method is the one that is the least dangerous. By giving quinidine in large doses there is more danger of producing toxic symptoms.

#### Syncope of Patients with Hypersensitive Carotid Sinus Reflexes

DR. H. L. SMITH, Rochester, Minn.: I have studied fifty patients who came to the clinic complaining of dizziness and syncopal attacks, and in each instance I was able to reproduce these attacks of dizziness and fainting, and in some instances generalized convulsions, by making graded pressure on one or both of the carotid sinuses. Forty-eight of these patients were males and two were females. Stimulation of the carotid sinus, produced by making pressure over the carotid sinus, induced rather striking cardiovascular reactions, such as slowing of

the heart rate, varying periods of cardiac standstill (usually associated with marked fall in blood pressure but not always), and paling of the face followed by flushing. These reactions occurred in varying combinations. The most striking reaction was the long periods of cardiac standstill. It is believed that the cardiac arrest is probably attributable to a temporary suppression of the sinus, thus depriving the heart of its normal pacemaker. The major cerebral symptoms are apparently attributable to cerebral ischemia brought on by slowing and stopping of the heart. I do not believe that cardiac slowing and cardiac standstill explain the entire picture. I feel certain that there are other factors also present. In a few instances I was able to induce rather severe attacks and the cardiac rate slowed only a few beats per second, and in other cases rather long periods of cardiac standstill were produced which were not accompanied by unconscious attacks. In other words, in most instances there was a definite correlation between the cardiac standstill and the syncopal attack, but not in all instances.

#### DISCUSSION

DR. JUSTIN C. WILLIAMS, Chicago: I should like to ask Dr. Smith whether he has had any experience with a younger group of persons. I notice that most of his patients, as mine were, were in the older group. The significance of that has something to do with what I am going to say. Dr. Weiss of Boston has reported that these carotid sinuses are more hypersensitive in the arteriosclerotic group, in the hypertensive group and in those having coronary disease. I have just completed a series of 106 cases. I selected the patients because they were ambulatory and because they were suffering from convulsions. The idea was to find out how many in that group would respond to pressure on the carotid sinus. I found about ninety-six who did respond in various degrees with slight slowing of the heart, and yet some of them would go into convulsions. I started this series with the warning in mind which Dr. Herrick gave me some time ago, that pressure should not be prolonged too long on these carotid sinuses. As I went along I got a little bolder about it and discovered that the heart, although it does go into systole for a time, allows ventricular escapes even during pressure on the carotid sinus. Contrary to that is one individual, aged 63 years, who was examined several times, and each time the time of pressure was increased. There were no ventricular escapes during the time of pressure, which has been kept on for nine seconds, with systole for nine seconds. The pressure has been released and then the heart starts up again. I think this justifies the warning Dr. Herrick gave that if one is going to test these people one must be careful in not prolonging the pressure. Often a supposedly coronary death comes to the postmortem table and no evidence of pathologic change as far as the coronary arteries are concerned is found. These people supposedly die of angina pectoris. I am wondering whether these carotid sinuses have anything to do with that kind of death. I am starting to investigate a group of coronary cases now and shall have something to report later. It may be pertinent to give another story because it involves a group of young people. A group of high school age occasionally gathered for the evening. Some of them discovered that one, a young girl, could be thrown into a fit by pressing on her neck. Evidently somebody had located her carotid sinus, and she very willingly submitted to the entertainment for the evening. They kept it up so long that the girl finally got sick and was brought to the emergency service of the West Suburban Hospital. By the time I got there she had recovered. The interns who got the case had been working with me on this problem, and they gave the girl a lecture. The mother had been sent for and her reaction was also interesting; she thought probably it was a better form of amusement than going to taverns.

DR. S. A. WEISMAN, Minneapolis: I did some experiments on dogs to determine the effect on the reflexes of the carotid sinus by increasing the intracranial pressure. The results were published. During this work another experiment, which was not reported, was done to determine the fatigability of the carotid sinus reflex. The carotid sinus was pressed between the fingers every thirty seconds for several minutes. After five to six minutes the reflex action diminished, and after about fifteen minutes mechanical stimulation had no effect on it.

culties that may arise during or following certain operations. These are definitely the fruit of long experience and are particularly valuable. In the main, most of the technic described follows the standard procedures practiced in this country. However, here and there one notes a departure with which one may not agree. For instance, the type of laryngectomy he advocates, the external ethmoid operation and the tonsil and adenoid operation in children are technically not quite the same as those we have been doing. The text is brief, yet clear and straightforward, and includes sufficient data on diagnosis and indications to amplify its usefulness. The book may be considered a useful addition to any laryngologist's library.

**Pathological Physiology and Clinical Description of the Anemias.** By William Bosworth Castle, M.D., S.M., Associate Professor of Medicine, Harvard University, and George Richard Minot, M.D., S.D., F.R.C.P., Professor of Medicine, Harvard University. Edited by Henry A. Christian, A.M., M.D., LL.D., Hersey Professor of the Theory and Practice of Physic, Harvard University. [Reprinted from Oxford Loose-Leaf Medicine.] Cloth. Price, \$3. Pp. 205. New York: Oxford University Press, 1936.

Interest in the anemias, greatly stimulated by the discovery of the efficacy of liver in the treatment of pernicious anemia, has led in the past decade to many important investigations, both at the bedside and in the laboratory. Etiologic concepts in many instances have been modified or completely changed. The concept of a "conditioned" deficiency state in pernicious anemia is entirely new. In the field of therapeutics, liver therapy in pernicious anemia has been perfected and there is a better understanding of the use of iron in the treatment of hypochromic anemias. The researches of Drs. Castle and Minot on these and many related problems are universally known and authoritative, and these authors are unusually well qualified to present the material in a book of this kind. The work originally was written for Oxford Loose-Leaf Medicine and subsequently was published separately by the Oxford University Press in order that it might be made generally available.

The authors have drawn freely from their own experimental work, their wide clinical experience and the literature. In so doing they have collected a vast amount of material, much of which is of such recent origin that only workers in the same field or in closely related fields would be thoroughly acquainted with it. In the opening chapter of the book there is a brief review of the normal physiologic processes of formation and destruction of blood and their reflection in the peripheral blood. This is followed by a presentation of important diagnostic methods that should be utilized in studying cases of anemia. The anemias are dealt with in subsequent pages and are taken up in logical sequence. Their classification is based primarily on etiology. As suggested by the title of the book, emphasis is placed on the pathologic physiologic processes that are of fundamental importance in the causation of the various types of anemia, for it is obvious that such knowledge is requisite not only to a complete understanding of disease but to rational therapy. Because the book is written from the physiologic rather than the pathologic point of view, detailed morphologic descriptions of the cells of the blood and hematopoietic organs are not included.

Although it is difficult in a work of such general excellence to select subjects more thoroughly treated than others, attention should be called to the masterly presentation of the macrocytic anemias, a field in which there have been many important contributions in recent years. The authors stress the fact that the physiologic defect in erythropoiesis in the macrocytic types of anemia is concerned chiefly with cell production; in the hypochromic types of anemia, with hemoglobin formation. Of primary interest is the first group, in which insufficient red cell production has been shown to be attributable to nutritional deficiency of the bone marrow, a deficiency of substances essential for regeneration of red cells. This deficiency may be attributable to (1) failure of the gastric mucosa to secrete a substance, the antianemic principle or intrinsic factor of Castle, (2) defective diet (low in the extrinsic factor of Castle) and (3) disturbances in absorption from the intestinal tract or a combination of these factors. Various diseases in which macrocytic anemia may develop include addisonian pernicious anemia, sprue, pellagra, tropical macrocytic anemia of pregnancy, "pernicious (macrocytic) anemia of pregnancy" and certain pathologic conditions of the gastro-intestinal tract (gastric carcinoma, gastric polyps, chronic pyloric stenosis, intestinal stricture,

idiopathic steatorrhea, *Diphyllobothrium latum* anemia and so on). The macrocytic anemia of hepatic disease is discussed in the section dealing with idiopathic disturbances of the blood-forming organs, since its etiology is not as yet clearly understood.

In the concluding chapter there is a splendid presentation of modern knowledge of therapy; the discussion first is taken up from the standpoint of general methods of treatment and ends with a presentation of therapy in specific types of anemia. Appended is an extensive bibliography arranged according to subject.

This work, although not long, contains a wealth of information. It is clear, concise, and written in an easy, readable style. The publishers are to be commended for the type, the paper and the format, which are excellent. The book is to be highly recommended to students and practitioners of medicine.

**Aspectos de la sífilis congénita en nuestro medio.** Por los Doctores Julio Lorenzo y Deal, director del Hospital Pereyra Rossell, y Rito Etchegaray, médico del dispensario No. 11 del servicio protección a la infancia. Publicaciones del Departamento científico de salud pública, Serie 2, núm. 17. Paper. Pp. 91. Montevideo, 1935.

This is an earnest and serious study of one of the most important and often neglected aspects of venereal diseases: congenital syphilis. In their respective capacities as director of a children's hospital and physician in a children's dispensary in one of the largest South American cities, the authors speak authoritatively on their chosen subject. Among 20,000 case reports from Montevideo hospitals, dispensaries and private practice, 200 cases of congenital syphilis were found; i. e., 1 per cent for the group as a whole, and 1.45 per cent for 3,242 infants. Another Uruguayan writer, Burghi, quoted much higher figures: 11.8 per cent among 1,231 infants; but Morquino gave only 0.26 per cent for 3,000 infants, Navarro 3.18 per cent, and Infantozzi's obstetric clinic shows 3 per cent among 7,822 births in the period 1929-1933, García San Martín's 2.44 per cent among 6,949 births in his clinic, Canzani 0.66 per cent among 300 births, and Pacheco 0.26 per cent among 2,650, the two latter being among private patients in the upper classes. During the last decade the symptoms of the disease seem to have decreased both in seriousness and in prevalence in Montevideo. Among serologic methods the Kahn test proved most sensitive, with 77 per cent positive results among clinical cases. Only three cases in twins were found in the series. This is an interesting report, filled with valuable data on an important public health and social problem, which must await solution until all agencies concerned, and especially society as a whole, extend their full cooperation to the medical profession and the health authorities.

**Keeping Your Child Normal: Suggestions for Parents, Teachers and Physicians; With a Critical Estimate of the Influence of Psychoanalysis.** By Bernard Sachs, M.D. Cloth. Price, \$1.50. Pp. 148. New York & London: Paul B. Hoeber, Inc., 1936.

This small book is a slightly expanded form of a similar publication by the same author issued in 1926. One or two new chapters have been added, giving valuable suggestions for parents and teachers with regard to the care of normal children, particularly those of school age. Much of the advice is sound, for the author has a broad insight into nervous and mental problems and also into the common pitfalls for the child with a normal mind. Occasionally Dr. Sachs is too dogmatic in his utterances. On page 28, for instance, he states that "stuttering is definitely curable at all ages and surely in early childhood." Not a few physicians and even some of the author's colleagues wish that this statement were true. The bulk of the book, however, is given over to Dr. Sachs's critical review of psychoanalysis, particularly with relation to the use of the analytic method in patients under 18 years of age. The author feels strongly not only that the method is an unprofitable one to pursue but that it offers definite dangers. Patients have been made worse by prolonged analysis, some of them permanently. Dr. Sachs brings out all the standard arguments against psychoanalysis in a clear-cut and logical manner. Occasionally, however, he oversteps the bounds of scientific discussion when he uses such terms as "satellites" and "disciples" of Freud. There is much sound advice here, but the whole field is still somewhat controversial and one should not consider that the last word on the subject has been said by this author.

blood pressure following pregnancy was greater than in a control series. The tendency to increased blood pressure was accentuated by advanced age, increase in parity, overweight and family history of cardiovascular-renal disease.

**The Peripheral Circulation in a Patient with Raynaud's Phenomena Before and After Cervical and Upper Dorsal Sympathetic Ganglionectomy and Ramisectomy**

DRS. CARL A. JOHNSON and LOYAL DAVIS, Chicago: Studies were made on a married woman, aged 26, who presented moderately severe Raynaud's phenomena. Under uniform temperature conditions, observations were made in the fingers preoperatively and at various intervals postoperatively with regard to (1) skin temperatures, (2) blood pressures, (3) pulse, (4) body temperature and (5) peripheral pulse volume changes. In addition the effects of local heat and median nerve block were measured preoperatively and postoperatively. With these criteria as indexes of peripheral circulatory efficiency, the results indicated a return of the peripheral circulation to the preoperative level in sixteen days. The discussion covers similar results in other patients.

DISCUSSION

DR. GÉZA DE TAKÁTS, Chicago: These observations indicate that, following sympathectomy, vascular tonus is regained within sixteen days. This does not mean, however, that central or reflex stimuli of extrinsic or intrinsic origin can reach the blood vessels. The work of Carmichael in England, that of Richard Capps and my own observations show that the vessel which is sensitive to reflex stimulation by cold, pressure, pain and deep breathing is now uninfluenced by such reflexes and is put at comparative rest. Aside from this, another objective finding, which persists after operation, is the rise of oxygen saturation in the venous blood. The statement that peripheral circulation returns to the preoperative level in sixteen days must be modified to indicate that vascular tonus is regained; but the lasting vasomotor palsy institutes changes in circulation which favorably influence peripheral vascular disease.

DR. CARL A. JOHNSON, Chicago: In answer to a question as to whether the completeness of the sympathectomy was checked by loss of sweating, I wish to say that there was an absence of sweating in the operated arm as well as a Horner's syndrome of the eye of the operated side. With regard to the remarks of Dr. de Takáts, we merely wished to show by these experiments that the circulation as measured by the plethysmograph returns to the preoperative level in a comparatively short time. In this particular patient it was sixteen days, while in another patient it was twenty-one days. The vessels apparently regain their preoperative tone by mechanisms that are independent of the normal sympathetic vasoconstrictor tone.

**Origin of Symptoms of Neurocirculatory Asthenia**

F. K. HICK, PH.D., W. A. CHRISTIAN, M.D., and P. W. SMITH, PH.D., Chicago: Neurocirculatory asthenia showed in thirteen cases an inadequate arterialization of blood leaving the lungs. This supports the opinion of Haldane that part of the symptoms of these patients are from anoxemia. It supports the explanation that irregularities in breathing are from oxygen want. These patients are not uncommonly diagnosed as having hyperthyroidism. If one is able to establish the presence of an oxygen want, cases presenting basal metabolic rates artificially elevated by inhalation of oxygen may be separated from those showing a true elevation.

DISCUSSION

DR. ROBERT W. KEETON, Chicago: Views have been changing with reference to these cases from time to time. This study represents an attempt to analyze the mechanism of the symptoms. From the paper it seems possible to attribute many of the symptoms to an oxygen want. When the patient is short of breath and uncomfortable he shows an oxygen want; when he feels well the oxygen want has disappeared. When the respiratory abnormalities appear there is oxygen want. When the patient breathes oxygen they are lessened. In short, there is a correlation between oxygen want and the patient's symptoms, including his respiratory irregularities. When one sees these patients make complete recoveries after a psychic or social

adjustment, one is led to believe that one is dealing with a profound alteration in the individual's physiologic behavior and that one disabling element in this alteration is an arterial oxygen deficit.

DR. J. A. GREENE, Iowa City: I have been interested in studying the expiratory volume of the chest in patients and have observed a few cases of neurocirculatory asthenia. The expiratory chest volume increases with any stimulation of the respiration, and in some instances expiratory inflation becomes extreme. Under these circumstances the patient is unable to deflate the lungs. The great expiratory volume of the lungs and the rapid shallow breathing do not permit adequate ventilation; therefore the oxygen that has been stored in the inflated lungs becomes depleted, and cyanosis develops. Expiratory inflation is a normal response to respiratory stimulation, but in these cases this mechanism is exaggerated. This exaggerated response is apparently the cause of the shortness of breath and is an important factor in their cyanosis. The dyspnea and air hunger encountered in patients with cardiac failure are apparently due to a different mechanism.

DR. FORD K. HICK, Chicago: I think what happens to these patients is that the ventilation increases.

**Early Effect of Total Thyroidectomy in Polycythemia Vera**

DRS. LOUIS R. LIMARZI, ROBERT W. KEETON and LINDON SEED, with the technical assistance of DRS. FORD K. HICK and M. H. STREICHER, Chicago: Studies have failed to clarify the etiology of polycythemia vera, and the methods of treatment have not produced a lasting success. Total thyroidectomy was performed in a case of primary polycythemia because of the anemia and decreased blood volume that is found in some cases of spontaneous myxedema. Studies performed at intervals extending over a year following the total thyroidectomy show a gradual and progressive decrease in the blood volume and hematocrit value, a marked fluctuation in the number of erythrocytes with a gradual drop toward normal, and a change of the blood from a state of oxygen want to one with a normal value. These values have not as yet reached a normal one. It remains to be seen whether the persistence of the myxedema will result in normal hematologic values.

DISCUSSION

DR. ROBERT W. KEETON, Chicago: In presenting these cases it is obvious that we are not offering a solution of the disease, but we believe that we have arrived at a most satisfactory method of control. The blood volume, the total circulating hemoglobin and the volume of packed cells have been reduced. The patients have lost many of their symptoms and are comfortable except for the pains due to their myxedema. They believe that they have received benefit from the operation.

DR. G. E. WAKERLIN, Louisville, Ky.: I have seen one patient with polycythemia vera who received x-ray therapy to the region of the pituitary with a subsequent fall in the red cell count to normal limits and symptomatic improvement lasting six months. A second set of treatments was followed by a similar drop. On the basis of the work presented it appears likely that the beneficial effect obtained was induced through a depression of the secretion of the thyrotropic hormone of the anterior pituitary. On the assumption that similar results could be obtained with the x-rays in other polycythemia vera patients, the question of irradiation of the pituitary region versus total thyroidectomy is raised. There are obviously certain disadvantages and advantages to both procedures.

DR. W. O. THOMPSON, Chicago: Total ablation of the thyroid is rather popular just now. From the point of view of pathologic physiology I should simply like to say that hyperthyroidism does not produce polycythemia. I cannot recall any case of hyperthyroidism in which polycythemia was present. Although anemia is present in myxedema, it usually does not clear up when sufficient thyroid is given to maintain the basal metabolism at normal for a long time. There would appear to be some other factor involved in the anemia than underfunction of the thyroid gland. While the results of the authors are interesting, I should therefore think that a lot of confirmative data should be collected before recommending total thyroidectomy in the treatment of polycythemia.

had not been revoked. It is true that the great advances in medical science have come about by the courage of pioneers, whose efforts often met with ridicule from their professional brethren. It is true that physicians even yet disagree. It is also true that charlatans masquerading as physicians defraud the public to their own enrichment by promising to cure cancer with innocuous ointments and thus endanger the lives of their patients by depriving them of sound medical advice. Between these two extremes there is a twilight zone where doubts might perplex. But unless it can be said, from the record, that there is no doubt that this is a mere disagreement among physicians, the finding of the board is not open to review. The legislature had properly committed the vital question of the fitness of those who administer to the sick to a skilled board of medical men and not to courts unlearned in the art. The proof here, the court said, amply supports the conclusion that the "compound operation" was not an honest effort to relieve suffering, but a scheme for Brinkley's unjust enrichment.

Through regular broadcasts, continued the court, Brinkley diagnosed almost every ailment to which the human flesh is heir. Sometimes he told his patients to consult a physician; much more often he prescribed remedies, by numbers, which could be obtained from drug stores throughout the Middle West, to whom he had furnished the prescriptions and from whom he received a part of the price of some of the prescriptions. These diagnoses were made without an examination of the patient, and on only such symptoms as the patient would give in a letter or telegram. One need not be skilled in medicine, the court said, to understand the grave dangers to human life involved in diagnosis and prescription on such sketchy facts as are obtainable from a letter or a telegram; nor of the danger to thousands of others listening in who apply such advice to their own self-diagnosed diseases. It is no answer to suggest that the prescriptions were harmless in themselves; to prescribe bread pills to a diabetic patient whom insulin might save is to trifle with human life. The trial court aptly said:

Those methods are not only in conflict with the ethics of the profession but are in my opinion in conflict with the best interests of the public, and that irrespective of the value of the operations performed by him at the hospital for the amelioration of the prostate gland or of the benefits to individuals urging prescriptions given through radio broadcasting, the possibilities of injury to the general public resulting from such methods are so apparent if such practice became general and usual that its mere statement is, I think, sufficient.

It was for men trained in medicine instead of the law to determine whether Brinkley's conduct constituted unprofessional conduct. The board of medical examiners determined that it did so constitute and there was, the court said, substantial evidence to support its finding.

The members of the board, Brinkley contended, were prejudiced against him before the hearing started, and some of them were active in instigating the complaint. Without detailing the evidence, the court said, it does appear that some of the members of the board had expressed such prejudice, and doubtless all were in fact prejudiced. The publicity used by Brinkley, in the opinion of the court, made public prejudice well-nigh inevitable. At any moment the program on the radio might change from cowboy songs to the diagnosis of disease and the extolling of the "compound operation." That the members of the board had radios in their homes constituted no constitutional disqualification. One of the issues of the case was whether the radio talks were in fact given and whether they violated professional standards of conduct. The members of the board having radios thus had personal knowledge of the facts alleged, and necessarily formed some opinion as to whether they were in conflict with professional standards. The medical practice act provided only one tribunal with power to revoke a physician's license. If such powers may not be exercised if the members of the board are prejudiced, then any physician who commits an offense, so grave that it shocks every right thinking person, has an irrevocable license to practice his profession if he can get the news of his offense to the board before the hearing begins. This will not do, the court said. The commendable efforts of the medical profession to raise its standards by cleaning its own house cannot be set at naught by any such rule of law. The trial court,

after patiently hearing the evidence as to the attitude of mind of the individual members of the board, disposed of the contention in this language:

Under the general terms of the statute, the Medical Board is empowered to protect the public against conduct which is clearly against public interests and therefore necessarily unprofessional, the same as if the legislature had specifically denounced and prohibits such practice. The members of the board were not disqualified because they knew of his methods prior to the hearing and condemned them. John R. Brinkley's methods were so notorious that ignorance of them by members of the board was an impossibility and such knowledge compelled condemnation.

With this holding, the circuit court of appeals expressed itself as in entire accord.

After reviewing the entire record, at length, the circuit court of appeals concluded that Brinkley's constitutional rights were not infringed. The judgment of the district court against Brinkley was therefore affirmed.—*Brinkley v. Hassig*, 83 F. (2d) 351.

### COMING MEETINGS

- American Association for the Study of Neoplastic Diseases, Philadelphia, April 9-10. Dr. E. R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Anatomists, Toronto, Ont., March 25-27. Dr. George W. Corner, 260 Crittenden Blvd., Rochester, N. Y., Secretary.
- American Association of Pathologists and Bacteriologists, Chicago, March 25-26. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.
- Arizona State Medical Association, Yuma, April 1-3. Dr. D. F. Harbridge, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 12-14. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.
- Florida Medical Association, St. Petersburg, April 5-7. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Pacific Coast Surgical Association, Seattle, Wash., and Victoria, B. C., Feb. 24-27. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.
- South Carolina Medical Association, Columbia, April 13-15. Dr. E. A. Hines, Seneca, Secretary.
- Southeastern Surgical Congress, Louisville, Ky., March 8-10. Dr. Benjamin T. Beasley, 478 Peachtree St. N.E., Atlanta, Ga., Secretary.

### CENTRAL SOCIETY FOR CLINICAL RESEARCH

Ninth Annual Meeting, Held in Chicago, Nov. 6 and 7, 1936

The President, Dr. FRED M. SMITH, Iowa City, in the Chair

(Concluded from page 590)

#### Clinical Study of Serious Complications from Blood Transfusion

DR. ELMER L. DEGOWIN, Iowa City: Ten serious complications occurred in 2,500 blood transfusions. There were six cases of transfusion anuria, two cases of hemoglobinuria without anuria, one with symptomless jaundice, one with amaurosis from retinal hemorrhages. The six cases of transfusion anuria merit special attention. Five patients died of uremia and one recovered. No incompatibility between donors' and recipients' bloods could be proved in four of the six cases. Recognized therapy such as intravenous saline solution, dextrose and alkalis, phlebotomy, irrigation of the renal pelvis, x-rays and diathermy over the kidney regions, and spinal anesthesia was ineffective. Decapsulation of the kidneys or transfusion of compatible blood was not attempted. The exact etiology and treatment of this condition are not yet well understood.

#### DISCUSSION

DR. J. M. HAYMAN JR., Cleveland: I should like to ask what the specific gravity of the urine was in these patients.

DR. MOSES BARRON, Minneapolis: Was all the blood cross agglutinated?

DR. ELMER L. DEGOWIN, Iowa City: As to the specific gravity of the urine passed, after renal insufficiency has developed it is generally low and there is either oliguria or complete anuria. The question was asked about the incidence of cross agglutination. After these transfusion reactions occurred these cases were all checked by two or three methods. The donors were available. These patients all lived ten days

chronic ulcerative colitis. This by itself cannot be considered adequate and conclusive proof of the relationship. Bacteriophagy, also employed by different investigators, has similar defects and cannot thus be considered satisfactory sole evidence of such a direct relationship. Thus far there have been too few studies carefully performed to permit one to evaluate the factor of dysentery infection in chronic ulcerative colitis. But from the available evidence it may be concluded that about 10 to 15 per cent of cases considered clinically to be idiopathic ulcerative colitis rightfully belong to the category of chronic bacillary dysentery. The residual still remain in the group of the etiologically unknown. The gross clinical features and course of chronic bacillary dysentery and of nonspecific ulcerative colitis resemble each other so closely that differentiation is impossible unless a case is traced to a known and proved epidemic—an unusual event. Similarly the sigmoidoscopic and roentgenologic features are so similar that they cannot serve as reliable methods of differentiation. And even on the necropsy table there are few if any features which serve as adequate criteria for purposes of differential diagnosis. Despite these close resemblances there are other features which make one suspect that the two conditions are not dependent on a common etiology. Thus, in contrast to the age distribution of bacillary dysentery, a preponderance of cases of nonspecific ulcerative colitis is found in the third and fourth decades with surprisingly few cases in infancy and early childhood. Another discrepancy is discovered in the sex incidence, in which it is found that the disease occurs about twice as often in women as in men. Furthermore, despite the widespread distribution of epidemic bacillary dysentery throughout the armies on all fronts during the World War, the preponderance of males is at present below the age of 40 and mainly in the third decade who did not see service overseas. In addition, chronic nonspecific ulcerative colitis is not as prevalent in central Europe as one would expect from the prevalence of acute epidemic bacillary dysentery during the late war. Finally, the well known lack of infectivity of nonspecific ulcerative colitis, for which no authority known to the author has ever claimed infective properties, must be contrasted with the equally well known infectivity of cases of chronic bacillary dysentery, as pointed out by Walko and Schürer and Wolff. It is his impression that, taking the ulcerative colitides as a group, there will be found definite etiologic agents responsible for a relatively small number and that the larger residual group consists of a heterogenic conglomeration of conditions with variable etiology.

**Vitamin Deficiency in Diets in Diabetes.**—Sindoni investigated the diets of eighty-five diabetic patients, who suffered also from disturbances involving the gastro-intestinal, genitourinary, gynecologic and cardiovascular systems as well as the visual field and oral, neurologic, skin, joints and endocrine glands. The patients were obese; 5.4 per cent suffered from gangrene and 3.5 per cent from malignancy. They were still ignorant of the true nature of their condition—a factor in the causation of increased diabetic complications and mortality. They were on restricted diets, but none adhered to their prescribed diets. Avitaminosis and hypovitaminosis were found in every one of the patients. These disturbances were not the result of one vitamin but of several, as amply evidenced by the patient's dietary history, symptoms and physical disturbances. Many physicians adjust insulin dosage to the carbohydrate allowance only, disregarding proteins, fats, vitamins and other elements of diet. There was a marked correlation in vitamin-deficiency diets to the rise in the incidence of diabetes, diabetic complications or concurrent diseases, but no correlation in overeating. These observations determined the author to correct the diet of these patients. He strongly advocates a more detailed study of the patient's diet history as well as of the symptomatology. The diabetic patient's diet should consist of natural foods, rich in the essential vitamins and other elements, since such diet will more often result in greater adherence by the patient to his instructions. The following advantages will be obtained: (1) better cooperation of patient with physician, (2) less complications, symptoms or physical disturbances, (3) less insulin, (4) better metabolic equilibrium, (5) better outlook on life, (6) prolongation of the span of usefulness, (7) greater resistance to infection, (8)

avoidance of avitaminosis and hypovitaminosis and (9) more energy. Diets consisting of a variety of natural foods, such as vegetables, fruits, milk and its products, meat and cereals in prescribed proportions, with hygienic measures, such as sunshine, fresh air and exercise, will result in little need to worry about vitamin deficiency in diabetes.

**Hodgkin's Disease and Allied Conditions of Bone.**—Dresser and Spencer have seen sixty-six cases of Hodgkin's disease with 120 concomitant lesions of the bone. The greatest number of cases in their series were in the third and fourth decades. The youngest was 11 years of age, the oldest 83. The two sexes were affected equally. The roentgen picture usually simulates that of a metastatic malignant condition. It may, however, be confused with Ewing's tumor, osteogenic sarcoma, bone cyst, osteomyelitis or other inflammatory bone conditions. In no case is the roentgenogram entirely characteristic. Of the twenty-nine cases with involvement of the vertebrae, the process was destructive in all but two. As in malignant metastasis, the vertebral bodies were chiefly involved with preservation of the intervertebral spaces. In the pelvis the process is usually destructive. One generally finds large areas of bone erosion with sharply defined margins. The changes in the extremities are much more variable than in

cases, using multiple leads over the chest. Many of these were hypertensive patients as well as others with coronary occlusion and bundle branch block, and I can state with some assurance that these T changes are not found in one location only but more often show variations across the entire chest. It must be something other than the hypertension alone that causes the change in the electrocardiogram. It may be in the variation in the size of the heart and its altered relation to the chest wall, or it may be in a definite myocardial involvement, but certainly the cause of the electrocardiographic abnormalities must be associated with changed conditions in the heart itself. I do not believe that I stated that we differentiated sudden thrombosis from slowly occluding sclerotic plaques in interpreting our electrocardiograms. I have merely described and shown the differences observed in the types of electrocardiograms found in these autopsies grouped according to the observations made. I think it is worth while pointing out that these differences commonly occur. As far as  $T_4$  is concerned, we have seen a positive  $T_4$  in normal children up to 12 years of age and sometimes older and also in cases of bacterial endocarditis and rheumatic fever in children. We have also observed a number of other cases in which we could not explain the positive  $T_4$ . These  $T_4$  waves are, however, not of the type which suggests coronary occlusion. In most cases the  $ST_4$  is elevated rather than depressed. I think these changes are possibly associated with enlargement of the right side of the heart or rotation of the heart. I cannot say that it is due to these causes entirely, but  $T_4$  positive in such cases seems to be associated with a different placement of the heart in the chest. A positive  $T_4$  which is normal on the right side of the chest is probably carried over to the left in many of these patients, since in young children the right side of the heart lies more anteriorly than in adults. Most of these QRS<sub>4</sub> complexes associated with  $T_4$  positive are diphasic in children, while in coronary occlusion with anterior infarction the QRS<sub>4</sub> associated with  $T_4$  positive is mainly or entirely up.

#### Quinidine Therapy and the Method Used

DR. S. A. WEISMAN, Minneapolis: This is a six year clinical study of a method of giving quinidine to ambulatory patients with auricular fibrillation. The method is based on a laboratory animal experiment which shows that practically all the quinidine is eliminated from the blood stream one hour after the drug has been given intravenously. The patient is first digitalized. Quinidine is then given in very small doses one hour apart, and gradually each dose is increased. It is found that this method has two distinct advantages: 1. The patients establish a tolerance for the drug. 2. Rarely do the patients complain of the toxic symptoms so often attributed to quinidine. The results with this method show that in a series of cases of auricular fibrillation over 70 per cent were restored to normal rhythm.

#### DISCUSSION

DR. L. N. KATZ, Chicago: No one denies that slowing the heart relieves palpitation and other cardiac sensations, but it is extremely doubtful that the filling of the heart is improved at slow ventricular rates by eliminating auricular fibrillation. At rapid ventricular rates the absence of auricular filling is missed, but at slow rates the ventricles can make up this deficit. There is no need, therefore, to restore sinus rhythm on this account. Is it not much better to give quinidine in divided doses over twenty-four hours instead of concentrating the doses in one period of the day? After all, quinidine is excreted rapidly, most of it within four hours. Is it not the aim to maintain the maximum dose over a long period rather than to produce peak concentrations for short periods? Does Dr. Weisman advocate the use of quinidine indiscriminately in all cases of auricular fibrillation or does he follow the standard contraindications; namely, to avoid quinidine when the heart is enlarged, when the fibrillation is long standing and when heart failure is present? While no one denies that quinidine could be more widely used than at present, the majority of authorities still believe that there is some hazard connected with the use.

DR. C. C. MAHER, Chicago: I have been interested in the use of quinidine for some years, employing a somewhat different method but along the same line of thought. My early studies

were concerned with the duration of the effect of quinidine as measured by electrocardiographic changes. Most of these studies were made with chest leads directly over the base of the heart, showing the effect on the auricular rate. It appeared that, although the quinidine was rapidly excreted, the effect on the auricular rate remained for a period of twenty-four hours when the drug was given orally. If it is given intravenously the effect is apparent almost immediately and may last from four to six hours. The method of oral administration has been 3 grains (0.2 Gm.) six hours apart, continued throughout the night, such as Dr. Katz mentioned. That method of night dosage may seem somewhat impractical, but most cardiac patients are prone to wake up at least once during the night. I found early in my experience that the time element was an important factor. On that basis I keep the patients on quinidine over a long period. Some patients have not converted until they were on the drug for from six to eight weeks and some have taken from six to nine months or even a year before they converted. I have been most interested in studying patients who do not convert. Those in the rheumatic group appear to have some active infection and possibly an active myocarditis. In the arteriosclerotic group very often infections in the urinary or biliary tracts played a rôle. Occasionally mild thyrotoxicosis was discovered as a factor. I would be interested in asking Dr. Weisman what he does in patients on quinidine who develop chronic auricular flutter, a problem which is sometimes a baffling situation.

DR. ROY W. SCOTT, Cleveland: Dr. Weisman stated that the vast majority of his patients were in the hypertensive or coronary group, with a minimum number in the rheumatic group. I wonder whether the type of case treated was not the most important factor in his results, namely, the effect of quinidine in restoring a sinus rhythm in a high percentage of auricular fibrillation, and the absence of embolic accidents in the series of patients treated. I still believe that quinidine is a two edged sword and therefore I wonder whether such favorable results as here reported by Dr. Weisman would occur in a series of rheumatic heart cases with mitral stenosis and auricular fibrillation.

DR. CHESTER M. KURTZ, Madison, Wis.: I question the rationale of the routine use of digitalis preparatory to giving quinidine. The value of quinidine depends on its action as a myocardial depressant. Digitalis is a myocardial irritant. I wonder whether the administration of digitalis would not tend to counteract the desired effect of the quinidine.

DR. NORBERT ENZER, Milwaukee: The paper seemed to indicate that considerable emphasis should be placed on the relative occurrence of emboli in these fibrillating hearts. The statement was made that fibrillation was a common source of emboli. A recent review of my own not yet completed satisfies me that auricular fibrillation is in itself a less common cause of arterial occlusion. In my series I found mural thrombi from coronary lesions the most common cause and vegetations on the endocardium and valves next. The presence or absence of arterial emboli as an index of the value of a therapeutic procedure should be taken with caution. Further, arterial emboli do not necessarily take origin from the heart. In that respect, lesions in the brain should be interpreted with great caution. Vagaries of the cerebral circulation are too commonly causes of arterial occlusion.

DR. EDWARD W. HOLLINGSWORTH, Chicago: For a number of years I have been using quinidine, up to two or three years ago chiefly in cases of rheumatic heart disease. I have never seen an accident happen to any of these patients in whom sinus rhythm was restored. The last speaker mentioned the fact that hemiplegia occurred. I have seen two patients in whom I had reason to think that the hemiplegia was due to emboli, and postmortem examination showed a hemorrhage in one. I do not think it can always be said that embolism was the cause. One point which I noticed was that some patients seem to feel better when continued on small doses of quinidine even when sinus rhythm is not restored. I do not see any reason for this.

DR. HAROLD FEIL, Cleveland: I would emphasize the efficacy of treating hyperthyroid patients after operation. The quinidine should be used as a routine when normal rhythm is not restored by operation, because the cause of the fibrillation has been

**Calcium and Iodine Metabolism in Thyroid Disease.**—Puppel and Curtis determined the calcium and iodine balance pretherapeutically of one patient with hypothyroidism, two normal subjects and two patients with exophthalmic goiter. The calcium and the phosphorus content of the blood of all five subjects varied within normal limits. In the patient with hypothyroidism there was an increased retention of calcium over normal. In the two normal subjects on a low calcium diet the calcium balance was negative. In the two patients with exophthalmic goiter there was an increase in the amount of calcium excreted. In one the increase was almost entirely in the feces. In the other the increase was in both the urine and the feces. This resulted in a continuous negative calcium balance greater than normal. In the two patients with exophthalmic goiter the iodine balance was less than normal even in the presence of an intake of iodine which was at least normally adequate. The increased fecal excretion of iodine was greater than the increased urinary excretion of iodine, thus showing a difference from normal persons and from subjects with hypothyroidism. In the patient with hypothyroidism a decrease in the excretion of calcium accompanied the decrease in the circulating iodine. In the two patients with exophthalmic goiter an increase in the excretion of calcium accompanied the increase in the circulating iodine. In the patient with exophthalmic goiter maintained on a low intake of calcium, observations during three periods of three days each revealed that the iodine balance was continuously negative and that the calcium balance varied directly with the iodine balance. In the patient with exophthalmic goiter maintained on a high intake of calcium, observations during five periods of three days each showed that the iodine balance remained at a level definitely lower than that of the two normal controls. The calcium balance varied inversely with the iodine balance. In the other subjects maintained on a low calcium diet, observations during nine of twelve periods of three days each showed the calcium balance to vary directly with the iodine balance.

**Untoward Effects of Diuresis.**—The syndrome discussed by Poll and Stern is seen in connection with diuresis and is characterized by preliminary symptoms of weakness, restlessness and mental confusion (sometimes progressing to delirium and psychosis), which may be followed by apathy, coma and in some cases death. The turgor of the tissues may become poor, the tongue exceedingly dry and thirst extreme. Any or all of these phenomena should be borne in mind when a patient who has been subjected to diuretic therapy appears to be failing. The clinical picture may be produced without the use of mercurial diuretics and in no sense are these valuable drugs indicted. However, the syndrome is more likely to occur when mercurial diuretics are used, since their ability to cause rapid dehydration is more marked than that of any other available diuretic agent. When a patient who is subjected to dehydration therapy begins to fail, one must endeavor to decide whether any of the following factors are present and, if so, whether they are etiologic, contributory or only incidental to the clinical picture: irremediable myocardial insufficiency, fresh coronary thrombosis, exacerbation of rheumatic carditis, pulmonary infarction, infection of the respiratory tract, true renal insufficiency, cerebral vascular accident, excessive use of sedatives and the syndrome under discussion. Excessive use of sedatives is of great importance, as the edematous patient

with myocardial insufficiency is often extremely restless and large doses of sedatives are required to induce quietude and thus spare the myocardium. The stupor induced by rapid dehydration is too readily attributed to the use of sedatives. The authors' study of their case reports and of those recorded by other observers provides no entirely adequate basis for the prediction and exclusion of patients unfavorable for drastic dehydration therapy. The following factors should be taken into consideration and particular care should be exercised in their presence: old age, advanced atherosclerosis and cachexia. If, despite extreme precautions, untoward symptoms develop, therapy should be begun as soon as the syndrome is diagnosed or suspected. It consists of (1) the administration of water—by mouth if possible; (2) the administration of sodium chloride by mouth, at first in capsules and later as a 0.1 per cent solution, which is effective in the restoration of the sodium content of the blood, and (3) parenteral administration, if the foregoing methods are impossible. The intravenous and subcutaneous methods of treatment are not as effective as the oral route. If therapy is delayed, the condition is no longer reversible and may end fatally.

**Treatment of Meningococcic Infections by Artificial Fever.**—The morphologic and biologic similarity between gonococci and meningococci led Bennett and his associates to experiment with thermal death time studies of the latter organism. Their observations obtained so far by water bath studies indicate that these organisms likewise can be destroyed by heat which the body can safely tolerate. The meningococci seem to be very heat labile when first transplanted to broth mediums but become more heat resistant through each successive generation on a given medium. This phenomenon makes it difficult to set a standard death time for a specific strain. In general, however, the authors have been able to destroy most of the strains at 41.5 C. (106.8 F.) within eight hours. The extinction method for determination of thermal death time was used because it adapts itself to the effect of sustained heat at a given temperature for a definite length of time. Clinically, two patients with proved chronic meningococcic infection, one of whom had two attacks of meningitis, have been cured by artificial physical fever therapy without other therapeutic procedures. Further clinical trial of this method is recommended in subacute or chronic meningococcic infections, especially in cases of meningitis not responding to serum therapy. The authors feel that in the acute fulminating types of meningococcic meningitis fever therapy is contraindicated.

Common Foot Complaints. F. W. Carruthers, Little Rock.—p. 136.  
\*Insulin Protamine in Treatment of Diabetes. A. A. Blair, Fort Smith.—p. 139.

**Protamine Insulin in Treatment of Diabetes.**—Blair treated four cases with protamine insulin, each of which had been under careful management for from three to nine years. The ages ranged from 17 to 54 years. The slow action of protamine insulin can be partially overcome by using protamine insulin one hour before breakfast instead of the usual fifteen to twenty minute period allowed for the regular insulin. The fact that the diabetic patient is harder to keep sugar free in the morning than at any other time of the day indicates that the morning dose should always be relatively larger. A diet that contains plenty of fruit affords an easily utilized form of

blood pressure or the pulse rate. I should like to ask Dr. Smith whether he observed this phenomenon clinically.

DR. H. M. KEITH, Montreal: I was interested to hear Dr. Smith say that one cannot get convulsions by stimulating the sinus. I can confirm that from my own experience. I have been able to produce some slowing of the pulse, some drop in blood pressure, but no convulsive attacks.

DR. G. E. WAKERLIN, Louisville, Ky.: The carotid sinus and cardio-aortic areas contain chemical, as well as pressure, receptors. Have the authors studied the effect of reduction in the carbon dioxide and hydrogen ion concentrations of the blood, produced by overventilation for example, on the blood pressures of their patients to see whether a corresponding decrease can be brought about by such chemical changes?

DR. GÉZA DE TAKÁTS, Chicago: I have had experience with three patients in whom denervation of the carotid sinus has been done. One was operated on over two years ago, first on one side and then on the other six weeks later. There is no residual hypertension in these patients. The patient operated on two years ago is getting a recurrence of his symptoms. He is a man, aged 32, with no evidence of arteriosclerosis. It is possible that since it was my first denervation it was not as complete as it should have been. It is not enough to denervate the sinus but it is necessary to strip the carotids for 1 inch both above and below the bifurcation. It is possible that this failure is due to faulty technic.

DR. RICHARD CAPPS, Chicago: I should first like to confirm the remarks of Dr. Williams. I have seen complete asystole for as long as thirty seconds due to carotid sinus pressure. I believe that in some cases in which the reflex is unusually active the heart could be stopped for a long enough time to cause death, especially if a peripheral vasodilatation is also present. In the second place, I think that patients who have had coronary thromboses have particularly sensitive reflexes of this type. It is not unlikely that the increased sensitivity of the vagal reflex in the older group, discussed by Dr. Smith, is due to the heart's being more sensitive to vagal impulses than normally and not due to any change in the carotid sinus itself. As to the reason why the symptoms cannot always be correlated with the degree of slowing, I think the answer lies in the fact that there are three separate mechanisms which independently may cause identical attacks. First of all, slowing of the heart, in the second place reflex peripheral vasodilatation producing a fall in blood pressure, and third, the fact that there is a group of patients, particularly younger people (whom Weiss, Ferris and I recently investigated) in whom there is no change in the circulation at all; I mean there is no change in the blood pressure or pulse. We also measured the cerebral blood flow and found no change there. In this group we feel that the symptoms are probably due to direct nerve reflexes to the brain. In many of the older cases, in which bradycardia seems to be the cause of fainting, atropinization fails to alter the attacks produced by carotid sinus pressure, although it abolishes the reflex slowing of the heart. This demonstrates that a cerebral reflex may be present and primary but simply masked by the vagal reflex. I think that such combinations of reflexes account for some of the failures of therapy with belladonna. We found in most cases of the primary vagal type that a small dose of belladonna would diminish the reflex sufficiently so that no spontaneous attacks occurred. This, however, was not true in the group in which the cerebral reflex was the chief cause. One other point is that digitalis seems to increase distinctly the sensitivity of the vagal and cerebral reflex, and the attacks of faintness that many have seen in digitalized patients may be due to this cause.

DR. H. L. SMITH, Rochester, Minn.: It has been my experience that patients who have recently had an acute coronary thrombosis do have carotid sinuses that are hypersensitive, and I have further observed that most adults with congestive heart failure from any cause will have carotid sinuses that are more sensitive than normal individuals. In answer to Dr. Weisman's question as to whether the carotid sinus is fatigable, I have noticed that often rather long and continued pressure or often repeated stimulation causes the carotid sinus to become less sensitive. I suppose this feature could be due to fatigue. I have also noted that the sensitivity of the carotid sinus seems to

vary from time to time. Just why this is true, I am not able to explain. Dr. Williams asks the question "Is it dangerous to induce these attacks?" With proper technic I would answer no. I do not feel, however, that long continued pressure on both carotid sinuses at the same time is a sane practice. I have come to the conclusion that it is not necessary to stimulate the two sinuses at the same time. I doubt very much that one could produce death or do the individual any serious damage by stimulating one carotid sinus, even though we theoretically deprive the heart of its normal pacemaker and induce long periods of cardiac standstill. After cardiac standstill of certain lengths of time, the ventricles or bundle will initiate a rhythm of their own and will carry on the functions of the heart. In answer to Dr. Keith's question Were we able to induce the attacks in patients with epilepsy? I wish to say that we have examined many patients with idiopathic epilepsy and have not been able to reproduce these attacks. In no cases of epilepsy that we examined did we find the carotid sinus more sensitive than normal. In answer to the question What rôle does chemical stimulation play in producing these attacks? some investigators feel that chemical stimulation is an important factor in the carotid sinus reflex, but I have had no experience with chemical stimulation of the carotid sinus. I feel that there is still a great deal to be learned about this group of cases. I think that an advancement has been accomplished by definitely taking this group out of the class of epilepsy, in which class most of them had previously been considered.

#### The Pathogenesis of Experimental Hypertension Produced by Renal Ischemia

DR. HARRY GOLDBLATT, Cleveland: Exactly how the actual elevation of blood pressure due to renal ischemia is effected is not yet known. The possibility that the hypothetical pressor substance exerts its effect indirectly by some action on endocrine organs known to produce pressor substances, or by a synergistic action with such substances, is being investigated. Page has shown that hypophysectomy does not interfere with the development of this type of hypertension. Incomplete, too short and as yet too few experiments indicate that bilateral adrenalectomy does interfere with the phenomenon. The significance of this is not yet known. The whole study is being continued.

#### DISCUSSION

DR. WILBER E. POST, Chicago: This has been fascinating me since I first heard of Dr. Goldblatt's work, because so far as I know this is the first work in which hypertension is produced in which one might think that the damage is in the kidney alone and not in the generalized vascular system. For over twenty years I have been collecting histories and analyzing the medical story in patients who have died in uremia, trying to find those cases in which the kidney alone is damaged. The closest I have come to it has been in those cases, few in number, in which bilateral ureteral occlusion has resulted in permanent anuria. In those cases the blood pressure rose but slightly. Dr. Apfelbach did some work on dogs—I think it has been demonstrated before this society—in which he injected charcoal particles into the renal artery and thus was able to damage the kidneys, especially the glomeruli, which led to a degenerative process and ultimately to uremia, that is, renal failure, and yet in none of those dogs was he able to produce hypertension. It is with a great deal of interest that I shall follow this work of Dr. Goldblatt to see what may be revealed as the mechanism for the production of this hypertension.

#### Significance of Increased Blood Pressure in Pregnancy

DRS. JULIUS JENSEN and CARL WEGNER, St. Louis: Heretofore in cases of increased blood pressure in pregnancy, proper distinction has rarely been drawn between toxemia and hypertension. A closer study of this subject is revealing a close relation between the two. In pregnancy there is a distinct tendency for essential hypertension to become worse and remain worse. This is in line with certain physiologic knowledge regarding the effect of pregnancy on the cardiovascular system and also with Herrick's finding that the incidence of hypertensive heart disease is increased among women who have previously had eclampsia. This study concerns a follow-up examination of forty-nine women who had increased blood pressure during pregnancy. It was found that the tendency to increased

absent or greatly diminished in potency. By comparative tests made with serums from twenty healthy adults, the streptococidal action was not demonstrable. Three different strains of *Streptococcus haemolyticus* of the beta type were employed in the experiments. Differences in susceptibility of the strains to the killing power of the serum were noted.

**Factors That Influence Action of Human Serum on Hemolytic Streptococci.**—Tillett points out that, although serums derived from patients at the time of acute, active infection were found to be capable of destroying hemolytic streptococci under aerobic conditions, the organisms retained viability when the tests were performed anaerobically. Within the limitations of the experimental procedures that were employed, the aerobic or anaerobic effect was found to be a reversible reaction. Heating serums at 60 C. for one hour inactivated the streptococidal element in most instances but not in every case; heating at 56 C. for one hour impaired the lethal power of half of the specimens that were tested. Serums retained the capacity to destroy hemolytic streptococci when kept in the icebox for three weeks; a slight diminution in killing power was observed after four weeks.

**Treatment of Lung Abscess.**—To determine means of reducing the high mortality from lung abscess, Allen and Blackman present an analysis of 100 cases, in which the death rate was 34 per cent. For the first fifty patients it was 42 per cent and for the last fifty, all of whom were treated during the last five years, it was 26 per cent. Of the thirty-four patients who died, however, six died of carcinomas that were producing abscesses by obstruction. Of the remaining ninety-four cases therefore the mortality rate was 29.7 per cent. This reduced mortality is the result of the facts learned in the treatment of the earlier cases and from the experience of others. It may well be attributed to earlier diagnosis and institution of treatment, closer cooperation between the internist and the surgeon, more accurate localization, and the earlier institution of more radical treatment when conservative treatment has failed. With continued attention to this problem, further reduction in the mortality rate may be anticipated. Conservative treatment should not be continued unless progressive improvement is being accomplished, regardless of the time element. Phrenic nerve crushing is sufficiently valuable to make its use advisable in certain selected cases. Treatment by bronchoscopic drainage probably is for those abscesses which are caused by foreign bodies. Operative drainage should always be done in two stages. A wide area for drainage should be established. The drainage tract down to the abscess should be made with the actual cautery. Tube drainage of complicating empyema is of value when the patient's condition is so critical as to make a more radical operation too hazardous.

Medical Service in Vermont: Some Changes in Forty Years. L. W. Burbank, Cabot, Vt.—p. 1292.

**Signs of Active Rheumatic Fever.**—Massell and Jones base their remarks on a study of 178 patients with active rheumatic fever. In 163 of these cases an analysis has been made of the routine laboratory tests and a comparison made of the leukocyte count and erythrocyte sedimentation rate in respect to their value as tests for active rheumatic fever. Also the clinical manifestations have been analyzed in seventy-three patients with clinical evidence of rheumatic fever, and the relation of laboratory tests to the clinical signs has been determined. The leukocyte count and corrected sedimentation index are helpful and often essential for the determination of low grade rheumatic fever. In the majority of instances, after the clinical manifestations of the disease subsided, one or both of these tests continued at an elevated level for from several weeks to many months. As tests for low grade rheumatic fever, the corrected sedimentation index and leukocyte count are of about equal value. In view of the large percentage of error in the technic of the leukocyte count and the necessity for repeated counts, the corrected sedimentation index is more valuable as a single, isolated test. One or both tests may be normal in the presence of clinical signs of rheumatic fever. Corrected sedimentation index determinations are of no significance in the evaluation of active rheumatic fever if performed within two or three weeks after an infection of the upper part of the respiratory tract or tonsillectomy. Neither the leukocyte count nor the corrected sedimentation index is a specific rheumatic fever test but must be interpreted with regard to other considerations. In rheumatic fever subjects, repeatedly elevated leukocyte counts and rapid corrected sedimentation indexes should be considered indicative of subclinical rheumatic fever in the absence of any other cause for their abnormality.

**Scurvy in Etiology of Subdural Hematoma.**—In studying the incidence of chronic subdural hemorrhage as reported by various authors, Ingalls finds that it occurs primarily in infants, chronic drinkers and the insane. Subclinical scurvy may exist before clinical manifestations and x-ray changes of chronic subdural hemorrhage become apparent. In the group of nine infants studied at the Infants' and the Children's Hospital in Boston one is excluded, as it was an instance of birth hemorrhage. Five of the eight remaining patients were cared for in institutions or by foster mothers, and six were specifically recorded to have had rosaries of varying degrees. Roentgenograms of the long bones were available for study in five of these cases, and x-ray evidence of scurvy was elicited in three. Active scurvy could not be demonstrated readily in each patient since the essence of the conception is that of a chronic low-grade process. One might say that chronic subdural hemorrhage as encountered clinically and at necropsy is an end stage far removed from the initial series of events. The scurvy

**Ischemic Pain in Exercising Muscles.**—Elliot and Evans present observations which aim to test the hypothesis that lactic acid and the pain substance are identical. While a final answer cannot be given, it is shown that this hypothesis adequately explains the experimental results obtained and that at least production and disposal of both lactic acid and pain substance are subject to similar metabolic laws. Their conclusions are that: 1. The substance or substances responsible for pain in exercising ischemic muscles are relatively stable, may be present in the blood stream for an appreciable period following their release from such muscles, and may diffuse into tissues distant from their point of origin. 2. Such substance or substances are produced likewise in nonischemic exercising muscles, and their concentration in the blood stream following vigorous exercise is materially increased for an hour or longer. 3. Increase of lactate ion in the muscles of the forearm, brought about by whatever means, uniformly enhances the action of the pain substance produced by these same muscles. 4. Probably an increased concentration of lactate ion about the sensory nerve endings can by itself produce pain, such increase not necessarily exceeding metabolic limits. 5. It is possible that lactate ion is solely responsible for the production of ischemic pain, but release of other substances, which are beyond doubt subject to similar metabolic laws, may play a part, and these should be investigated.

**Roentgen Diagnosis of Carcinoma of Pancreas.**—Paul's review of twenty-three cases of carcinoma of the pancreas shows that, while a majority give some evidence of the pres-

ence of the neoplasm when studied by means of a barium sulfate meal, this evidence is often difficult to evaluate and may even be misleading. A smaller number (34.8 per cent in the present series) will give unequivocal results which will be found to be highly accurate. More careful observation and correlation of the cases here reviewed, at the time of the examination, would probably have led to a higher number of correct diagnoses. Since the diagnosis depends mainly on the secondary effects of the tumor on the stomach and duodenum, the degree of accuracy will not be nearly as high as it is, for instance, in gastric carcinoma. Errors in diagnosis seem unavoidable; not only will carcinoma of the pancreas be missed but other lesions will occasionally be interpreted as such. A statement of the positive observations and the conclusion that these are compatible with a mass in the region of the pancreas will be as much as the roentgenologist can safely conclude in most cases.

**Patient with Three Neoplasms.**—Portuondo cites a case of three dissimilar types of tumor. Two of these and a metastasis from the third were within the cranial cavity. The hypernephroma was in all probability an example of a cell rest becoming neoplastic. The acoustic neurofibroma may also have had its origin in a cell rest which became active. The peripheral areas of the neurofibroma contained many whorls of spindle shaped cells, while in the more central portions there were only a few in a stroma composed of cells having small round nuclei and a fusing of membranes to form a tenuous background. The carcinoma of the pituitary would seem to have no demonstrable relationship with any cell rest. From the history it appeared that the acoustic neurofibroma was of about four years' standing. Visual disturbances were marked a year and a half prior to death, which indicates that the pituitary tumor was large enough at that time to cause ocular signs and symptoms. The weakness, listlessness and hypotension may have been due to the hypernephroma, and, since these symptoms were of some five years' duration, it would seem that the kidney tumor had been present about that length of time. The cerebellar metastasis may have been responsible for the slow slurring speech and the staggering gait. These occurred only about two months prior to death, which would indicate that the metastasis may have occurred at that time, although it may have been present longer without causing enough destruction of cerebellar tissue to produce signs. The added presence of the hypophyseal carcinoma suggests a special tendency to neoplasms, and it may be that this was the decisive factor.

**Tuberculosis in Young Adults.**—Lloyd and Macpherson stress the fact that about four out of every five young adults suffering from pulmonary tuberculosis who have been in contact with a known case of infection develop the disease within five years of exposure to the last known contact. This demonstrates the value of continuing the observation of contacts for at least five years after they were known to be last exposed. There is a history of household infection in 82 per cent of the contact cases. History of exposure to tuberculous fathers is almost twice as frequent as history of exposure to tuberculous mothers. In about half of the contact cases spread of infection is not obviously due to transmission of the disease from parent to offspring, but in many cases infection is apparently introduced into the household by a brother or sister. About 60 per cent of the young adults who develop pulmonary tuberculosis are unaware of any contact with the infection. In noncontact cases the toxemic type of onset is more common than the nontoxemic (70 versus 28 per cent). If all classes of contact cases are taken together, the toxemic and nontoxemic types of onset occur in about equal proportions. It appears however that, if there is an interval of more than five years between the last known exposure to infection and the onset of the disease, the onset is more likely to be of the nontoxemic type.

**Renal Tuberculosis.**—Lett believes that better results can and will be obtained in renal tuberculosis if certain fundamental facts are widely appreciated and acted on: 1. The onset of renal tuberculosis is insidious and may be symptomless. Repeated examinations should therefore be made of the urine of every patient undergoing treatment for extra-urinary tuberculosis. If such examinations were carried out as a routine, many more cases of tuberculosis of the kidney would be recognized in their early stages. 2. Some cases of very early renal

tuberculosis can be cured by medical treatment, provided they are recognized before there is any alteration in the outline of the pelvis or calices. 3. Unilateral renal tuberculosis becomes surgical as soon as pyelograms show the changes characteristic of the disease, for it is then beyond the hope of cure by medical means alone. 4. The patient may be free from disturbing symptoms for prolonged periods, but the disease will almost invariably progress and ultimately prove fatal unless the kidney is removed. 5. Sanatorium treatment should always follow nephrectomy and in some cases precede it, for renal tuberculosis is not a primary disease; it is always secondary to a systemic infection and indicates a lowered resistance to the tubercle bacillus. Close cooperation of the general practitioner, the physician and the surgeon is more desirable and indeed essential in renal tuberculosis than in any other disease.

**Pyelitis and Pyelonephritis.**—Silvertown treated thirty-seven patients with various infections of the urinary tract by acidification or mandelates. Only vesical or posterior urethral infections were present in about one third of the patients. At the beginning of this work acidification alone, with strong nitrohydrochloric acid, was the method employed. The results were satisfactory in the majority of cases, but thorough eradication of the infection was made possible in some only by the addition of sodium mandelate or by the administration of ammonium mandelate instead. Seventeen patients were treated with strong nitrohydrochloric acid alone, success being complete in thirteen and partial in four; in three of the latter an organic lesion was present, while in the fourth the acidification caused severe irritation of the bladder. Nine patients were treated with ammonium mandelate alone, with success in seven and partial success in two. No organic lesions were present in this group of patients. Six patients were treated with strong nitrohydrochloric acid followed or accompanied by sodium mandelate, with partial success and success in two each. Only in the two successful cases were organic lesions absent. Five patients, to whom previous treatment with strong nitrohydrochloric acid had been given, were treated with ammonium mandelate. Treatment failed in one, was partially successful in two and was successful in two. It is concluded that hyperacidification of the urine is a powerful bacteriostatic or even bactericidal method. The addition of salts of mandelic acid reinforces this action. A combination of the two effects may be achieved in most cases by the use of ammonium mandelate, which both acidifies the urine and allows the excretion of mandelic acid.

the bones of the axial skeleton. The lesions usually occur in the ends of the long bones, most frequently in the femur. The midportion of the shaft, however, may be invaded. The process is primarily destructive and originates in the medulla. There may be varying degrees of expansion of the cortex, erosion of the cortex and periosteal proliferation. The picture may simulate a primary bone tumor, a bone cyst or an inflammatory process. The ribs and sternum are favorite sites for bone infiltration. The process in the sternum is usually destructive, but there may be bone proliferation and expansion. Only destructive changes in the bones of the skull have been observed. The areas are usually circular with sharply defined margins, but the borders may be irregular and ill defined. Frequently there is a soft tissue tumor directly overlying the area of destruction. The shoulder girdle is involved in a small percentage of cases. Bone involvement has usually been considered a late manifestation of the disease; however, in the authors' cases the bones were involved early in the course of the disease in nearly 25 per cent. Extension to the bone occurs by direct invasion from adjacent diseased nodes or by a metastatic dissemination presumably through the blood stream. A primary Hodgkin's disease of bone without involvement of lymph glands, spleen or liver has not been observed. The response of bone lesions to radiation treatment is exceedingly variable. Although striking regression of the disease is occasionally observed, the osseous foci are, on the whole, less radiosensitive than the glandular foci. The sternal cases have shown the most satisfactory response. Potentials of at least 200 kilovolts are superior to the lower voltages. Small divided daily exposures of from 200 to 300 roentgens (measured in air) with total doses of from 600 to 1,200 roentgens per port have been found to be fully as effective as larger doses, and this method possesses the advantage that the treatment may be repeated frequently. Relief of pain is very striking in many cases, and symptomatic improvement is frequently obtained even though there is no evidence of bone regeneration. Although much can be done in a palliative way, the prognosis is grave. The longest duration of life occurred in those patients presenting sternal tumors, four of whom lived five years or more.

**Recurrent Idiopathic Spontaneous Pneumothorax.**—Sycamore reports a case of recurrent idiopathic spontaneous pneumothorax of the relapsing type, with a pronounced tension pneumothorax in one attack. The emphysematous bulla, which was apparently the etiologic factor, was plainly visible on the roentgenogram. In only one of Kjaergaard's cases was the lesion demonstrable roentgenographically. The patient has had five attacks of spontaneous pneumothorax in three years. The presence in the pathologic specimen of fibrous tissue and anthracotic pigment and the absence of any bronchial structures justified a diagnosis of emphysematous bleb rather than solitary lung cyst. Operation was performed for the removal of the emphysematous bleb.

**Ulcerative Hodgkin's Disease of Skin.**—Seneor and Caro present a case of Hodgkin's disease with the ulcerative type of cutaneous lesion, which illustrates the difficulty of diagnosis

often presented by the ulcerative manifestations of Hodgkin's disease. Ulceration may be said to occur in Hodgkin's disease in three different ways. The first is the type in which there are a number of cutaneous or subcutaneous nodules showing the typical histopathologic structure, in some of which ulceration develops. In the second type the skin is affected as a result of involvement secondary to lymphogranulomatous changes in underlying structures. In the third form there develop in the skin, either as the primary manifestation of the disease, or subsequent to but not as a direct extension of glandular involvement, large infiltrates or tumors rather than the small nodules which characterize the first variety. In the second and the third types the ulcers are, as a rule, extensive. It is particularly with these larger ulcerations that the authors are concerned, because it is when they are present that the greatest confusion in differential diagnosis is likely to arise. This is particularly true in cases in which the infiltration and subsequent ulceration develop before an enlargement of the palpable lymph node areas is apparent. The ulcers usually develop and extend rapidly up to a certain point; then extension ceases or is slow. The number, form, size and location of the ulceration vary. As a rule the margins are elevated; often they show a somewhat padlike elevation. The margins may be undermined and flabby or sharply punched out to resemble a gumma. Usually the ulcers are deep and have an uneven floor covered with abundant purulent or necrotic material or granulation tissue. The base, as a rule, is soft. In most cases there is a fetid odor. In some cases the ulcers develop in a large plaque of infiltration, while in others they develop from the breaking down of underlying glands, after which an extensive infiltration of the tissues surrounding the ulcer may take place. In the present case this secondary infiltrate covered almost the entire right side of the chest. As a rule the ulcers bleed freely when touched. Pain of variable degree, at times severe, is usually present. The ulcers may simulate closely the lesions of syphilis, sarcoma, mycosis fungoides, epithelioma and tuberculosis.

**Calcium Metabolism in Scleroderma.**—Cornbleet and Struck have encountered eleven patients having scleroderma. They determined over an extended period the calcium and phosphorus balances in two patients in whom there was unquestionably definite retention of both calcium and phosphorus beyond the amount conceivably necessary for growth of bone. Probably much of the retained calcium was deposited in the skin and muscular tissue. The disturbance of calcium metabolism may be so severe in some cases as to cause transfer of calcium from the fixed stores of the body—the bones—to the soft tissues. Not all patients with scleroderma may show retention of calcium and phosphorus but, when all facts are considered, it seems reasonable to believe that retention of calcium may be a fairly general feature of the condition. Certainly all investigators seem to agree that the calcium metabolism is affected. Shortly after administration of large doses of vitamin D was begun in the two cases in which balance studies were made the amount of calcium in the urine increased greatly, while that of the feces remained relatively unchanged. This is the characteristic effect of massive doses of vitamin D. The low calcium content of the urine helps to account for the retention of the element, and the increase in the output is sufficient to explain the negative balance observed during treatment. This is merely a symptomatic treatment, for there is no evidence that scleroderma is a deficiency disease. Further, the doses of vitamin D (from 200,000 to 300,000 international units) used are far above those required for normal growth or calcification or for recovery from rickets. From the clinical and chemical results in the eleven cases it seems fair to say that the abnormal calcium deposits in the skin were reduced by the vitamin D therapy before any appreciable amount of calcium was removed from the bones. A hypothesis is offered: that scleroderma is initially due to a toxin which injures the collagen syncytium and that these injured tissues secondarily take up calcium. This deposition of calcium may account for the frequently observed positive balance in scleroderma. Massive doses of vitamin D produce a negative balance, apparently at the expense of the calcium deposited in the collagen and muscle.

 Pancreas Diseases in Children. B. Benassi.—p. 728.

**Changes of Gastric Chemistry in Anemic Children.**—Racugno studied the behavior of the gastric chemistry in children suffering from infantile erythroleukemic myelosis and erythroblastic anemia of Cooley's type with osteoporosis. Hypo-achylia or complete achylia is a constant occurrence in all children suffering from erythroleukemic myelosis. It does not mean, however, that there is any relation between pernicious anemia in adults and anemia of erythroleukemic myelosis. Megaloblasts or megalocytes are rarely or never present in the blood and the bone marrow of erythroleukemic children. Administration of liver and gastric extracts as well as of meat digested by normal gastric juice fails to give satisfactory results in erythroleukemic myelosis. Necropsies on children who have died from the disease fail to show atrophy of the gastric mucosa. According to the author, gastric achylia in erythroleukemia myelosis is secondary to hematopoietic alterations induced by the disease. In anemia of Cooley's type the changes of the gastric chemistry are less grave and less important than those induced by erythroleukemic anemia. Because of the different behavior of the gastric chemistry in the two types of anemia and of the familial and racial conditions that are necessary for the development of anemia of Cooley's type, the author advises taking Cooley's anemia out of the group of erythroleukemic myeloses of children. The changes of the gastric chemistry in several diseases of children complicated by secondary anemia are also induced by anemia.

**Arneth's Formula in Chronic Lead Poisoning.**—Guareschi studied the behavior of Arneth's formula in the blood of rabbits slowly poisoned by injections of an aqueous solution of neutral lead acetate. The most constant and obvious change in the blood picture was the shift to the left of Arneth's formula, followed late in the experiment by slight hypochromic anemia, leukocytosis and changes of the leukocyte formula. The forms of granulocytes that appeared in the blood of the animals early in the experiment were neutrophil myelocytes and metamyelocytes, which normally are found only in the bone marrow and which appear in the blood only in the presence of toxic or pathologic conditions by which the functions of the bone marrow are altered. Myelocytes, reticulo-endothelial cells and degenerated polynucleated neutrophils caused the shift of Arneth's formula to the left. The latter is not a specific manifestation of chronic lead poisoning. It is caused by a reaction of the organism to toxic pathologic stimulation of the hematopoietic myeloid and reticulo-endothelial systems. It can be induced by stimulation of the systems by toxic substances other than lead as well as by pathologic conditions. According to the author the shift of Arneth's formula to the left, in association with the presence of myelocytes in the blood, is of value in the early diagnosis of chronic lead poisoning.

 Luteinizing Factor of Anterior Pituitary-like Principle and Menstruation. F. P. Doneddu.—p. 561.

**Comparison of Meinicke Reaction and Schlessmann's Modification in Gonorrhea.**—Ambrogio made a comparative study of the diagnostic value of Meinicke's second clarification

reaction and Schlessmann's modification in gonorrhea. Both tests are of simple technic. The author found that Meinicke's second clarification reaction is of less value than the bacteriologic and clinical examinations in the simple acute forms of male gonorrhea and of greater value in the chronic forms without complications. A fairly good proportion of positive results (68 per cent) is obtained in genital and extragenital complicated cases. Nevertheless, negative results are obtained in cases of gonorrhea proved by local and general reactions. The Meinicke reaction gives a low proportion of positive results in female gonorrhea located at the cervical canal (64 per cent) and a high proportion in urethral gonorrhea and in gonorrheal Bartholinitis (90 and 75 per cent, respectively). Meinicke's reaction cannot be used for the diagnosis of gonorrhea in cases of syphilis when the syphilitic reaction is partially positive, because of the fact that its behavior is analogous to that of the syphilitic test. The control tests carried out by the author on serums from a group of nonsyphilitic persons, including normal persons and patients who had no venereal or gonorrheal genital diseases, showed that Meinicke's reaction gives a great percentage of nonspecific results, which may be made positive after the patients receive injections of specific vaccine or of nonspecific proteins. Schlessmann's modification of Meinicke's reaction generally gives results similar to those given by the original test. In some cases, however, the results of the tests do not coincide. Schlessmann's test is less sensitive but much more specific than the original test. Both technics are more sensitive than the complement fixation test but are not as specific as the latter. This fact and the lack of constant results of the original and modified Meinicke tests in different clinical types of gonorrhea rob these technics of their value in the serodiagnosis of gonorrhea.

**Diminution of Toxicity of Arsphenamine.**—De Luca made experiments on rabbits with intravenous injections of arsphenamine with and without skin extract. He concludes that the addition of skin extract to arsphenamine renders the latter less toxic to the rabbit. The detoxifying action is the same as that of liver and brain extracts. According to the author, the action of the skin extract is due to a condensation process between the molecule of arsphenamine and that of the amino acids present in the skin. The combination of the arsphenamine and amino acid molecules results in the formation of a molecular complex which has a less harmful effect on the tissues than that of the arsphenamine molecule alone. In the chemico-physical process amino acids are of importance, regardless of the organ from which they are obtained. There are slight differences in the neutralizing power of the extracts from different organs, probably because of the amount and quality of amino acids present in the given organ from which the extract is made.

**Treatment of Hemoptysis by Poison of *Vipera Russellii*.**—Raimondi and Sangiovanni state that the poison of the *Russellii* snake has coagulating properties, which are shown immediately after an intradermic injection of the poison and which are more obvious after two hours. The coagulation

carbohydrate and is quite an advantage at noon to check the gradual fall in the blood sugar when fairly large doses of protamine insulin are used early in the morning. A lower and more uniform blood sugar curve can be maintained with protamine insulin. The slow breakdown and absorption over a period of twelve hours should be borne in mind and the new preparation not recommended in preference to regular insulin in diabetic coma. However, the knowledge of its delayed absorption should relieve the patient from the mid-night dose of insulin, virtually doing with two doses of protamine insulin what was expected of four doses of regular insulin and at the same time avoiding sharp breaks in the blood sugar curve.

### Method for Detecting Staphylococcus Enterotoxin.—

Dolman and his colleagues report the suitability of kittens as test animals for the detection of enterotoxin, or the food poisoning substance, in staphylococcus filtrates. As little as 0.5 cc. intraperitoneally of a potent filtrate will cause a severe reaction in a kitten weighing from 350 to 550 Gm. and from 6 to 8 weeks of age, while 3 cc. of filtrate from innocuous strains, or of broth treated with formaldehyde, will occasion no upset. Adult cats may be used for the test, but they are harder to handle and seem relatively less sensitive than kittens.

### Surgical Aspects of Hematuria.—

Balch and Wishard state that a painless hematuria is dangerous and often means that a malignant condition is present. The entire ureter as well as the kidney should be removed in papillary tumors of the renal pelvis. Pyelolithotomy gives a 1 and nephrolithotomy a 10 per cent mortality. Hematuria associated with pyuria means renal tuberculosis until proved otherwise. About 95 per cent get well without surgical intervention. The exact cause of bleeding should be investigated in all instances of gross hematuria. Cases of bladder hemorrhage may be classified into those of slight severity in which orderly urologic examination may be done at an elective time and those of severe

bleeding demanding immediate attention. In nontraumatic bladder bleeding, treatment consists of emptying the bladder of clots and stopping hemorrhage, dealing with the underlying disease at a more opportune time if possible. In traumatic bleeding the bladder must be drained surgically if rupture is present. Contusion of the bladder without break of its walls may at times be treated by evacuation of clots and indwelling catheter drainage.

**Hemolytic Streptococci Isolated from Throats.**—Teiger and Seegal compared certain biologic and immunologic characteristics of sixty-three strains of hemolytic streptococci isolated from residents of New Orleans with 103 strains isolated in New York City. The New Orleans strains came from cases of acute nephritis and acute infection of the upper respiratory tract and from normal throats. The New York strains came from cases of acute nephritis and chronic or healed nephritis, with or without acute pharyngitis. The organisms were examined for their fermentation of lactose, mannitol and salicin, their hemolysis in blood pour plates, their production of a soluble hemolysin and skin toxin, their hydrolysis of sodium hippurate and their final  $pH$  in dextrose broth. Their membership in group A of Lancefield also was determined. By these tests no difference was found between the hemolytic streptococci isolated from the throats of individuals residing in New Orleans or in New York.

### Action of Human Serum on Hemolytic Streptococci.—

Tillett discovered that serums obtained from patients at the time of acute active infections were bactericidal for hemolytic streptococci in every instance. The observations were made with serums from twenty-five patients. The group consisted of cases of pneumococcus, hemolytic streptococcus, staphylococcus, meningococcus, tubercle bacillus and malarial infections; the etiology of the diseases in other patients was either uncertain or may have been a mixed infection. In serums taken from the same group of patients, soon after recovery or marked improvement had taken place, the streptococcal property was

opment of colds and of influenza, pointing out that in the case of colds the weather conditions play a more important part than in the case of influenza. Then he analyzes the rôle of constitutional factors in the pathogenesis of colds and again shows that their importance is not so great in influenza. On the contrary, strong and otherwise healthy persons frequently develop severe forms of influenza, whereas patients with tuberculosis, for instance, seem to have a considerable amount of immunity against it. As symptoms that are especially important for the differentiation of influenza the author mentions severe prostration at the onset, apathy, severe headaches, pains in the joints and, especially, circulatory disturbances in the form of an accelerated small pulse and slight cyanosis of the lips and of the finger nails. After mentioning the complications and sequels of influenza, he points out that the bacteriologic differentiation presents considerable difficulties, particularly for the practitioner. Nevertheless he thinks that colds and influenza should be differentiated as much as possible.

**Feeling of Oppression in Cardiac Insufficiency.**—Budelmann directs attention to a causal factor of the feeling of oppression in patients with myocardial insufficiency which, although known, is given little attention in daily practice. He shows that, in cases in which an insufficiency of the left side of the heart exists, pulmonary stasis is usually the eliciting factor of the feeling of oppression and of dyspnea. The mechanical modification of the respiration that results from the "pulmonary rigidity" plays an important part, but this factor is frequently disregarded in the treatment; the author discusses these conditions. He demonstrates that the determination of the vital capacity of the lung indicates the degree of pulmonary stasis. The "pulmonary rigidity" resulting from a reduction in the elasticity of the lung makes the respiratory mechanism more difficult and causes an increase in the intrapleural pressure. There is a close connection between pulmonary stasis and increase in intrapleural pressure, on the one hand, and the feeling of oppression and dyspnea, on the other. In the treatment it is important to improve the functional capacity of the heart and to prevent the overburdening of the heart in the form of an increased backflow. In an acute attack of cardiac oppression and dyspnea, it is moreover necessary to reduce the pulmonary stasis and with it the increasing intrapleural pressure. Pulmonary stasis is most effectively counteracted by venesection, provided a sufficiently large quantity of blood (from 700 to 1,000 cc.) is withdrawn. A pleural exudate should be carefully drained. In order to improve the functional capacity of the heart, strophanthin or digitalis should be given. In most cases the author found ineffective many of the medicaments that are ordinarily prescribed for cardiac oppression and dyspnea, such as camphor, caffeine, amyl nitrite, glyceryl trinitrate and oxygen. Regarding the prophylaxis, he says that all measures which prevent an overburdening of the water exchange have preventive value.

**Malariotherapy in Epidemic Poliomyelitis.**—In an epidemic of poliomyelitis, Kauders observed an unusually large percentage of adult patients and points out that in these cases the prognosis is usually less favorable than in children and young persons. In the surviving patients with paralysis, monoplegias were rare, the majority having extensive forms of paralysis. Most frequent was the complete paralysis of the lower extremities, frequently with involvement of the abdominal and pelvic muscles. The treatment of the acute poliomyelitis consisted generally in the administration of convalescent serum that had been obtained in this epidemic. Following the acute stage the paralytic parts of the organism were subjected to intensive after-treatment in the form of massage, electrical treatment, passive and active exercises, diathermy and so on. As these measures proved ineffective in many cases of severe paralysis, the author decided to try malariotherapy. After

citing the factors that induced him to resort to this measure, he gives a tabular report of eighteen cases. The table indicates that the number of malarial attacks varied between four and ten. The time of the beginning of the malarial treatment varied between sixteen and 103 days after onset of the disease. In discussing the results of the treatment, the author points out that the time is too short to permit a final evaluation, but the tabular report indicates that all patients were somewhat improved and that in five cases the results were excellent. He concludes that malariotherapy is an important therapeutic aid in the paralytic sequels of poliomyelitis.

**Erythrocyte Sedimentation Speed in Malignant Tumors.**—Reichel describes his technic of the sedimentation reaction and then discusses the factors that influence it. He points out that the sedimentation is not a reaction of the malignancy of a tumor but merely the manifestation of the resorption capacity for inflammatory and necrotic products. If the tumor itself has reached a certain size, it becomes readily necrotic. Moreover, the tumor often ulcerates and thus may cause infection of its own and of surrounding tissues. Then it may close excretory ducts, and the resulting stasis readily leads to infection. In these ways a malignant tumor leads to an acceleration of the sedimentation speed. As a nonspecific reaction, the sedimentation alone cannot be the basis of the diagnosis of a malignant tumor. However, since it is accelerated in 90 per cent of malignant tumors, a normal sedimentation speed in a doubtful case excludes a malignant tumor with considerable certainty. On the other hand, an acceleration of the sedimentation speed often directs attention to the presence of a malignant tumor.

**Blood Transfusion Therapy of Scarlet Fever.**—Ninety-three patients suffering from scarlet fever were treated by Zuykov and his associates with blood transfusions. In the majority of the cases the blood was taken from donors who had not had scarlet fever. The transfusion was performed in the early stage of the disease, between the second and fifth days. The amount varied between 100 and 300 cc., depending on the age of the patient. In sixty-one of the cases the transfusion aborted abruptly the course of the disease. From six to ten hours after the transfusion the temperature fell to normal, and the manifestations of intoxication and the inflammatory process in the throat showed a pronounced improvement. Convalescence took place two or three days later. Considerable improvement was noted in twenty-four cases. The temperature came down and the course of the disease became milder. In eight cases in which there were complications, the blood transfusion did not give a therapeutic effect. A strong reaction to transfusion was exhibited by six gravely sick patients. Following the transfusion there was a rapid and persistent fall of temperature. The therapeutic effect was best in patients in whom the toxic manifestations predominated over the inflammatory. This therapy gave a more permanent and a more pronounced therapeutic effect than the antitoxin-serum therapy. The authors believe that blood transfusion in scarlet fever acts as a nonspecific irritant and that colloïdoclasis was the basis of it. Blood transfusion does not safeguard against complications resulting from the action of streptococci accompanying the infection. The authors recommend the employment of blood transfusion in all severe cases of scarlet fever, especially the toxic and malignant varieties. In order to be successful the transfusion should be performed in the early stage of the disease and the citrated blood utilized should not be more than twenty-four hours old. The authors likewise obtained equally good therapeutic effects in thirteen cases of moderately severe scarlet fever in which small doses (from 0.25 to 0.5 cc.) of cytotoxic antireticular serum were administered.

process itself may have been arrested, without obviating the effects of repeated cerebral hemorrhage. It is not unreasonable to assume that close scrutiny of the dietary of alcoholic addicts and the insane would often reveal deficiency of vitamin C, an observation so much more subject to objective proof in early life. Cevitamic acid levels in the blood and urine studies for the determination of the degree of saturation with the vitamin offer new methods of investigating latent scurvy. The following sequence of events seems to be concerned with the production of idiopathic chronic subdural hematoma: An underlying bleeding diathesis is postulated in most cases on the basis of scurvy. Free subdural bleeding is produced by a definite or insignificant head trauma causing either disruption of arachnoid invaginations into the dural sinuses or rupture of a bridging vein. Organization and removal of the clot are impeded by the scorbutic process, resulting in a neomembrane surrounding free blood. Repeated trauma and remission and exacerbation of the scurvy modify the disease. Late symptomatology is occasioned by enlargement of the semipermeable sac following the slow breakdown of red blood cells and reduction of free hemoglobin into smaller molecular aggregates with the passage of time.

**Hodgkin's Disease with Bone Manifestations.**—Schenck points out that although it is well known that Hodgkin's granuloma is manifested by an enlargement of the lymph nodes and by an invasion of the lymphatic system, frequently associated with splenomegaly, it is not generally appreciated that the disease may also reveal itself in the skeletal system. The granulomatous invasion of the osseous structures, with or without visual or palpable lymph node involvement, is not a rare occurrence. The author considers only those patients who present roentgen evidence of bone changes in the clinical course of their disorder. In reviewing the records at the Jewish Hospital for the last ten years, he has collected 107 cases of Hodgkin's granuloma. In the first five years of the series, during which time there were twenty-three confirmed cases of lymphogranulomatosis, only one patient had skeletal involvement. In the last five years, which included fifty-nine proved cases, there were seven with osseous invasion, demonstrable roentgenologically. This discrepancy between the first and second periods is evidently due to the fact that bone lesions have been searched for and recognized more frequently in recent years. In this series of eight cases the vertebrae were involved in six, the pelvis in five, the skull in three, the femur in two, and the sternum, humerus, scapula and ribs in one case each. Larger series by other investigators have shown that the order of frequency of bone involvement is vertebrae, sternum, pelvis, femur, ribs, skull, humerus, scapula and clavicle. Two of the eight patients gave no history of pain over the involved region; in the others, pain, which was of a dull aching or sharp lancinating character, preceded the demonstrable invasion of the bone by a few days or as long as two years, as occurred in one case. With vertebral involvement the pains are often girdling in character and increased on motion. With involvement of the lumbar spine, the pains are frequently referred to the lower extremity. The other symptoms are the same as in Hodgkin's disease without bone changes.

Thus bone changes, especially when associated with the chief symptoms of the disease, should lead to the correct diagnosis. The advisability for more frequent and complete roentgen studies of the bones in Hodgkin's granuloma is obvious.

**Multiple Myeloma.**—Walker and Bloom present five cases of multiple myeloma and stress the protean manifestations of the disease. Clinically, myeloma cases present a varied picture. They are often diagnosed as neuritis, lumbago, arthritis, anemia, chronic nephritis and spinal cord tumors. Yet, when the widespread pathologic changes and the rarity of the disease are considered, these errors in diagnosis are explained and are to be expected. In almost all cases, pain is a prominent feature. The pain may be intermittent, severe, wandering or recurrent. Pathologic fractures are frequent and thoracic deformity is common. Chronic bronchitis and emphysema are often present. Owing to the fact that the tumor most frequently attacks the vertebrae, ribs and skull, neurologic symptoms and signs are common. The mental faculties remain clear, although as a terminal event mental confusion and coma do occur. The renal changes are variable. Clinically, the patient may present a picture of chronic nephritis with urinary changes in keeping with this diagnosis. There are no gastrointestinal symptoms that are peculiar to this disease, nausea, vomiting and colicky pains being the most common complaints. Therefore it is obvious that there is no symptom complex that is characteristic of myeloma. Only by the presence of some unusual physical phenomenon is the correct diagnosis suspected, this usually being confirmed by roentgenography and pathologic studies. Since multiple myeloma is primarily a bone marrow tumor, one would expect many changes in the blood. All osteolytic bone lesions have to be excluded. Metastatic carcinoma and metastatic hypernephroma particularly have to be ruled out. Chloroma and bone cysts are sometimes confusing. There are no physical or laboratory observations that can be absolutely depended on to make a differential diagnosis, and for absolute proof of the existence of this disease a biopsy is necessary. The prognosis is unfavorable. Roentgen therapy brings about remissions, although these may occur spontaneously; but no proved case has ever been reported as cured. The average duration of life is about three years.

well. Certainly the crisis that accompanies abortive pneumonia, often on the second or third day of the disease, is just as dramatic as the natural crisis which occurs on the seventh or eighth day in those who receive no serum. All physicians can recall acutely ill pneumonia patients who, on the morning after receiving serum, insist on telephoning their offices or reading the morning newspaper.

Chart 1.—Septic type I pneumonia treated on first day of disease with concentrated antipneumococcus serum. Upper line, temperature; lower line, bacteremia.

One of the most interesting methods of studying the effect of antipneumococcus serum on the pneumonic process is to take daily roentgenograms during the active period of the disease. By this method of study it can be shown that the prompt and adequate administration of serum usually limits the infection to one lobe. If serum is given very early, the area of infection in the involved lobe is sharply demarcated and rapidly fades out. When serum is started a little later, from twenty-four to forty-eight hours after onset, it often happens, as pointed out by several observers, that though an immediate crisis is induced, the area of consolidation in the involved lobe increases somewhat in size and may finally involve the entire lobe.

Numerous writers have stressed the value of antipneumococcus serum in preventing or checking bacteremia. Even when serum is given late in the disease, a heavy blood stream infection is often overcome, though a fatal termination may ensue. When bacteremia develops early in the disease, it is promptly eliminated by serum therapy. This is well illustrated in charts 1 and 3.

Chart 2 illustrates the effect of early serum therapy on bacteremia in two monkeys that were given lethal doses of pneumococcus type I culture intratracheally.<sup>3</sup> Both animals rapidly developed the classic signs of lobar pneumonia accompanied by bacteremia. Pneu-

mococci promptly disappeared from the blood stream after the first injection of type I antipneumococcus serum.

The mechanism of this phenomenon is fairly well understood. The pneumococci, apparently, are agglutinated by the serum and are filtered out of the blood as it passes through the liver and spleen.

One of the earliest reactions to pneumococcal infection of the lungs is a leukocytosis, preceded in some cases by a fleeting leukopenia. This leukocytosis is due almost entirely to an increase in the number of polymorphonuclear leukocytes. In man the total count is usually between 15,000 and 25,000 with the polymorphonuclears ranging from 80 to 90 per cent. In exceptional cases the leukopenia persists, while in still others the count may go to 40,000 or more. In experimental animals, the same leukocytic response is observed. In monkeys this leukocytic response is sometimes quite marked. (This is well illustrated in chart 2.) Schilling counts reveal a sharp increase in the percentage of immature white cells in the blood. When antipneumococcus serum is administered early in the disease and localizes the pneumococcal infection in the lung, there is usually a prompt drop in the polymorphonuclears. With this drop there is an accompanying fall in the percentage of immature cells and a sharp increase in the number of monocytes.

Dochez<sup>4</sup> showed that at the time of the natural crisis in pneumonia the so-called protective bodies first make their appearance in the circulating blood. In numerous instances during studies at Bellevue Hospital, the prompt appearance of protective bodies in the serum of pneumonia patients who had been early and adequately treated with serum has been demonstrated

Chart 2.—Abortive type I pneumonia in monkeys, produced by early and intensive serum therapy. Upper solid line, temperature; lower solid line, leukocytes; broken line, bacteremia.

(chart 3). Bullowa<sup>5</sup> has demonstrated homologous agglutinins in the blood of pneumonia patients after treatment with specific serum and has made practical use of this test for determining when the patient has had a sufficient quantity of serum. The precipitins run

Precise Aortometry. S. Kreuzfuchs.—p. 2013.

**Fifteen Minute Phenolsulfonphthalein Test.**—Vallery-Radot and his co-workers studied the possibility of substituting a shorter period than the classic one in the use of the phenolsulfonphthalein test. Their investigations were made on eighty-one subjects, of whom six were completely normal and seventy-five had various diseases, particularly hypertension, Bright's disease and old nephritis. The phenolsulfonphthalein test was performed according to the classic method, a period of one hour and one of fifteen minutes being used. The technic was approximately the usual one, with intravenous injection of 1 cc. of a solution containing exactly 6 mg. of phenolsulfonphthalein. As far as possible, the urines were collected by spontaneous micturition a quarter hour, a half hour, one hour and two hours after the injection. In the six normal subjects they found that the test gave a volume excretion of more than 25 per cent of the dye at the end of a quarter hour and of more than 65 per cent at the end of an hour. The other patients were divided into three groups. In thirty-one there was an elimination greater than 25 per cent in the first quarter hour. In the majority of these the functional integrity of the kidneys was confirmed by other tests. In thirty-six subjects the elimination was only 15 per cent or less in the first quarter hour. This result was paralleled by the excretion in one and two hours. Finally, eight of the patients had an excretion of between 17.5 and 22.5 per cent in the first quarter hour. These results led to the conclusion that an elimination of phenolsulfonphthalein equal to or higher than 25 per cent in a quarter of an hour indicates that elimination in one hour or longer will surely be normal. An elimination of less than 15 per cent in a quarter of an hour indicates similarly a defective elimination over a longer period. No conclusions can be drawn from elimination in the neighborhood of 20 per cent in the first quarter hour. Therefore the authors believe that it is sufficient to shorten the test to a quarter of an hour, which, since it is equally accurate, is more rapid and more sensible than the more prolonged periods.

Clinical Study of Use of Drugs with Purine Base. J. Schunck de Goldfiem.—p. 2038.

**Hypo-Amphotonic Method with Atropine.**—Little attention has been paid to the so-called hypo-amphotonic action of atropine, when given in long-continued doses, on both the sympathetic and parasympathetic nervous systems. According to Daniélopou and Radulesco, this action is entirely different from the common clinical treatment of disease with atropine. The method used by these authors is based on the paralyzing action of atropine on both systems when given for prolonged periods. They have proved that small doses of atropine excite the sympathetic and parasympathetic, but predominantly the latter. Average doses currently employed in therapeutics and administered at one time exert a paralyzing action on the parasympathetic exclusively. Large and toxic doses have both a direct action on the tissues and a vegetative effect. It is, however, with the use of small doses over long periods that the authors are particularly concerned. Classic treatment is employed in unaccustomed subjects, while their method is based on habituation to atropine. Classic treatment results in three phases: excitation, paralysis of the parasympathetic and excitation. Furthermore, the classic treatment is aimed at recovery, while their method is preventive. Usually they began treatment by giving a daily dose of 1 mg. of atropine sulfate administered in three doses. This is increased by 0.5 mg. daily until 3 or 4 mg. is given daily, always in three doses. The top dose is continued as long as necessary. Intolerance is judged by the heart rate, which, when the drug is properly given, is not accelerated by the treatment. Except in rare cases, it is

admirably supported. This treatment is indicated in so-called vagotonia, seasickness, asthma, ulcer of the stomach, biliary colic, tabetic gastric crises, toxic goiter, angina pectoris, muscular hypertonia, severe vomiting of pregnancy and preanesthetic preparation of patients. The wide range of usefulness is due to the double action of atropine when given in this manner, and it deserves a place in the treatment of a considerable number of disorders.

**Courtois Sign in Coma Due to Cerebral Lesion.**—Sivadon calls attention to the sign described by the late Adolphe Courtois for helping in the localization of circumscribed cerebral lesions in the presence of coma. It consists in the following: The comatose patient is placed on his back; flexion of the head on the chest produces in only one region an automatic flexion of the leg on the thigh and the thigh on the abdomen; this movement is strictly unilateral, and on the side on which the anatomic examination revealed a localized lesion of the cerebral centers which had produced the comatose state. The two cases on which this sign is based are redescribed by Sivadon. In one of them necropsy confirmed the localization indicated by the sign.

Diagnostic Value of Henry's Reaction in Obstetrics and Gynecology. Marie Reniger-Areschian.—p. 934.

**Complications of Radium Therapy in Gynecology.**—The use of radium in gynecology can cause complications through its direct action or through the inflammatory process caused or revived by the radium. Reiles and Fobe state that the most common direct actions are the development of uterine perforations, vesical fistulas, proctitis, cystitis and vaginal atresia. In Strasbourg, radium is used chiefly for three general conditions; namely, climacteric metrorrhagia, cancer of the cervix and cancer of the uterine body. It is important that in using this treatment the duration of application be carefully controlled and that the cervix be as free from infection as possible. The authors recommend as helpful in the majority of patients the injection of antiseptics a few days before the application of radium; sometimes vaccination and electrocoagulation would do much to decrease the risk from infection. The most important complication, however, is fatal pulmonary embolism, which they observed in 1 per cent of their cases of metrorrhagia, 1 per cent of those with cancer of the cervix and 28.5 per cent of those with cancer of the uterine body. The inflammatory complications can be decreased in frequency by the supplementary precautions outlined.

**Barium Sulfate in Gastric Hyperacidity.**—Finkelstein reports twenty-six cases of gastric hyperacidity and phenomena indicative of spastic colitis, which were treated by means of inert colloidal barium sulfate. In all these cases, which were characterized by spastic states of the digestive tube, the results were favorable. The therapeutic activity of the product is shown to be effective and lasting. It is more effective, however, in the presence of normal or increased gastric acidity than when the acidity is low or absent. The dosage varied from a teaspoonful to a soup spoonful before meals.

man, aged 60, originally an alcoholic, who later became a confirmed veronal (barbital) addict. His general health was very poor at the time he had pneumonia. He received 150,000 units of type I serum.

The other fatality occurred in the group of twenty-seven cases collected from the pneumonia records at Bellevue Hospital. The patient was 44 years of age and also chronically addicted to alcohol. On admission his leukocyte count was only 6,000 cells. For some reason he received only 52,000 units of type I serum, not nearly enough for a patient who was obviously a poor risk. He died on the fourth day of the disease.

In table 2 I have collected from the sources mentioned 160 cases of type I pneumonia in which serum was administered during the first twenty-four hours of the disease. In this series there were eight deaths, a mortality rate of only 5.0 per cent, one-third the death rate for all serum-treated cases, one-sixth the standard death rate for non-serum treated cases. These figures are certainly impressive, but no more so than the twenty-five cases of type I pneumonia recently reported by Abernethy,<sup>8</sup> who were treated comparatively early with concentrated serum at the Hospital of the Rockefeller Institute. There was not a single death in Abernethy's series, and none of the patients developed empyema or other serious complications.

Results such as these furnish much food for thought. Physicians who are interested in public health can now visualize the ultimate control of pneumonia, for there is every reason to believe that what has already been accomplished with type I serum can be achieved with the other types as well. It is true that type III pneumonia presents certain difficulties, but figures are already at hand which show that types II, V, VII, VIII and XIV are amenable to serum therapy. No doubt, in the course of time, investigators will be able to demonstrate for the other types of pneumonia what can now be proved for type I, namely, that the early and adequate use of antipneumococcus serum reduces pneumonia to a comparatively mild infection.

Finally, when one considers that serum is now available for approximately 65 per cent of all pneumococcal pneumonias, one cannot fail to be impressed with the great gap that exists today between what could be done and what is being done for the pneumonia patient. Herein lies the reason for the campaign for the control of pneumonia that is now being conducted in New York State.

#### SUMMARY

When patients with pneumococcus type I pneumonia are treated very early with homologous serum, the following phenomena are usually observed:

1. The disease may be completely aborted, the temperature and the pulse and respiration rate dropping to normal within twelve to twenty-four hours after the administration of serum.
2. There is striking improvement in the patient's general condition, as the result of the disappearance of toxemia.
3. Early serum treatment prevents the spread of infection from one lobe to another and even limits the area of infection in the lobe primarily infected.
4. Bacteremia is prevented or, if already present, is quickly checked.
5. The leukocytes rapidly return to normal.

6. Homologous agglutinins, precipitins and protective bodies promptly make their appearance in the circulating blood.

7. Skin tests become positive to the homologous polysaccharide.

8. The death rate is cut to approximately one-sixth the standard death rate for untreated type I pneumonia.

9. These conclusions are derived from studies on type I pneumonia, but evidence is rapidly accumulating that they apply with equal validity to several other types as well.

#### THE SIGNIFICANCE OF SEROLOGIC TYPES AMONG MENINGOCOCCI

SARA E. BRANHAM, PH.D., M.D.  
Senior Bacteriologist, National Institute of Health,  
United States Public Health Service  
WASHINGTON, D. C.

Meningococci form a single species, well defined, the members of which fall into broad serologic groups. The recognition of serologic differences by Dopter,<sup>1</sup> Arkwright,<sup>2</sup> Lieberknecht,<sup>3</sup> Trautmann and Fromme<sup>4</sup> and Elser and Huntoon<sup>5</sup> in 1909 paved the way for the intensive work that followed and resulted in the classifications of meningococci into serologic types, which were reported during 1915-1918. At this time it was generally recognized that there were two main groups, which overlapped to some extent. They were called 1 and 2 by the English workers and A and B by the French. By absorption of agglutinins these were further divided by Gordon and Murray<sup>6</sup> into four types, 1 becoming I and III, 2 becoming II and IV. French workers<sup>7</sup> found two other groups, C and D, which were uncommon. Meanwhile other classifications had been developed elsewhere, including the bacteriotropin classification of Evans,<sup>8</sup> which was on an entirely different basis. The relationship of these different classifications to one another is shown in table 1.

The four-type classification of Gordon and Murray has come into use in all the English speaking countries, while the broader A and B groups are more commonly recognized elsewhere.

During the years since these 1915-1918 classifications, most of the work on distribution of types of meningococci has been done in the English speaking countries, and down to the present time it has been possible to place nearly all strains of meningococci in one of the Gordon-Murray types. There have been a few strains

time becomes normal four hours after the injection. The intensity of coagulation depends on the amount of venom injected. The poison of the Russellii snake can be used as an emergency treatment in cases of grave hemorrhages or hemoptysis and may be repeated every four hours until the hemorrhage is controlled. There is no danger for the patient provided the dose does not exceed 0.05 mg. In simple forms of repeated hemoptysis or in cases of persistence of a bloody sputum the poison, in association with other coagulating substances, gives satisfactory results. In the authors' cases the patients were suffering from tuberculous hemoptysis or from purpura haemorrhagica. The treatment consisted in a daily intradermic injection of 0.05 mg. of the poison dissolved in 1 cc. of a 1 per thousand tricesol solution made in sodium chloride solution, followed four hours later by an injection of 10 cc. of any of the following substances: tenth normal calcium chloride, calcium gluconate or coagulen. The authors do not give the route they use for injecting the coagulating substances. For verification of results, further work on the subject is necessary.

#### Sarcoma of Knee Following Roentgen Irradiation.—

According to Becker, there were fifteen instances of sarcoma developing in a tuberculous knee treated by roentgen irradiation. All the patients received intensive irradiation over a long period. The diagnosis of joint tuberculosis was made in most cases on the basis of clinical study. There was a histologic diagnosis in two, and in two cases there was probably no tuberculosis. Sarcoma developed from five to seven years after irradiation. On histologic examination it proved to be, as a rule, a polymorphous cell tumor of pronounced malignity. The author reports the result of an uncontrolled irradiation in a personal case ending in severe injury to all the tissues of the joint. The author believes that the tuberculous process in all probability plays a subordinate part in the development of the sarcoma. The important factor is the roentgen irradiation. The epiphyses appear to be sensitive to roentgen exposure. He therefore suggests that great care be exercised in application of roentgen therapy for joint tuberculosis, particularly in the young.

#### Corneal Lesions Following Removal of Gasserian

Ganglion.—Drutter reports that, of sixty-nine patients treated by alcohol injection of the gasserian ganglion for the cure of trigeminal neuritis, seventeen (24.6 per cent) developed keratitis. In nine (52.9 per cent) the lesion remained permanent. Eighteen patients were subjected to twenty-seven operations for the removal of the gasserian ganglion. The cornea remained normal in all cases. The author concludes that neuroparalytic keratitis develops only as a result of anesthesia of the cornea. The cause of keratitis remains unexplained in spite of many studies. Primary trigeminal neuralgia seldom involves the first branch of the nerve. Pains proceeding in this area are considered secondary by many authors. The incidence of corneal anesthesia and consequent disease of the cornea cannot be diminished through the use of the alcohol injection method of the gasserian ganglion developed in Germany. The subtotal posterior ganglion section of the root of the trigeminus, according to the method of Frazier-Spiller, does not lead to the loss of sensitiveness of the cornea and to neuroparalytic keratitis. The persistence of high mortality in Germany following the operative intervention is due to the lack of experience. The treatment with alcohol injection makes the operative intervention even more difficult. The operative subtotal section has a smaller percentage of recurrences than the alcohol injection method. According to American authors, the subtotal posterior ganglion resection is the method of choice in the treatment of trigeminal neuralgia. The author suggests that the injection

method should be reserved for patients whose general condition will not justify a major procedure. Younger patients should be treated as far as possible by operative intervention so as to avoid the possibility of keratitis.

**Diagnosis of Carcinoma from Blood Serum.**—Bernhard and Köhler state that there is in carcinoma an increase of atoxyl-resistant lipase in the blood serum. The blood lipase content diminishes after operative removal of carcinoma and returns to normal after some time. There is a diminution of the atoxyl-resistant as well as of the general lipase content in all generalized lesions. The authors found an increase of the atoxyl-resistant lipase in 219 out of 313 instances of cancer. In sixty-two there was a diminution and in thirty-two a normal amount. Lipase determination is of considerable diagnostic value in carcinoma of the skin, the breast and the rectum. Its value is rather limited in carcinoma of the biliary passages and the pancreas. The atoxyl-resistant lipase is, as a rule, increased in carcinoma of the prostate, the bladder, the esophagus and the bronchi. This observation, however, is present in about 10 per cent of persons free from carcinoma. The atoxyl-resistant lipase undergoes the same alterations as in carcinoma in conditions that frequently lead to malignant degeneration, such as chronic cystic mastitis, bleeding breast, gastric ulcer, gastritis, strawberry gallbladder, goiter and chronic infections. The basis for the Fuchs reaction for the diagnosis of carcinoma lies in the observation that the serum of a normal person will not break down normal fibrin. Fibrin derived from the blood of a carcinoma patient will not be acted on by the serum of a carcinoma patient but will be broken down by normal serum. Likewise the serum of a normal person will not affect the fibrin derived from normal blood, whereas it will affect fibrin derived from the blood of a carcinoma patient. The development of a malignant tumor leads to alterations in the blood, which enable the serum of the carcinoma patient to break down normal fibrin. In the authors' experience there were 92.6 per cent of correct diagnoses in a group of 129 definitely established clinical cases of carcinoma. In a group of 164 patients not exhibiting signs of carcinoma, the percentage of negative tests was 89.2. In a group of twenty-seven patients suspected of a malignant condition, the reaction was positive in twenty-three. The accuracy of the Fuchs reaction appears to be the same for various localizations of cancer. The authors consider this reaction reliable. The application of the two methods mitigated the inaccuracies of each. The accuracy of the diagnosis of carcinoma is made more certain when both methods give a positive result. The authors have frequently found carcinoma in the forebears of healthy persons in whom both methods proved positive and in whom carcinoma and blastophil diseases were ruled out. However, the simultaneous use of the two methods does not establish the diagnosis of carcinoma with absolute certainty.

**Diagnosis of Influenza.**—Von Hoesslin points out that it is often difficult to differentiate between influenza and disorders due to colds. During an influenza epidemic there is a tendency to designate all rather severe catarrhs of the upper respiratory tract as of an influenzal nature, whereas at times when this is not the case they are designated as respiratory catarrh. However, it is incorrect to identify the two. The reason that they are so frequently identified is the great or complete conformity in the symptomatology, at least during the first days and often throughout the entire course. Psychologic factors likewise play a part, when the term influenza is applied to respiratory disorders that are caused by colds. On the part of the physician, for instance, it may be done in order to impress the patient with the necessity of following instructions and also to avoid reproach in the event of the development of complications. The author discusses the devel-

occurrence, whereas types III and IV (17 per cent each) were much less frequent.

For the next ten years there was relatively little meningitis, and there are practically no studies on the distribution of serologic types reported during that period.

In 1928 meningitis began to reappear. A wave, believed by many to have had its origin in China, moved eastward, by way of the Philippine Islands, to the California coast and spread eastward over the United States. By 1931 outbreaks began to occur in the British Isles and on the European continent. Whether these were a continuation of the wave which had moved eastward over the Atlantic, or whether the spread had been westward more slowly from the Orient is not entirely certain.

There have been a number of reports on typing of the strains involved since that time and the shift has been steadily, though rather irregularly, in one direction; namely, the overwhelming predominance of the I-III (A) group. Types I and III have seemed to cross much more than they did in the 1915-1918 period, overlapping each other so intimately that separation, even by absorption, is difficult and in some cases impos-

from Russia<sup>26</sup> in 1929 are reports that all groups are present, while Turkey declares a predominance of type B.<sup>27</sup>

Of 165 strains received by the National Institute of Health since Jan. 1, 1936, only fourteen were of type II; thirteen of these came from a single outbreak in Charleston, S. C. In this outbreak there were a few of the I-III group, but type II was the rule.

This occurrence of more than one type in a single outbreak has been noted ever since the earliest serologic studies were made. In general it may be said that a small, sharp, well localized outbreak is apt to be due to strains of one type, which may behave very much alike in all serologic relationships. The more widespread the outbreak and the longer it lasts, the more tendency is found for various types to be involved. There does not seem to be any definite sequence of type as was suggested by Gordon,<sup>28</sup> but all types and many intergradations may occur. The most extreme example of this multiplicity of type that has come to my attention is the epidemic in Chicago in 1928. The wave of meningitis that began on the west coast of the United States had seemed to be due entirely to

\* Control (standard type strains).

sible. On the other hand, types II and IV have seemed to have become entirely distinct, with no crossing. Also a new member of the genus has appeared (*Neisseria flavescens*); thus the type distribution in the United States during 1928-1930 (table 4).<sup>21</sup> Type II by this time had last place.

In our studies made during 1934-1936, more than 95 per cent strains have been of the I-III group. Type II strains have been increasingly few, and no type IV strain (or *N. flavescens*) has been encountered since 1928.

Information about the geographic distribution of types is very incomplete, consisting necessarily of isolated reports from here and there. But one gains an impression that the trend toward the preponderance of the I-III (A) group has been world wide and not local. Reports from India<sup>22</sup> and South Africa<sup>23</sup> indicate this, as well as the British reports of several outbreaks of type I in 1931.<sup>24</sup> From Germany<sup>25</sup> in 1928-1929 and

the I-III group. When it reached Salt Lake City the strains that were isolated were crossing very markedly with type II, so much so that absorption of agglutinins was necessary to type them. In Chicago the strains forsook all precedent. All types were present, but IV was predominant, with second place taken by a coccus which was not really a meningococcus. It was a member of the same genus, morphologically indistinguishable, but neither culturally nor serologically a meningococcus. All strains of this organism formed a clear cut serologic group; they fermented no sugars and produced a golden yellow pigment. I have called this micro-organism *Neisseria flavescens*<sup>29</sup> (literally "becoming a golden yellow"). We encountered no like strain outside of Chicago and have never found it since, though it was found abundantly there at that time by three independent investigators. So far as I know this is the only record of a member of the genus *Neisseria*, other than the meningococcus, being involved in an epidemic of meningitis, and it seems of considerable epidemiologic importance.

Only one culture of a type IV meningococcus was found outside of Chicago, and this came from a man

## EFFECTS OF VERY EARLY SERUM TREATMENT IN PNEUMOCOCCUS TYPE I PNEUMONIA

RUSSELL L. CECIL, M.D.  
NEW YORK

It is a fundamental principle in all serum therapy that to obtain the best results the serum must be given early in the disease. This statement holds true regardless of whether one is using antitoxic or antibacterial serum. During the past decade there have appeared in American and British medical literature a goodly number of reports on the successful use of refined and concentrated antipneumococcus serum in the treatment of pneumococcic pneumonia. The majority of these reports have dealt with pneumococcus type I infections. More recently, however, a number of articles have appeared, reporting favorable results with serum in the treatment of other types of pneumococcic pneumonia. Promising figures have been submitted for the serum treatment of types II, V, VII, VIII and XIV. The most significant feature of these reports on serotherapy is that they are all, without exception, favorable. I cannot recall a single skeptical article since the introduction of Felton's concentrated serum. Many of the authors, after reporting their results in a series of cases studied, have given mortality figures for cases treated during the first three or four days of the disease. In every case the mortality rates for cases treated early are distinctly lower than the death rate for the whole series, and much lower than the death rate for cases treated late in the disease.

It occurred to me that an analysis of a series of cases of pneumococcus type I pneumonia in which serum was administered unusually early in the course of the disease, that is, during the first twenty-four hours of the infection, might throw some interesting light on the ultimate possibilities of serum therapy in this type of pneumonia. Not so very long ago I made the statement that it was doubtful whether the death rate for type I pneumonia could be reduced below 10 per cent by means of serum therapy. This statement was based on the observation that so many patients with pneumonia suffer from a previously depleted condition, due to influenza, childbirth, a surgical operation or some chronic systemic disease, such as tuberculosis, diabetes or cancer. By way of contrast, I had in mind diseases like diphtheria and scarlet fever, which occur almost exclusively in healthy children and the physician has only one medical problem, namely the acute infec-

tion, to combat. However, figures which I shall presently show indicate that I may have been too pessimistic in my prognostications.

I will now consider briefly the various phenomena which manifest themselves when concentrated antipneumococcus type I serum is administered quite early in type I pneumonia. A very frequent and happy manifestation of early serum treatment of type I pneumonia is a complete and dramatic abortion of the infection. The patient, from having been acutely ill, with a high temperature, pleuritic pain, marked restlessness, and paroxysms of coughing, suddenly finds himself well (chart 1). The temperature is normal or subnormal. The pulse and respiration return to their usual rates. Pleuritic pain disappears and the cough is ameliorated. From being a serious, exhausting infection of seven or eight days' duration, the disease is reduced almost to the status of an influenzal attack. I believe that these instances of dramatic termination are explained by the fact that in the early phases of the disease, before frank consolidation has developed to its maximum intensity, the specific antibodies of the serum are capable of so affecting the pneumococci in the pulmonary lesion as to bring about a rapid cessation of the infection. Once consolidation is complete, the circulation through the affected lobe is seriously impaired. After this stage has been reached, usually by the third or fourth day of the disease, the chief effect of the injected immune bodies is to confine the pneumococci to the pulmonary lesion and to prevent extension of the pathologic process. Under the latter circumstances the actual termination of the disease is brought about by the process of natural recovery. This point of view is well supported in some recent studies by Robertson and his co-workers.<sup>1</sup>

The striking subjective improvement in these patients results, of course, from the sudden elimination of toxemia. The toxemia of pneumonia is a problem that is not thoroughly understood. Coca<sup>2</sup> has demonstrated in filtrates of pneumococcus type I cultures a toxin which, when injected into young children, causes a rise of temperature, which may reach 105 F. in the more susceptible subjects. On the other hand, patients convalescing from pneumococcic pneumonia were found immune to the type I toxin. According to Coca, the toxin appears to be type specific but is not the type-specific polysaccharide. If Coca's studies are corroborated, it may be assumed that antipneumococcus serum, in addition to neutralizing the type-specific polysaccharide, neutralizes the type-specific toxin as

2. Coca, A. F.: A Study of the Pneumococcus Toxins, *J. Immunol.* 30: 1 (Jan.) 1936.

The carbohydrates of the meningococci have been studied by Zozaya and Wood,<sup>42</sup> by Miller and Boor<sup>43</sup> and by Scherp and Rake.<sup>44</sup> Zozaya and Wood found one polysaccharide common not only to meningococci but to all members of the genus *Neisseria* as well. Scherp and Rake have found, in addition, specific carbohydrates for types I, II and III. Types I and III were found to have the same carbohydrate, and analysis has shown it to be a sodium salt of a polysaccharide acid. The specific carbohydrate of type II has not yet been thoroughly studied, and that of type IV has not yet been investigated.

There is apparently no relationship between electrical charge and type. Studies made by Gibbard<sup>45</sup> and also by me<sup>46</sup> indicate that recently isolated strains of all types have a higher charge than older strains which have had a period of laboratory maintenance, but this was not correlated with type by either of us.

What rôle does serologic type play in serum therapy of meningococcic meningitis? The use of specific monovalent serum has been difficult because the outcome of any given case is so often determined before the type of the infecting meningococcus is known. Thus the general practice is to administer polyvalent serum in all cases. In Great Britain there has been a tendency to administer specific type I-III or II serum after the type is known. There is experimental evidence both for and against such specific therapy. Gordon<sup>47</sup> found that his rabbits had immunity only for the types with which they had been immunized, while Evans<sup>48</sup> found in her animals just as much immunity for heterologous strains.

Typing by a precipitation test, recently described by Rake,<sup>49</sup> can often be done at the bedside and may result in increased use of monovalent serum and the accumulation of more information about its relative usefulness.

This bedside typing can be applied to only a limited number of cases, since there must be abundant specific soluble substance in the spinal fluid and the patient must not have had any serum therapy.

The antitoxin of Ferry has seemed to be more useful in cases due to group I-III strains.

#### COMMENT AND CONCLUSION

Classifications of meningococci, worked out in the years 1909-1918, represented true serologic relationships which can be plainly recognized today.

Certain changes in these relationships have taken place; types I and III have become so closely inter-related that separation into two types no longer seems to be of definite value in practical everyday work. This I-III or A group has become markedly predominant in nearly all parts of the world that have been heard from.

On the other hand, types II and IV have in the United States at least become entirely distinct from

each other so that they do represent two separate groups. There seem to be three types of meningococci: I-III, II and IV. The designation B cannot be well applied to a combination of two such distinct groups as II and IV.

Studies made long ago and at the present time seem to indicate a greater number of type II strains in carriers. This large number of carriers of strain II in proportion to the very small number of type II cases brings up this question: Is II less pathogenic than I-III? This idea finds some support in the following fact: Although 70 per cent of all strains isolated from blood were type II, nearly all the cases of meningococcic endocarditis in which the type has been determined have been due to the I-III group. There is some evidence that type II is especially apt to be responsible for septicemic and generalized forms of meningococcic infection, which may be relatively mild or chronic.

Both the endotoxins of Gordon and the soluble toxins reported by Ferry are produced to a greater extent by the I-III group. Thus one finds at present a predominance of that group of meningococci which seems to be both more invasive and more toxic.

## THE SURGICAL TREATMENT OF MENINGITIS OF OTITIC AND NASAL ORIGIN

GEORGE E. SHAMBAUGH JR., M.D.

CHICAGO

In a recent article Ferris Smith<sup>1</sup> called attention to the well organized exudate at the base of the brain as compared to the more recently appearing exudate over the cerebral hemispheres in patients dying of meningitis of otitic or nasal sinus origin. This suggests that there is a stage of localized basilar meningitis lasting from hours to days before the onset of generalized meningitis. The author advocated early incision and drainage of the dura beneath the pontile cistern by way of a burr opening in the sphenoid bone, made through the posterior wall of the sphenoid sinus or through the roof of the nasopharynx. Three cases of early meningitis treated by this method were reported, with one recovery. In two patients the meningitis was from the sphenoid sinus, the lumbar spinal fluid showing 1,800 cells per cubic millimeter in one, 190 cells in the other. Organisms were not present on smear or culture of the spinal fluid in either case. The third patient had an otitic meningitis and showed 1,920 cells with organisms in the spinal fluid.

Because the radical procedure advocated by the author runs counter to the accepted treatment<sup>2</sup> of early otitic or nasal sinus meningitis, it seems pertinent to review a series of five consecutive cases of meningitis successfully treated according to certain principles that are coming to be generally accepted. These principles are briefly as follows:

Every patient with suppurative disease of the accessory nasal sinuses or of the middle ear should have an immediate lumbar puncture at the first evidence of beginning meningitis: a slight stiffness of the neck with headache, fever, irritability, drowsiness or vomiting.

† Cases collected from various authors.

monia they induce a cutaneous reaction in those infected with the homologous type of pneumococcus. The character of this reaction is of the wheal or erythema type. The patient's capacity to react to the homologous polysaccharide is intimately associated with recovery and with the presence of type-specific antibodies in the circulating blood.

Francis<sup>7</sup> has recently shown that the polysaccharide skin test can be made use of as a valuable guide in serum therapy. In the opinion of Francis a positive skin test inevitably denotes that recovery has begun. When negative, it indicates the need of further serum therapy. Francis believes that the mechanism of the positive skin test is closely related to that operative in recovery from pneumonia and is apparently a resultant of antibody and tissue activity. In the illustrative charts presented by Francis, the appearance of a positive skin reaction was usually but not always coincidental with the appearance of specific agglutinins in the circulating blood. Both of these responses were closely associated with the critical fall in temperature and other evidences of recovery. Abernethy<sup>8</sup> has confirmed the value of the polysaccharide skin test in controlling serum therapy. He found that approximately 200,000 units was the amount required in treating the average uncomplicated case of type I pneumonia.

In most case reports on the effect of treatment of type I pneumonia with antipneumococcus serum, the death rate for patients treated during the first three or four days of the disease has averaged 10 per cent; in other words, a reduction to about one-third the standard death rate (33 per cent). The opportunity to give serum to a patient with type I pneumonia during the first twenty-four hours of the disease does not often present itself. This is most unfortunate, for, as I shall presently show, the results obtained by such very early treatment are truly spectacular. With the rapid typing methods now in vogue, there is no reason why more pneumonia patients should not receive early therapy. In order to determine more accurately the effects of very early serum treatment, I have collected a series of 160 cases of type I pneumonia in which concentrated type I serum was administered during the first twenty-four hours of the disease. Thirty-seven of these cases are from my own records. The remainder have been collected from the records of Bullowa,<sup>5</sup> Heffron<sup>9</sup> and Rogers.<sup>10</sup> In table 1, I have summarized the data obtained from my own thirty-seven cases. The average age in this series was 36; the average total dose of serum, 181,000 units; the average duration of fever for patients who recovered was 4.7 days. The latter figure is quite significant when it is recalled that the average duration for type I pneumonias in cases in which no serum is administered is seven days. In other words, the average duration of the disease was cut almost in half. In many cases the temperature dropped to normal in less than forty-eight hours after onset.

In 78.4 per cent of these patients who received serum early only one lobe was infected. In 21.6 per cent there was involvement of two lobes. There was no way of knowing whether both lobes were already involved at the time serum was given or whether a spread took place after the injection of serum. This point could probably be settled by careful x-ray study of a series of cases.

The most interesting feature of this series of thirty-seven cases was the practical absence of complications. When one recalls that empyema occurs in more than 6 per cent of type I pneumonias, the complete absence of this complication in the present series is quite significant. Indeed, there were no complications of any kind in these thirty-seven cases, except one instance of acute parotitis.

There were only two deaths (5.4 per cent), a remarkably low figure for such a serious disease. One of these deaths occurred in the group of ten cases collected from my private practice. The patient was a

Chart 3.—Septic type I pneumonia treated during first twenty-four hours of disease with concentrated antipneumococcus serum. Upper solid line, temperature; lower solid line, bacteremia; broken line, protective bodies in patient's serum.

9. Heffron, Roderick: Personal communication to the author.

10. Rogers, E. E.: Personal communication to the author.

May 14 the left sigmoid sinus was explored and found to contain a partly broken down thrombus. The jugular vein was ligated and the thrombus removed until bleeding was obtained at about half way from the knee to the torcular herophili. Convalescence from that point on was rapid and uneventful. The facial paralysis began to recede by May 26, the date of discharge from the hospital, and had completely disappeared two months later.

This patient had a localized meningitis from a focus in the labyrinth with 2,900 cells in the spinal fluid but no organisms. Drainage of the focus sufficed to cure the meningitis without the necessity of incising and draining the dura.

CASE 3.—J. C. D., a child, aged 4 years, admitted to the Presbyterian Hospital June 5, 1932, complained of bilateral discharging and painful ears for three weeks with an irregular fever as high as 103 F. and beginning stiffness of the neck noted the day before. On examination the child was irritable and uncooperative with definite, slight rigidity of the neck, bilateral aural discharge and only slight mastoid tenderness. Lumbar puncture showed 68 lymphocytes per cubic millimeter in the spinal fluid with a positive Nonne test for globulin.

Bilateral mastoidectomy the same day showed a coalescent mastoiditis. The dura was extensively exposed over the tegmen on both sides and appeared normal except for slight hyperemia. Culture showed *Streptococcus haemolyticus*. Convalescence was uneventful, the patient being discharged home on the tenth day after operation.

This was a case of very early localized meningitis from an otitis media and mastoiditis. Removing the focus and exposing the dura widely (thus breaking off all infected venules running from the mastoid to the dura) resulted in recovery.

CASE 4.—D. S., a boy, aged 7 years, was seen July 8, 1936, with a history of an earache in the right ear six weeks before with spontaneous rupture of the drum membrane the next day. Discharge from this ear was profuse and after the first week was accompanied by considerable pain behind the right eye and an irregular fever as high as 104 F. There was no mastoid tenderness, but because of the fever a roentgenogram of the mastoid had been made two weeks after the onset, showing

there was a slight spontaneous nystagmus toward the right ear, the neck was slightly rigid and the Kernig sign was positive. The white blood cell count was 30,000. Lumbar puncture showed the spinal fluid to be under normal pressure but cloudy with 4,000 cells per cubic millimeter, practically all polymorphonuclears. Gram-positive cocci, in pairs and in chains, were found on smear (but subsequently there was no growth on culture). There was no reduction of copper sulfate.

The diagnosis was suppuration of the right petrous apex with perforation of the cortex and beginning generalized meningitis. Immediate drainage of the petrous apex was advised and carried out. The mastoid wound was reopened and a fistula of softened bone was found posterior and inferior to the posterior semicircular canal leading medially and anteriorly. A probe could be passed inward and forward to the depth of 1½ inches (3.7 cm.) beyond the horizontal semicircular canal. The fistula was enlarged, exposing the dura of the posterior fossa, and a small rubber drain was inserted.

At the completion of the operation the child's temperature was 108 F. (rectal) and his general condition very poor. After iced compresses and subcutaneous dextrose the temperature fell to 103.4 F. but the child presented the picture of shock with cyanosis, shallow, irregular respiration and a very rapid, barely perceptible pulse, and the blood pressure could scarcely be obtained from the arm at 40 systolic. Intravenous dextrose 10 per cent and caffeine subcutaneously resulted in a steady improvement; the blood pressure at the arm rose from 40 systolic at 2 a. m. to 105 systolic, 80 diastolic at 5 a. m., the temperature rising to 105 F. The neck was quite rigid but during the day the temperature began to fall, the rigidity of the neck began to disappear, and with the help of transfusions convalescence has been uneventful. The discharge from the middle ear immediately ceased but continued from the fistula, gradually diminishing in amount, for two months.

A patient with apparently hopeless, generalized meningitis recovered following simple drainage of the focus in the petrous apex. Although organisms were found in the smear, the spinal fluid culture proved negative and incision of the dura was not required.

CASE 5.—J. C., a Negro laborer, aged 63, came to the Central Free Dispensary April 22, 1933, because of a right otorrhea of two weeks' duration. Three and a half weeks after the

Chart 1 (case 4).—Temperature in early meningitis with 4,000 cells in the spinal fluid, organisms on smear but not on culture, with recovery following drainage of the focus in the petrous apex.

only clouding of the cells; four weeks after the onset, a second roentgen examination showed cell destruction.

Because of the continued pain behind the eye, the fever and the changes found on roentgen examination, a simple mastoidectomy had been performed July 3 by Dr. Minor E. White of Kankakee, Ill. Marked cell destruction was found over the lateral sinus but the sinus wall itself when exposed appeared normal. Culture showed *Streptococcus haemolyticus*.

Following the mastoidectomy the pain behind the eye, the fever (chart 1) and the profuse discharge from the middle ear persisted, but there were no other symptoms until July 8. On the morning of July 8 the child complained of double vision, which lasted for only half an hour. The temperature rose to 104.4 F. following a slight chill, and an intermittent spontaneous nystagmus was noticed.

When I first saw the child, in consultation in the afternoon, his temperature was 105.8 F., he was very listless and pale,

onset pain and tenderness over the mastoid developed. The patient was referred to the Cook County Hospital, where a simple mastoidectomy May 2 revealed the cells filled with granulations and pus, with considerable softening of the cell partitions. Convalescence was uneventful except for persistent postaural discharge until May 25, when severe vertigo with nausea and vomiting was experienced. The gait was unsteady; there was a spontaneous nystagmus, mostly horizontal, toward the unoperated ear. Hearing, caloric and rotation tests all showed a dead labyrinth on the operated side. The diagnosis of acute suppurative labyrinthitis was made.

The symptoms gradually subsided until June 6, when the patient complained of an occipital headache and felt ill. There was definite beginning rigidity of the neck and the temperature was 102.6 F. He was admitted at once to the Presbyterian Hospital, where lumbar puncture revealed 1,400 cells and 63 per cent polymorphonuclears but no organisms on smear or culture.

that have not belonged in this classification but have formed other groups; these have been uncommon. I shall speak more of them later.

These types among the meningococci are not as clear cut and sharply defined as are those of some other bacteria; namely, the pneumococci. Nearly all strains show a degree of overlapping, and in some this is so marked as to make typing, even by absorption of agglutinins, well nigh impossible. This means that the representative strains of each type must be chosen with great care, especially if they are to be used for making typing serums. The antigenic patterns of different strains of meningococci may be said to be made up of four components in different proportions, and the predominant component determines the type of any individual strain. This has been illustrated by diagrams representing several strains of the I-III group.<sup>9</sup> Table 2 shows that strains typed as I when certain type I and type III strains were used as standards can be typed as III when other strains of these types were used as standards. As Fildes<sup>10</sup> has aptly expressed it: "The classification of meningococci is real and is not dependent upon arbitrary selection of standards. But selecting standards for determining subgroups is arbitrary and may lead to much confusion if one and the same standard is not maintained."

Thus it is seen that quite different results may be obtained in typing the same cultures in different laboratories. This has been emphasized by Griffith<sup>11</sup> as well as by Fildes. With certain serums prepared from members of each of the four types, a division into four distinct groups could be effected by means of absorption of agglutinins. With serums prepared from other members of each type, differentiation into similar groups could not be made.

Not only do different strains of the same type vary in antigenic pattern but a given strain may change surprisingly in this respect. I shall give one striking example of this change, which is found on comparing Dr. Gordon's original standard type I strain, "Littledale," which has had more than twenty years of laboratory maintenance, with a dried suspension of the same strain which Dr. Gordon, with remarkable foresight, prepared in 1915 when it was originally isolated and studied. It now falls definitely in type III. There seems to be no possible doubt about this change, as identical results with it have been obtained not only by myself but by Dr. Scott<sup>12</sup> of the British Ministry of Health and by Dr. Maegraith<sup>13</sup> of Oxford University. Dr. Gordon kindly supplied the dried material, and the living transplants of the Littledale strain were obtained from several different sources. Examples such as this can be multiplied.

It has not been possible to study the standard type strains of other countries and to compare them with the original dried strains. Twenty years ago they were in close agreement, whether called types I-III and II-IV or A and B; but twenty years of laboratory maintenance in different countries and under different environmental conditions has probably led to a wide divergence in the antigenic pattern of the strains used as standards.

Wulff<sup>14</sup> has described an epidemic in Denmark in which only one strain seemed to correspond with any English type, but 95 per cent fell into a group which corresponded to the French type A. Originally the French type A and the English type I-III seemed to be identical.

All strains tend to spread and are much more easily typed when first isolated than later. Several workers have reported that they consider the strains of group II to become irregular in classification more quickly than others.<sup>15</sup> This means that serologic studies done in various places cannot be compared on account of a lack of a uniform basis. This is a handicap in epidemiologic studies and in the manufacture and standardization of therapeutic serums. It is important that there be a uniformity of standard strains among different nations. It makes no difference whether the serologic groups are designated as A and B or as I-III and II-IV provided the type strains actually represent their classification and the relation of the classifications to each other is understood. Standard strains should be kept true to type in a central laboratory somewhere, and dried cultures of them, as well as living transplants, should be

TABLE 1.—The Relationship Between Various Classifications of Meningococci\*

available from this place to all who want them. It should always be kept in mind that the living culture is changing and that the dried culture is presumably fixed.

At the time when Gordon first reported his classification into four groups, type I was predominant. Gradually type II became more abundant. During 1915-1917 the distribution seemed to be about as shown in table 3.<sup>16</sup>

Dopter<sup>17</sup> made a similar report that, at the beginning of the war his meningococcus proper (A, I-III) was most common but that by 1916 the parameningococcus (B, II-IV) had become as much as 45 per cent of the cases. In 1917-1918 Netter<sup>18</sup> found type B (II-IV) twice as common in France as type A (I-III), and Glover<sup>19</sup> in England reported an outbreak due entirely to type II in 1918.

In the United States Hitchens and Robinson<sup>20</sup> found types I and II (33 per cent each) to be about equal in

## COMPARATIVE RESULTS WITH DIETETIC, PARENTERAL AND SURGICAL TREATMENT IN PEPTIC ULCER

### PRELIMINARY REPORT ON THE PROTECTIVE VALUE OF HISTIDINE (LAROSTIDIN) IN EXPERIMENTAL ULCERS IN DOGS

DAVID J. SANDWEISS, M.D.  
DETROIT

This paper has a twofold purpose: first, to present clinical data evaluating my results with parenteral therapy in peptic ulcers; second, to present at the end a preliminary report (in association with H. C. Saltzstein and W. S. Glazer) on the protective value of histidine against experimental ulcers in Mann-Williamson dogs.

Many forms of parenteral treatment have been reported as beneficial since Holler<sup>1</sup> of Vienna announced in 1922 his experience with "vaccineurin." The more important of these agents have been enumerated in my previous report.<sup>2</sup> Newer ones are constantly coming to the fore. Judging from the increasing number of reports and the favorable results claimed, parenteral therapy is gaining a wide following and appears to offer great encouragement.

### CLINICAL INVESTIGATIONS

In an attempt to determine the place of parenteral therapy in the management of peptic ulcer, several series of patients were studied:

1. A series of patients treated by the standard ambulatory diet-alkali regimen was reviewed to learn in what percentage of ulcer attacks and in what type of patients this method of treatment fails to produce symptom-free intervals; also to determine what types of patients manifest a high proportion of relapses within six months and within one year.

2. Several series of patients with chronic ulcers were treated by various parenteral methods. These were divided into two groups: (a) an unselected group and (b) a group of patients who failed to become symptom free on ambulatory diet-alkali management. In neither group was dietary treatment changed when parenteral therapy was begun. Histidine, vaccine and emetine

were the agents used. Two series of patients treated by histidine and vaccine therapy and reported in previous communications<sup>3</sup> are included in this study. Injections of distilled water were administered to a control group. Another control series of chronic ulcer patients was treated by the ambulatory standard diet-alkali regimen. Immediate and remote results were then compared.

Throughout this paper emphasis is laid on the number of ulcer attacks treated rather than on the number of patients under observation. The reason for the emphasis is to me a purely rational one, since it permits a clearer portrayal of the life-history of the ulcer and enables a more accurate evaluation of the success or failure of therapy over a period of time. For example, a patient may fail to respond at the present time to diet-alkali management, although he has responded well on ten previous occasions and may again respond favorably in the future. It would not be accurate to report this as a single case of failure of the diet-alkali regimen, since ten of the eleven attacks were successfully treated by this method.

The clinical studies reported in the present paper are based on observations of 291 patients with peptic ulcer who were treated during 1,019 attacks (table 1). This group is a heterogeneous one representing patients from 14 to 74 years of age, of both sexes and encountered in private as well as in clinic practice. Patients from private practice present on the whole an average or better than average social and economic

status. Clinic patients naturally represent lower economic and social strata with consequent dietary and environmental handicaps. All races, Negroes, Americans and foreign born, are represented.

All patients were arbitrarily divided into two groups: (a) acute: ulcer symptoms of less than five years' duration and (b) chronic: ulcer symptoms lasting more than five years.

All patients presented the typical ulcer syndrome. All clinic patients had positive x-ray signs of ulcer. Three per cent (all in the private patient group) had

in Kansas City who had just visited Chicago. No type IV strains has been encountered since that time.

From that time on, as the wave moved eastward, the strains involved were found to be chiefly of type I-III with a few of type II.

The only two outbreaks that have been almost exclusively due to type II have, strangely enough, both occurred in the Carolinas—one in 1928 and one in 1936, eight years apart.

Does more than one type occur in any given case? Such instances have been reported; cases in which more than one type was present throughout the disease,<sup>30</sup> others in which the type seemed to change during convalescence,<sup>31</sup> and in carriers in which one type replaced another. Such reports are very few, but their rarity may be due to the fact that repeated typing of cultures obtained from a given patient is seldom done.

During 1915-1918 many surveys of meningococcus carriers were done, both in military camps and among civilian populations. From these studies a definite impression arose that type II was predominant among carrier strains and that type I led among active cases.<sup>32</sup>

Interesting are the results obtained by Tulloch,<sup>33</sup> who found 410 carriers among 10,000 men. The type distribution is given in table 5.

Within recent years relatively few surveys of carriers have been made, but there is some evidence to show that such a distribution still occurs. Rake<sup>34</sup> found type II in twenty-one of twenty-six carriers in a careful survey in 1934. During the spring of 1936 Hitchens<sup>35</sup> made surveys of carriers in a camp of young men among whom several cases of meningitis had occurred. The cases were due to type I-III; but of thirty-nine carrier strains only seven were of group I-III, whereas twenty-five, or nearly 65 per cent, were of group II.

Is any one type more pathogenic than another? It is particularly difficult to find an answer to this question, for in any given outbreak the predominant type is conspicuously responsible for a greater number of deaths. In 1917 Gordon<sup>28</sup> believed that type I infections were the most severe. This view was definitely shared by Andrewes.<sup>36</sup> In the outbreaks of very recent years type II cases have been too few to permit generalization. Is this scarcity of type II cases, contrasted with the abundance of type II among carriers, to be interpreted as evidence of low pathogenicity? Certainly most of the fulminating cases have been due to group I-III, since so few of II were present. However, one of the most explosive outbreaks of fulminating and hemorrhagic cases was due exclusively to type II; namely, a small outbreak in North Carolina in 1928.

There does seem to be considerable evidence that type II is especially apt to be responsible for septicemic and generalized forms of meningococcic infection. Netter<sup>38</sup> noted this in France in 1917. Linden<sup>37</sup> called

attention to it in Denmark in 1930. In my own studies I noted that, although I found only thirteen type II strains during 1928-1930, only four of the thirteen came from spinal fluid; the others were from blood stream infections, several of which were mild and chronic. These type II strains comprised 70 per cent of the strains recovered from blood during this period.

A few cases of meningococcic endocarditis have been reported. In those instances in which the type has been determined the strains involved have been usually of the I-III group. Does this circumstance offer additional evidence that type II is less pathogenic than I-III?

Do different types of meningococci vary in toxicity? Apparently the answer to this question is definitely Yes. Gordon<sup>28</sup> noted as early as 1917 that type I meningococci produce more powerful endotoxins than do other types. The soluble toxins described by Ferry<sup>38</sup> are produced chiefly by certain strains of the I-III group, notably by some belonging to type III.

20%	37%	0	37%

Are there cultural, biochemical or other physiologic differences to be noted among the various types of meningococci? Colonies are generally indistinguishable on the usual mediums, and certainly there are no differences in morphology or arrangement of cells. Differences in fermentation activity have been noted by some workers. Both Scott<sup>31</sup> and Griffith<sup>39</sup> considered that serologic grouping was definitely related to the degree of fermentative activity on dextrose and maltose and that individual strains of meningococci rarely fermented these sugars to an equal degree; maltose was fermented more strongly by the I-III group and dextrose by the II-IV group.

Petrie<sup>40</sup> showed that colonies of meningococci would produce halos of precipitate on solid mediums containing the homologous serum. Kirkbride and Cohen<sup>41</sup> have found that it is the I-III group which does this and that the type II strains which they studied did not have this property. Type IV strains have not been studied in this way.

management, 65 per cent became symptom free on a subsequent diet-alkali regimen (table 8). This demonstrates the value of instituting parenteral therapy in patients who do not respond to standard management, and also the value of alternating treatment in refractory cases before resorting to surgery (unless emergency indications arise).

Fig. 1.—Mann-Williamson operation. The duodenum is diverted into the terminal ileum. The stomach is anastomosed to the jejunum. (Eusterman and Balfour.)

4. The percentage of relapses at the end of one year was higher in the parenterally treated cases than in the control group subjected to diet-alkali treatment (table 9).

5. The best results in medical management of refractory cases, however, are obtained with hospitalization. Eighty-four per cent of the attacks were immediately relieved by hospital bed rest and diet-alkali management (table 8). The percentage of relapses in the latter group at the end of five years is less than the percentage of relapses at the end of one year with vaccine, histidine or emetine therapy (table 9). *This is very important!*

TABLE 6.—Immediate Results: Parenteral versus Diet-Alkali Management: Chronic Cases (on Basis of Attacks)

Method of Treatment	Patients	Attacks	Per Cent Symptom Free

Ambulatory diet-alkali (chronic).....	55	55	53

6. Although surgical treatment gives the highest percentage of immediate symptom-free intervals (89 per cent, table 8) and the smallest percentage of relapses within one year (46 per cent, table 9), it nevertheless shows recrudescence in 76 per cent of patients within five years (table 9). The total of known relapses is highest in the surgical series (93 per cent, table 9). This is true not only of those operated on in different localities and other institutions and who later returned to us for treatment of relapses or for gastrojejunal ulcers (naturally those who continued to be symptom free did not report to us) but also of those operated on under our observation. Of the seventy operations

in the present series, thirty-four were performed in Detroit (by different surgeons). Of these patients, three (8.8 per cent) died postoperatively, one was moderately improved and thirty (88 per cent) became symptom free. I was able to follow up twenty-five of these thirty symptom-free patients. Twenty-two (88 per cent) are known to have developed relapses of ulcer symptoms. Only three are known to be symptom free. Considering therefore the risks of surgery, the postoperative mortality, the recurrence of ulcer after operation and the not infrequent development sub-

TABLE 7.—Immediate Results: Parenteral (Injection) Treatment: Chronic Cases (on Basis of Attacks)

sequently of gastrojejunal ulcers (which bring even greater difficulties in medical management), I do not think that surgery is the treatment of choice in peptic ulcer, unless the following indications are present: (a) Perforation. (b) Gastric ulcer suspected of malignancy. (c) High grade obstruction, not relieved by adequate medical management. (d) Repeated and frequent hemorrhages.

#### ACCOMPLISHMENT AND USEFULNESS OF PARENTERAL THERAPY

Table 10 illustrates the percentage of attacks that necessitated hospitalization and surgical intervention before and after parenteral therapy was instituted at

Fig. 2.—Dog died twelve days after operation; 20 cc. of histidine (800 mg. of histidine monohydrochloride) had been given. Inflamed with necrosis of surface.

the North End Clinic. Table 11 shows what I believe may be expected from the use of parenteral therapy in all types of ambulatory ulcer patients.

1. Fewer patients were hospitalized and fewer patients were operated on after parenteral therapy was instituted. However, in most of the parenterally treated

If the spinal fluid cell count is elevated but organisms are not found on smear, the suppurative focus in the sinus (case 1), in the labyrinth (case 2) or in the mastoid should be drained. In the case of the mastoid the dura should at the same time be widely exposed over the tegmen of the middle ear and mastoid (case 3). As long as organisms are absent from the spinal fluid the meningitis should be regarded as a localized process adjacent to the focus, and the dura should not be incised. Occasionally a few organisms may be found on smear in early meningitis, but there is no growth on culture, showing that these organisms are not viable, and drainage of the focus will still suffice to produce a cure (case 4). On the other hand, once a diffuse, generalized, suppurative meningitis has developed with organisms on smear and culture, surgical drainage of the basal cisterns by the method of Eagleton<sup>3</sup> (case 5) or perhaps by the method of Ferris Smith<sup>1</sup> may be attempted, though the latter procedure is open to the theoretical objection of exposing the spinal fluid to the mixed flora of the nasopharynx.

During the past four years eight cases of meningitis of otitic or nasal sinus origin have been observed in practice or in the house service of the Presbyterian Hospital. Two patients died of sepsis (thrombosis of the lateral sinus in one, thrombosis of the superior sagittal sinus in one) and one patient died of duodenal hemorrhage. The meningitis in these three cases was localized and was not the immediate or contributory cause of death. The remaining five cases of meningitis were treated successfully, as shown in the following reports:

#### REPORT OF CASES

CASE 1.—Mrs. R. K., aged 40, was admitted to the Presbyterian Hospital Dec. 30, 1932, because of constant, very severe, left frontal and occipital headache. Her illness began six months before with a severe sore throat, which was soon followed by a purulent postnasal discharge and severe left sided headaches. A month after the onset the left ear began to discharge and continued for two months, but for the past three months the ear had been dry. One month before admission she experienced a severe attack of vertigo and a week later a left facial paralysis and double vision developed, and these had persisted.

Examination on admission disclosed a complete peripheral left facial paralysis, paralysis of the left inferior rectus muscle and marked general emaciation and pallor. The drum membranes were intact and the nasal passages appeared normal, but in the roof of the nasopharynx above the left eustachian orifice a fistulous opening was seen exuding creamy pus and surrounded by granulations. Culture of this pus showed an abundant growth of *Staphylococcus aureus*. The spinal fluid was under normal pressure but slightly cloudy, with 486 polymorphonuclear leukocytes per cubic millimeter and no organisms on smear or culture. Because of the recent otitis media and the vertigo and facial paralysis the most likely focus for this early meningitis seemed to be the left petrous apex with a fistula into the nasopharynx.

The patient's symptoms did not improve and Jan. 9, 1933, the left petrous tip was explored by a radical mastoidectomy, following which the dura was elevated and a groove was made in the anterior surface of the petrous pyramid between the cochlea and the carotid artery, beginning above the eustachian orifice and going medially and slightly posteriorly to the depth of 1 inch (2.5 cm.). No evidence of bone disease was found.

The severe headaches continued with constant nausea and occasional vomiting and with a low grade, irregular fever reaching 102 F. Repeated examinations of the nasal cavities were negative until on one occasion pus was seen coming from the region of the ostium of the left sphenoid sinus. The diagnosis was suppurative left sphenoiditis and osteomyelitis of the sphenoid bone.

January 18 the left sphenoid sinus was opened intranasally and found to contain creamy pus. The severe headaches were immediately relieved and the other symptoms gradually improved until the patient was discharged, February 25.

Two weeks later, March 10, the patient was readmitted to the hospital because of a severe frontal and occipital headache for one week, and nausea and vomiting for two days. The neck was slightly rigid. Lumbar puncture showed 357 cells, 50 per cent polymorphonuclears and no organisms on smear or culture. A week later the symptoms were slightly improved and the spinal fluid contained 187 cells. March 30 the spinal fluid showed only 97 cells, all lymphocytes. Under general supportive treatment, including an autogenous staphylococcus vaccine made from the nasopharyngeal fistula, the symptoms gradually improved, the fistula healed, and the patient was discharged May 14.

For three years she enjoyed excellent health. In July 1936 she became ill with severe headaches, ataxia of the left arm and leg and spontaneous nystagmus. Because her immediate relatives were Christian scientists she was not seen until she became semicomatose two weeks later. The spinal fluid was under increased pressure (300 mm.) with 30 cells. There was slight rigidity of the neck, the eyegrounds showed an early papilledema and the temperature was 99 F. A provisional diagnosis of left cerebellar abscess was made. Hypertonic dextrose solution was given to reduce the intracranial pressure, but the coma deepened and a few hours later she suddenly became cyanotic and respirations stopped, the pulse continuing for some minutes. Permission for autopsy was refused.

This patient when first seen had a localized, basilar meningitis secondary to an empyema of the sphenoid sinus and an associated osteomyelitis of the sphenoid bone with a fistula into the nasopharynx. Recovery from the meningitis followed simple drainage of the sphenoid sinus. Additional drainage of the sphenoid bone by the method of Ferris Smith would probably have accelerated recovery, but incision and drainage of the dura were not necessary.

CASE 2.—E. O. Jr., aged 8 years, was admitted April 17, 1933, because of repeated vomiting and dizziness for three days with a left suppurative otitis media for three weeks, which began ten days after the onset of scarlet fever. The child was found lying on his right side; there was a constant spontaneous nystagmus toward the right and hearing tests showed no hearing in the left ear. The neck was slightly rigid, the temperature was normal and the mastoid was slightly tender. Lumbar puncture showed the spinal fluid to be under normal pressure but with a cell count of 180.

The diagnosis was suppurative labyrinthitis with beginning meningitis, and immediate operation was advised. Radical mastoidectomy showed a beginning coalescent mastoiditis with moderate softening of the mastoid cell partitions. Owing to the poor general condition of the child, further exploration of the labyrinth was postponed.

The next day, April 18, the temperature was elevated to 100.4 F., the neck was more rigid and lumbar puncture showed a definitely cloudy fluid with 2,900 cells but no organisms. A transfusion of 200 cc. of whole blood was given in the afternoon, and the labyrinth was opened in the evening by removing the stapes and the promontory connecting the oval and round windows. The following day, April 19, there was no longer stiffness of the neck, the spinal fluid was clear with a cell count of 203 per cubic millimeter, and the child was much improved. Two days later, April 21, the last lumbar puncture showed only 78 cells in the spinal fluid.

On April 24 weakness of the left facial nerve was first noted. April 25 the temperature rose abruptly from 99.2 to 105 F. The child was alert and made no complaints but appeared pale and emaciated, and the spleen was enlarged to 4 cm. below the costal margin. A transfusion of 200 cc. of whole blood was given. For three weeks an irregular fever persisted in spite of another transfusion, scarlet fever antitoxin and general supportive therapy. Except for a persistent secondary anemia, palpable spleen and gradually increasing emaciation, there were no other symptoms. Repeated blood cultures were positive for *Streptococcus haemolyticus*.

3. Eagleton, W. P.: Otitic Meningitis, *J. A. M. A.* 87:1544 (Nov. 6) 1926.

psychic elements the physician injects into the patient's mind when he injects the parenteral product into the patient's body. To justify ten, fifteen or twenty-five injections in ten, fifteen or twenty-five alternating or consecutive days, the physician must of necessity inject into the patient's mind that it is a "new" and "good" if not an "excellent" or "superior" method of treatment; "that eminent physicians the world over, abroad and in this country, have published favorable reports of its use," "that shortly after instituting the injection treatment a full diet can be tolerated" and so on. The injection of these and similar ideas into the patient's mind plus the additional encouragement that the patient receives from his physician during the more regular and frequent visits—these to my mind explain more than anything else the favorable results of parenteral therapy when favorable results occur.

2. *The Intermittent Nature of the Disease.*—The life history of ulcer is characterized by symptom-free intervals and relapses (remissions and recurrences). Spontaneous symptom-free intervals are not uncommon. Not all individuals with peptic ulcer are under medical supervision, nor do all patients who know they have

Fig. 3.—Dog died fifty-five days after operation; 112 cc. of larostidin (4,480 mg. of histidine monohydrochloride) had been given. Note depth of ulcer and also site of perforation.

peptic ulcer and who have been previously treated report to their physicians with every relapse they experience. Spontaneous symptom-free intervals may therefore occur during or immediately following parenteral therapy.

3. *A Nonspecific Protein Reaction.*—It is thought that local cellular injury leads to the production and absorption of proteins affecting favorably the chronically inflamed locus (the ulcer) by stimulating leukocytosis, mobilizing immune bodies, dilating capillaries, and the like.

4. *Nonspecific Desensitization.*—It is thought that the effect of parenteral therapy is one of nonspecific desensitization. A number of substances have been demonstrated to have this property.

5. *A Nonspecific Action on the Sympathetic Nervous System.*—This in some way influences the nervous control of the ulcer area, inducing hypomotility and hypoperistalsis.

In reply to a questionnaire sent to the members of the American Gastro-Enterological Association, the majority of opinion seems to favor the view that whatever benefit may accrue to the patient by parenteral treatment is of psychic origin—a change in type of treatment and something different than before.

#### CONTRAINDICATIONS

Injection treatment should not be given to patients having:

1. Gastric ulcers suspected of malignancy.
2. Ulcers with high grade obstruction.
3. Gastric ulcers prone to hemorrhage or bleeding.

#### EXPERIMENTAL DATA ON HISTIDINE (LAROSTIDIN): PRELIMINARY REPORT

The Mann-Williamson operation (diverting the duodenum into the terminal ileum, and anastomosing the stomach with the jejunum) produces ulcer in at least 95 per cent of dogs. Weiss and Aron of Strasbourg performed this operation on three dogs. They gave daily injections of histidine and reported that none of the three developed ulcers. Two control dogs, however, did develop ulcers after operation. From this and certain clinical results, Weiss and Aron reasoned that peptic ulcer is the result of histidine deficiency.

Saltzstein, Glazer and I are repeating the experiments of Weiss and Aron. The Mann-Williamson operation has so far been performed on twelve dogs. These dogs received 1 cc. of histidine twice daily (80 mg. per day), starting the day before or within two or three days following the operation.

Six of the twelve dogs have already died. Five showed definite jejunal ulcer, two of them with perforations. (One died twelve days after operation, the others from twenty-nine to fifty-five days after operation.) The sixth dog (death nineteen days post-operatively) showed intense inflammatory changes in the mucosa of the jejunum just distal to the anastomosis, which may be interpreted as early ulcer, though no frank erosion was present. Dr. Plinn F. Morse, pathologist at Harper Hospital, reported the gross and microscopic changes.

Six dogs are still living (from twenty-one to seventy-five days after operation). They all show blood in the stools, loss in weight, intermittent loss of appetite and occasional vomiting. These are the usual clinical signs of ulcer in these animals.

We therefore have not been able thus far to corroborate the original experiment of Weiss and Aron. In our hands ulcers have regularly followed the Mann-Williamson operation though the dogs received daily injections of histidine. This report is only preliminary. The experimental work is being continued. A more detailed report on a larger series of dogs will be given in a subsequent communication.

The accompanying illustrations show the gross appearance and photomicrographs of jejunal ulcers found in Mann-Williamson dogs that have received daily injections of histidine after operation.

#### SUMMARY

A series of 291 cases were observed during 1,019 ulcer attacks for comparative results obtained with the diet-alkali, parenteral and surgical methods of treatment in peptic ulcer. In ambulatory management the diet-alkali regimen was found satisfactory in 80 per cent of the attacks treated. Private patients, as a whole, respond more satisfactorily to ambulatory diet-alkali management than do clinic patients. Patients with acute ulcers show a higher percentage of symptom-free intervals than do patients with chronic ulcers. The best results were obtained in the private patients with acute ulcers. In the chronic group parenteral therapy

7. Sandweiss, D. J.; Saltzstein, H. C., and Glazer, W. S.: The Value of Histidine in Prevention of Experimental Ulcer in Dogs. *J. Digest. Dis. & Nutrition*, to be published.

Immediate operation was undertaken that evening. The first operation was found to have been incomplete, with many infected cells remaining in the upper third of the mastoid in the vicinity of the labyrinth. These were removed, a radical mastoidectomy was performed and the labyrinth was opened through the promontory, oval and round windows.

The following day, June 7, the patient was definitely better, with less headache, less stiffness of the neck and a lower temperature. For eight days he seemed fairly well except for slight headache at times with persistent fever around 101 F. and with at no time complete freedom from slight neck rigidity. A second lumbar puncture revealed 1,800 cells, half lymphocytes and no organisms. The patient repeatedly stated that he did not expect to get well.

The morning of June 14 a very severe headache came on acutely, boardlike rigidity of the neck rapidly developed, and

Nine days after operation the lumbar spinal fluid was clear and yellowish, with 180 cells, 65 per cent lymphocytes and no organisms on smear or culture.

Two weeks after operation the lumbar fluid was crystal clear with 90 cells, all lymphocytes, and no organisms, and two days later the patient was discharged feeling quite well except for weakness and emaciation.

One month after operation a plastic operation was done on the external canal and postaural wound and two months after operation the ear was dry, the postaural wound healed and the patient went back to work.

When seen June 6 this patient had a localized meningitis. Drainage of the focus (the labyrinth) resulted in temporary improvement, but some localized meningitis persisted, as evidenced by fever, slight headache

Chart 2 (case 5).—Temperature curve in localized meningitis on admission with temporary improvement after drainage of the focus in the labyrinth; generalized meningitis, June 14, with 5,200 cells, abundant organisms on smear and culture in the spinal fluid. Recovery following incision of the dura and drainage of the basal cisterns.

the Kernig sign was strongly positive for the first time. At noon the patient had a chill, followed by a rise in temperature to 102 F. In the afternoon he was irrational and in considerable pain from the headache. A lumbar puncture revealed 5,200 cells, nearly all polymorphonuclear leukocytes, and organisms were found in abundance on smear and culture. These proved to be nonhemolytic streptococci. By evening the patient did not respond, and his premonitions of the previous week seemed due to be fulfilled.

Immediate operation was decided on and was carried out that night. The posterosuperior angle of the petrous bone including the three semicircular canals was exenterated as far as the internal auditory meatus, exposing the cerebellar and temporal lobe dura with the superior petrosal sinus from the lateral sinus to the internal auditory meatus. The meatus was opened but no collection of pus was found and no cerebrospinal fluid escaped. The cerebellar dura was then incised just lateral to the internal auditory meatus, and a small rubber tissue drain was inserted an inch medially, thus draining the lateral projection of the basal cistern. A large quantity of cloudy spinal fluid gushed forth, soaking sponges, sheets and towels and dripping on to the floor. This flow continued for several minutes until probably several hundred cubic centimeters of spinal fluid had escaped. The patient's breathing, which had stopped three times during the course of the operation, necessitating artificial respiration, now materially improved. The drain was sutured to the dura and the wound packed lightly with iodoform gauze.

The first day after operation the patient was conscious, the headache was much better, the rigidity of the neck was less marked and the temperature did not exceed 99.6 F. Profuse drainage of cerebrospinal fluid through the iodoform gauze required frequent changes of voluminous overlying gauze dressings, and even then the pillow and bed clothes were soaked with the spinal fluid.

The second day after operation the escaping spinal fluid contained 310 cells and 60 per cent lymphocytes, but with abundant organisms on smear and culture.

The fourth postoperative day the flow of spinal fluid ceased, the headache was gone and the rigidity of the neck had disappeared. The drain was removed without the escape of any fluid. The temperature reached normal and stayed normal from this time on, except for occasional rises to 99 F. There was no further headache, stiffness of the neck or sense of impending death.

and slight stiffness of the neck. June 14 the infection broke through the barriers of the localized meningitis and generalized meningitis set in. This was promptly drained at the point of entry, with immediate and progressive improvement. By the fourth day the localized meningeal reaction had walled off the drainage tube from the rest of the cerebrospinal spaces so that it was removed without the escape of any further fluid.

The fact that this patient recovered at all must be attributed not only to the surgical procedure but to the factors of increased resistance of the host and decreased virulence of the invading organism, since the onset of the otitis media preceded the generalized meningitis by two months.

#### SUMMARY

A series of five consecutive patients with otitic or nasal sinus meningitis recovered after treatment according to accepted principles. These principles consist in the earliest possible diagnosis of meningitis by spinal fluid examination at the first suspicions of meningeal invasion, the cell count being the important consideration. A sharp differentiation must be made between localized meningitis, with increased cells but no organisms on smear or culture and with a normal sugar determination, and generalized meningitis, with organisms on smear and culture with diminished or absent spinal fluid sugar. As long as the meningitis is localized, treatment should be confined to thorough surgical drainage of the focus in the ear or sinus. Occasionally a few organisms may be found on smear but not on culture, and here also simple drainage of the suppurative focus may suffice to produce a cure. The prognosis of localized meningitis is good if it is promptly recognized and dealt with.

Once a generalized meningitis has developed, incision and drainage of the dura at or near the point of entry of the infection may be considered,<sup>3</sup> forced drainage of spinal fluid by the method of Kubie<sup>4</sup> may be

4. Kubie, L. S.: *Ann. Otol., Rhin. & Laryng.* 43: 692-701 (Sept.) 1934.

been overlooked or neglected. By the combination of the knowledge obtained in these studies, physicians can arrive at a satisfactory solution to most problems in the care of ulcer patients. I refer first to the work of Fenton B. Turck, who demonstrated the experimental production in dogs of ulcers typical of human gastric ulcer following the intravenous injection of extracts of dead tissue. He gave the name of cytost to the substance he felt was responsible for producing the area of focal necrosis causing the ulcer. Later Rosenow demonstrated the relationship between focal infection and ulcer, which has been so conclusively confirmed by clinical experience, although actual migration of bacteria from focus to stomach is questionable. Perhaps the cytost absorbed from the dead tissue in the focus is the etiologic factor, or perhaps allergy is the explanation. Thirdly, Cole's researches into the life history of ulcer have demonstrated that single gastric ulcers are not due to erosion of the mucosa but start like boils beneath the mucosa and break outward through it, that they heal spontaneously and rapidly and that recurrent attacks of ulcer symptoms are due to new ulcers. Intractable ulcers are complicated ulcers which have perforated or nearly perforated and which

Fig. 5.—Dog died forty-five days after operation; 79 cc. of larostidin (3,160 mg. of histidine monohydrochloride) had been given. Jejunal ulcer perforated into small intestine.

cause cicatrices, exudates or adhesions with resulting deformities. Such ulcers produce persistent symptoms and frequently require surgical treatment or they may be malignant ulcers from the start, showing no tendency to heal and requiring early operation. A simple ulcer requires only palliation of its symptoms and removal of all possible causes to prevent occurrence of future ulcers.

DR. SARA M. JORDAN, Boston: The treatment of ulcer cannot be considered from the etiologic basis because physicians are not united as to the etiology. There isn't enough information to give any firm foundation on that, but a therapy can be adopted that is based on logical, if not on etiologic, grounds. The purposes of treatment of ulcer are twofold: (1) to promote complete healing and (2) to prevent recurrences, to maintain that complete healing. How is complete healing promoted? Physiologic studies, which Ivy has reported so often, indicate that there are two things to combat, spasm and acid. Spasm is combated by rest, diet and the omission of irritants, and by something else which people call psychotherapy and which, in lieu of a better word, may continue to be called that. Acid is combated by all those measures, rest, diet and psychotherapy, plus some chemical aid. Where does larostidin fit into this picture? It certainly does not give the patient rest or make any changes in the diet. Does it influence the psychotherapy? Physicians who have had the same experiences

as I have often come to an impasse with the patient. One comes to the point at which the patient is not doing well and one of two things, from the psychotherapeutic point of view, is necessary; either one reviews the whole situation and stresses the necessity of continuing the present treatment and doing it still more carefully, or one introduces some new element into the therapy. I suspect that the cases in which larostidin has helped have been those cases. In my limited experience I have found it an adjuvant in relieving intractable pain temporarily, but temporarily only. I believe that has occurred because it introduces some new element into the psychotherapy of the situation. I do not believe that it maintains complete healing or has anything to do with that, and unless these ulcer patients can be segregated or transported into some ulcer-proof world, which is impossible, one will have to continue to combat spasm and acid as long as that patient lives, because the life history of the ulcer ends only with the life history of the individual.

DR. GEORGE B. EUSTERMANN, Rochester, Minn.: Treatment of any disease in which knowledge of etiology is still lacking or incomplete is necessarily empirical. Biologists explain that there are intrinsic and extraneous factors operative in the genesis of disease. The intrinsic, that is, the hereditary or constitutional, factor is not under control, and the extent of the rôle it plays other than conditioning the organ system to be involved is not measurable. The extraneous factors are to a large extent controllable under proper circumstances. Ulcer is essentially a disease of civilized people and is of psychosomatic nature. Infection, trauma and certain toxic or irritant products at times play a direct, prominent rôle, but such factors per se do not explain the genesis of the great majority of the lesions. Physicians are prone to consider too exclusively the extraneous factor. If the experiences of the past are any criterion, parenteral methods of treatment which have been and are now in vogue are doomed to fail. The *raison-d'être* for the choice of ingredients employed rests on a highly theoretical basis. Any form of treatment that is so simple and which requires so little self discipline on the part of the patient would appeal to the majority of physicians and certainly to the patient himself. I freely predict that the problem is not such an easy one. Treatment with larostidin, for example, occasionally produces a gratifying result in patients ineffectively or incompletely treated by other methods. I have not had an opportunity to follow such cases long enough to determine how permanent the results will be; but such occasional good results would not move me to advocate the adoption of any particular parenteral method of treatment to the exclusion of the orthodox method thoroughly and intelligently carried out. While experimental research has added much to our knowledge concerning various phases of ulcer, I doubt whether it has solved the riddle of the actual genesis of the disease in man. In the elucidation of therapeutic problems, however, observations on animals with experimentally produced chronic peptic ulcer have been made. On the basis of a procedure carried out by Reed and Ivy with gastric mucin as a prophylaxis in dogs receiving toxic doses of cinchophen, Stalker of the Mayo Foundation (unpublished data) investigated the therapeutic value of various preparations in a large number of dogs. All the control dogs developed chronic cinchophen ulcer indistinguishable from ulcer in man in an average of thirty days. Fifty per cent of the dogs getting mucin in the same manner and comparative amount that it is given to patients developed an ulcer. Every dog getting milk alone developed an ulcer but not a severe one. Dogs receiving larostidin developed a typical chronic ulcer in every instance. In not a single dog on the diet-alkali regimen did a chronic ulcer develop.

DR. ITALO F. VOLINI, Chicago: I wish to present some evidence as to the benefit of histidine in the treatment of peptic ulcer. I have promulgated the histamine theory in the production of peptic ulcer on the following evidence: 1. Stomach ulcers can be produced in rats by the injection of histamine. 2. Histaminase, the enzyme that destroys histamine, is absent in the stomach area where gastrin (histamine) is produced in greatest concentration. 3. Histamine injections produced in greatest concentration. 4. Early in the treatment with larostidin, symptoms may be exaggerated because increased histidine content available can be transformed into

h definite ulcer histories that it was not thought  
essary to urge x-ray examination because of the  
ense involved. About one sixth of the patients had  
one or more surgical operations for ulcer. About  
third had had hospital bed-rest managements on one  
more occasions. About three fourths of the patients  
been previously treated for peptic ulcer.  
The location of ulcer as found in the 291 patients is  
own in table 2.

#### DIETS USED

a) *Diet-Alkali Series.*—The diet used in the diet-alkali  
imen was as follows: for patients at rest in bed, hourly  
ings of milk and cream plus Sippy powders 1 and 2 with  
dual increase by the addition of eggs, cereals and the like  
et 1, original Sippy diet). Ambulatory patients were started  
milk, cream, soft boiled or poached eggs, strained cereals,  
amed soups, custards, cereal puddings, toast and butter,  
ided into six feedings a day (diet 2). If, at the end of  
ut ten days these patients continued to be symptom free,  
éed vegetables and fruits were added and the meals were  
ided into three a day with small feedings between meals  
et 3). Scraped beef, minced chicken and flaked whitefish  
re added to their diets (diet 4) from six to eight weeks  
er the beginning of dietetic treatment. Sippy powder 2 was  
ays prescribed, but Sippy powder 1, liquid petrolatum, hot  
ominal stupes, gastric lavages and antispasmodics were given  
y when indicated.

(b) *Parenteral Series.*—Patients starting on parenteral ther-  
y were advised to continue with the same diet followed prior  
parenteral treatment. Most of the patients treated with  
parenteral products were on a diet similar to diet 3 at the time  
atment was started. After becoming symptom free the  
ients were permitted to increase their food intake as they  
ased. No alkalis were given unless they had been taking  
alis before parenteral treatment was instituted.

#### RESULTS WITH AMBULATORY DIET-ALKALI THERAPY

Tables 3 and 4 present the results of diet-alkali  
management of 260 patients<sup>5</sup> (private sixty-two, clinic  
98) during 632 ulcer attacks (acute attacks 238,  
chronic attacks 394).

1. Varying immediate results were obtained, the best  
ults being observed in the private group with acute  
ulcer (94 per cent). The least satisfactory results were  
obtained with clinic patients having chronic ulcers  
(72 per cent, table 3).

2. Fewer relapses within one year were observed in  
private patients having acute ulcers (39 per cent). The  
reatest number of relapses occurred in the clinic  
patients with chronic ulcers (69 per cent, table 4).

3. Relapses within five years were least frequent  
among the private group with acute ulcers (65 per  
cent, table 4), and the highest in the clinic group with

5. The diet-alkali group includes a number of patients observed in  
the Harper Hospital outpatient department by Dr. C. D. Moll and in  
the North End Clinic by Dr. S. G. Meyers.

chronic ulcers (85 per cent, table 4). Despite these  
figures, it must be pointed out that ulcers of all types,  
in both groups, have a characteristic tendency to recur.  
Even in the most favorable group, i. e., private patients  
with acute ulcers, 75 per cent of attacks treated during  
a period of approximately ten years have already had  
relapses (table 4).

#### PARENTERAL VERSUS DIET-ALKALI THERAPY

The percentage of failure of diet-alkali therapy in  
ulcer patients of all types having been established, the  
next approach was to observe the results of parenteral  
therapy and to determine whether, and wherein, it is  
of value. The group selected for this study was the  
chronic ulcer patients, largely of the clinic group. This  
group had given the least satisfactory results of all  
types treated by the diet-alkali regimen. Table 5 shows  
the duration of ulcer symptoms in these series of  
patients at the time when parenteral treatment was  
begun. Tables 6, 7 and 8 show the immediate results;  
table 9 the late results with parenteral treatment in  
chronic ulcer patients (118 patients, 176 attacks).

1. The immediate results after vaccine, histidine and  
emetine injections are practically identical. Injections  
with distilled water produced similar results. The

TABLE 5.—*Duration of Ulcer Symptoms at Time of Treatment  
(Chronic Cases)*

Duration of Ulcer Symptoms at Time of Treatment	Vaccine	Laros- tidin	Synodal	Distilled Water	Diet- Alkali (Control)
Less than 5 years.....	7	4	7	4	10
5-9 years.....	11	13	7	4	10

Per cent with symptoms over 10 years.....	59	60	63	64	64

results do not differ appreciably from those obtained  
with diet-alkali therapy in similar types of patients  
(table 6).

2. The immediate results after parenteral therapy are  
identical for both the unselected series and the  
group that failed to respond previously to diet-alkalis  
(table 7).

3. Sixty-two per cent of the chronic ulcer patients  
who failed to respond to diet-alkali management  
became symptom free under parenteral therapy (table  
8). On the other hand, when parenteral therapy  
failed even after previous failure with diet-alkali

of the pancreas, punch biopsy or small incisional biopsy has been performed with immediate frozen section examination by the pathologist. This has been done with the idea that perhaps an early obstructing carcinoma of the pancreas may be recognized and resected in two stages, as recommended by Whipple, Parsons and Mullins<sup>1</sup> for the treatment of carcinoma of the ampulla of Vater. With punch biopsy of the liver the differentiation between hepatitis and carcinoma of the head of the pancreas also may be made, together with other conditions found at operation, such as a collapsed gallbladder and a nondilated common duct.

#### POSTOPERATIVE MORTALITY AND CAUSES OF DEATH

There were fifteen postoperative deaths in the thirty-four surgical cases, or a mortality of 44.1 per cent. Since two patients were found not to have a carcinoma of the pancreas or of the lower end of the common bile duct post mortem, the mortality for the operation in

Air present in the biliary system noted after ingestion of barium sulfate meal

malignant cases was actually 41.3 per cent, or thirteen deaths in thirty-two operations.

The causes of death were as follows: hemorrhage six cases, pneumonia two cases, and one case each of coronary artery disease, cholemia, shock, streptococcal meningitis, and intestinal leak. The latter case was the aforementioned choledochoduodenostomy for stricture of the common bile duct following a transduodenal resection of the ampulla of Vater. In this case there was no evidence of recurrent or metastatic carcinoma post mortem, one year after the primary operation.

Of the thirty patients who were thought to have carcinoma of the head of the pancreas at laparotomy, eleven died after operation, or a mortality of 36.6 per cent. Necropsy was performed on eight of the eleven patients. Four were found to have carcinoma of the head of the pancreas with either a single metastasis or multiple metastases. The presence of metastases to the liver and other organs occurred in spite of the fact that the duration of symptoms, particularly jaundice, was short—from four to six weeks. The remaining four

necropsies showed the following: (1) carcinoma of the common bile duct, (2) carcinoma of the ampulla of Vater, (3) cirrhosis of the liver and acute cholecystitis and (4) subacute yellow atrophy. As previously mentioned, the latter two conditions represent errors in the operative diagnosis and indications. Of the three patients who were not examined post mortem, one showed metastases on x-ray examination of the lungs.

#### FOLLOW UP: DURATION OF LIFE AFTER OPERATION

Nineteen patients in whom an operative diagnosis of carcinoma of the head of the pancreas was made were discharged from the hospital. Two of these patients were immediately lost from observation. Of seventeen patients with a partial or complete follow-up record, fourteen were known to be dead. All died between three months and one year following operation, except one patient who lived three and one third years. This patient, who was examined post mortem at another institution, was reported to have died of carcinoma of the stomach with liver metastases. The average post-operative duration of life in carcinoma of the head of the pancreas was seven months. This closely compares with the recently reported statistics of Judd and Hoerner (10.2 months)<sup>2</sup> and of Eliason and Johnson.<sup>3</sup>

Of the fourteen patients known to be dead, only five were examined post mortem. Three were found to have carcinoma of the pancreas, one carcinoma of the ampulla of Vater and the fifth patient carcinoma of the stomach with liver metastases.

Two patients were followed for eight months and then lost sight of. One of these cases, however, was probably not malignant, because on subsequent admission to the hospital the patient was thought to have hepatosplenomegaly. Of the three patients not known to be dead, only one is known to be alive. He has lived for twenty-six months after operation. At this time it is believed that he did not have carcinoma of the pancreas but probably was suffering from a chronic pancreatitis at the time of operation.<sup>3a</sup>

#### COMPLICATIONS

**Cholangitis.**—The question of cholangitis following biliary-intestinal anastomosis is a moot point. Some observers, notably Wangenstein,<sup>4</sup> Roeder,<sup>5</sup> Mason and Baker,<sup>6</sup> Graham and his associates<sup>7</sup> and many others have reported its occurrence as a great handicap to the operation. Other observers, as Kehr,<sup>8</sup> Bernhard,<sup>9</sup> and Mayo-Robson,<sup>10</sup> have found cholangitis a frequent

the chronic ulcer patients of both the private and the clinic group parenteral injections have their greatest field of usefulness (table 11).

#### STANDARD METHODS OF TREATMENT

To show what permanent effect, if any, the standard methods of treatment (diet-alkali management, vaccine<sup>6</sup> or surgery) have on patients (not on basis of attacks) over a long period of time, I have selected patients who have been treated for over five years for ulcer. Of the 291 patients studied 155 belong to this group (table 12).

1. Twenty-six patients (or 17 per cent, table 12) were symptom free five years or longer after treatment of their ulcer attacks. However, in fifteen of the twenty-six patients (approximately 60 per cent) ulcer relapses developed after a symptom-free interval of five years or longer.

6. The original series of patients treated with vaccine and referred to previously<sup>26</sup> was treated more than five years ago.

2. Only five patients (or 3 per cent of the total 155) are still symptom free from five and one-half to seven years after the first and only ulcer attack. Further follow up may show that these may also relapse. As an example, one in our series of 291 patients had an ulcer hemorrhage twenty-one years before and remained symptom free approximately eighteen years; during the last three years he has become refractory to treatment.

3. The small percentage of patients with five year (or longer) symptom-free intervals may be partly explained by the high percentage (76) of clinic patients in this series. This group of patients are of the lower economic and social strata, living under dietary handicaps. Environmental difficulties and inner emotional conflicts were frequently present and difficult to relieve.

TABLE 11.—*Field for the Usefulness of Ambulatory Diet-Alkali Management and Parenteral Therapy*

	Patients	Attacks	Symptom Free (Diet-Alkali)	Value of Parenteral Therapy (60% of Diet-Alkali Failures, Symptom Free)*
Private				
1. Acute.....	...	63	94%	3 or 4 out of 100 attacks
2. Chronic.....	...	78	83	11 out of 100 attacks
3. Total.....	62	141	88	7 or 8 out of 100 attacks
Clinic				
1. Acute.....	...	175	85	9 out of 100 attacks
2. Chronic.....	...	316	72	16 or 17 out of 100 attacks
3. Total.....	198	491	76	14 or 15 out of 100 attacks
Totals.....	260	632	79	12 or 13 out of 100 attacks

\* From table 3 we know the percentage of various types of ulcer patients responding to ambulatory-diet-alkali management. From table 7 we know the percentage of diet-alkali failures responding to parenteral treatment. If these experiences are general, one may determine the approximate value of parenteral therapy in the various types of ulcer patients. For example: given 100 private patients with acute ulcers (of less than five years' duration), 94 per cent become symptom free under ambulatory-diet-alkali management (table 3). Six per cent therefore fail to become symptom free. Approximately 60 per cent of these six diet-alkali failures (three or four patients) will respond to parenteral therapy. It would therefore not be advisable to give routine parenteral treatment to all the 100 patients when injection treatment is really indicated in only such a small percentage of the total.

TABLE 12.—*Follow-Up Results of One Hundred and Fifty-Five Patients Treated Longer Than Five Years*

Number of patients treated longer than 5 years	155	Symptom free 5 years or longer after treatment with:
1. Number of patients symptom free 5 years or over	26 (17% of the 155)	(a) Resection..... 1 (b) Gastro-enterostomy.... 6 (c) Suturing of perforation 1 (d) Hospital diet-alkali.... 6 (e) Ambulatory-diet-alkali. 12
(a) Number of patients symptom free 5 years or over and subsequently developed ulcer relapses	15 (60% of the 26)	(a) Resection..... 1 (b) Gastro-enterostomy.... 5 (c) Hospital diet-alkali.... 3 (d) Ambulatory-diet-alkali. 6
(b) Number of patients symptom free 5 years or over after treatment of their last attack and still symptom free	11 (40% of the 26)	(a) Gastro-enterostomy.... 1 (b) Suturing of perforation 1 (c) Hospital diet-alkali.... 3 (d) Ambulatory-diet-alkali. 6
2. Number of patients (included in 1b) who had only one ulcer attack in their lives and still symptom free 5½-7 years later	5 (3% of the 155)	(a) Suturing perforation... 1 (b) Hospital diet-alkali.... 1 (c) Ambulatory-diet-alkali. 3

#### INTERPRETATION

The reasons why only certain patients respond to parenteral therapy cannot be stated definitely. One or several explanations may be given. I prefer the first two of the following five:

1. *Psychic Factor*.—I am referring not only to the psychic factor on the part of the patient, to the knowledge that he is getting something "new" and "different" instead of the "same old diet and powders" (so well known to ulcer patients), but more especially to the

the appendix was found to be normal in appearance except for some old adhesions. Arising from the pelvis and extending into the right side of the abdomen was a reddish blue, tense mass having the consistency of a cyst rather than being firm like a fibroid tumor. This tenseness later was found to be due to edema, which was quite marked. The mass was a fibromyomatous uterus measuring 5 by 9 by 7 cm. The uterus, owing to the shape, size and location of the tumor, was twisted through a 60 degree angle at the isthmus. The fibromyoma was subserous and was in the right cornu, showing a large base that extended down into the muscle. The uterus was twisted toward the right and posteriorly, carrying the right round ligament and the base of the tube posteriorly and the left ligament and tube anteriorly. The tumor along with the congestion distorted the appearance of the uterus. Because of the existing pathologic condition a hysterectomy was performed and a simple appendectomy done.

The pathologic diagnosis was myofibroma of the uterus with several intramural nodules, in the midmenstrual phase.

The patient had an uneventful convalescence and was discharged March 15.

#### LITERATURE

The first record of torsion of the uterus was made in 1861 by Times of England. Since then there has been a gradual increase in the number of cases reported

The corpus uteri (A) is twisted at the isthmus through 60 degrees clockwise. The fibromyoma is shown posterior to the uterus. B, bladder. The left broad ligament, left tube and left ovary (C) have been pulled anteriorly with the right broad ligament (D) disappearing posteriorly.

in the foreign literature, with a few detailed studies reported in this country. Approximately 143 cases of axis torsion of the fibromyomatous uterus have been reported to date. We have been able to collect nine cases of torsion of a fibroid uterus reported in the United States, many more, however, being reported in other countries. Many errors in reports of the total number of cases may be explained by the fact that some authors exclude cases when pregnancy is associated while others include all types of axis torsion.

#### ETIOLOGY

Axis torsion of the uterus occurs more frequently in women over 40 years of age. The oldest patients on record are those of Bland Sutton,<sup>2</sup> Griffith and Semmelink, being 70 years of age.

The location and the size of the tumor have a direct bearing on the torsion. Most specimens show a fibromyomatous tumor weighing more than 2 Kg., the average weighing 5 Kg. The interstitial tumors are more prone to cause torsion if their location is in one cornu

or at least away from the midline of the uterus. It is quite evident that the leverage force is in this way eccentrically placed and increases the likelihood of torsion.

The true cause for rotation of the uterus has not been clearly decided. Piquand<sup>3</sup> and Vautrin point out that the left lumbosacral fossa is well filled with the sigmoid colon, whereas the right is empty, and with the growth of the fibroid tumor associated with the rise of the uterus in the pelvis the uterus falls toward the empty side. Only thirteen times in eighty-four cases was the torsion from right to left in one author's study. The acute torsion is probably due to some external force or to sudden muscular effort. Once the accident of torsion has occurred, the abdominal wall will supply enough spasm to increase the intra-abdominal pressure to the point of maintaining the error.

The point of torsion is fixed, occurring as a rule at the level of the uterine isthmus. The elongation of the isthmus may be so pronounced as to reduce this region to almost a cord. Mengert<sup>4</sup> has shown in his study of factors influencing uterine support that the ligaments above the uterine isthmus do not play a major rôle. The round and ovarian ligaments do not exert a great resistance to the mechanism of torsion, owing to gradual stretching with the growth of the fibroid.

#### SYMPTOMS

The clinical signs and symptoms must be considered from two points of view, depending on whether the torsion is acute or is a slow progressive, chronic procedure.

Patients with acute torsion present the general picture of distress comparable to strangulated hernia, to ruptured ectopic pregnancy or to a twist of the pedicle of an ovarian cyst. The onset is sudden, severe and dramatic, without prodromal signs, producing severe intense pain in the lower part of the abdomen, progressing to pallor and shock. After a few hours these signs and symptoms become less acute, only to return accompanied by a rise in the temperature curve, as evidence of some absorption from the tissue involved in the edematous and ischemic area.

During this short quiescent interval there are a number of valuable physical signs that may be elicited in an effort toward diagnosis of this sometimes called acute condition of the abdomen.

Bimanual examination will reveal the fibromyoma closely associated with the uterus, the entire mass being very firm, and manipulation will cause extreme pain. The cervix is usually found to be high in the vaginal vault and has been reported by some authors as being difficult to reach. All writers on this subject have thoroughly emphasized the fact that it is impossible to pass a catheter into the uterine cavity, and this is an excellent diagnostic sign. Few gynecologists would attempt the latter diagnostic procedure in the presence of acute torsion, for the patient is usually in a grave condition and surgical intervention is definitely indicated; however, this is a great aid in chronic torsion of the uterus.

Symptoms present in chronic torsion vary with the method in which the complication occurs. From a study of reports and histories given by these patients it seems most common for symptoms to come and go with free

was of value when patients failed to respond to diet-alkali management. In this group, parenteral therapy has its chief value as an additional method of treatment. The psychic factor, I feel, is greatly responsible for the favorable results when they occur. Hospital bed rest, when finances permit, produces the best results in chronic cases. Surgical treatment, though producing good immediate results, does not surpass those of other methods, all of which have a high percentage of relapses.

#### CONCLUSIONS

1. Approximately 90 per cent of the patients with ulcer attacks treated in private practice became symptom free after careful dietetic-alkali management, compared with approximately 75 per cent of remissions obtained in the charity clinic groups. Greater financial worries, lack of cooperation, social maladjustments, and improper and perhaps insufficient food probably explain the lower percentage of remissions in the clinic series. In the latter group environmental difficulties and inner emotional conflicts were frequently present and difficult to relieve.

2. Of those who were given parenteral injections after failure to respond to the diet-alkali regimen, approximately 60 per cent became symptom free after injections of either stock respiratory vaccine, larostidin or synodal. In twenty-two patients, injections of distilled water were used. Comparable results have been obtained.

3. In my opinion it is not the histidine in larostidin or the emetine in synodal or the dead bacteria in vaccines that produce remissions in these cases. Approximately only half become symptom free. Also, injections of distilled water produced similar results. Remissions produced may be explained as psychic effects, added confidence in "something new" instead of the "same diet and powders" (so well known to ulcer patients), greater encouragement due to more frequent visits to physician or nurse as well as persistence in treatment.

4. Some patients do not respond to any form of medical therapy. When, however, the tensional states of these patients are relieved (environmental difficulties or emotional conflicts) an almost miraculous response occurs at times even without any other form of treatment. "Management of the patient" in addition to "treatment of the ulcer" must be stressed. Tensional states to my mind deserve greater attention than the ulcer per se, unless complications intervene.

5. Most of the patients treated in this series returned with recurrences of symptoms after treatment with one or another or several of the methods described. When remissions were produced by treatment, the symptom-free interval was longest after diet-alkali treatment. The short duration of remissions and the high percentage of recurrences after parenteral therapy probably result because of more rapid increase in diet. The patients on diet-alkali management were schooled in the essential dietetics of their treatment; those treated with the parenteral method were not so educated, had a more liberal diet and suffered early recurrences.

6. When a symptom-free interval results (with or without parenteral therapy) a restricted diet must be continued. The patient thereafter should be periodically observed and periodically instructed as to "what to eat, how to eat and how to live." This may tend to delay relapses and prevent complications. Attention should then also be given to coexisting disorders, as definite foci of infection, mild hyperthyroidism, tensional states, and so on.

7. Of 155 patients treated (medically and surgically) and observed longer than five years, only five (3 per cent) are still symptom free from five and one-half to seven years after their first and only ulcer attack. This speaks unfavorably for the lasting benefit to be derived from any form of ulcer therapy. It appears that, at the present state of our knowledge, all we can hope to accomplish and should aim for are: (a) to relieve symptoms, (b) to delay relapses and (c) to prevent complications.

8. The parenteral method is not indicated in the routine treatment of peptic ulcer. It may be used only in those patients not responding to the diet-alkali regimen and only in association with but not in place of the usual bland diet. There is only slight difference between the results obtained by the injections of the various products mentioned. If one product fails to produce a remission, another may be tried. At present there is no parenteral product specific for peptic ulcer.

Fig. 4.—Section of ulcer in figure 3.

9. Since we have been using the parenteral method of treatment fewer patients have been hospitalized for medical bed rest treatment and still fewer patients were operated on. We now hospitalize only those patients who have hemorrhages, high grade obstruction, penetrating ulcers, perforation or gastric ulcers suggestive of malignancy. Such patients should not be given injections.

10. We (Sandweiss, Saltzstein and Glazer) have been unable, thus far, to corroborate the experimental work of Weiss and Aron of Strasbourg that injections of histidine (larostidin) protect dogs from peptic ulcer following surgical duodenal drainage (Mann-Williamson operation).

9739 Dexter Boulevard.

#### ABSTRACT OF DISCUSSION

DR. A. F. R. ANDRESEN, Brooklyn: It is time that something should be done to check the exploitation of the doctor and his patients by pharmaceutical houses advocating parenteral injections of various unproved medicaments, intragastric and intraduodenal instillations of modified foods or of alkalis or alkaline earths, and the oral administration of noxious substances or freak combinations. Three experimental researches of fundamental value in the approach to the ulcer problem have

multiple adenomas, (2) polyps found in association with hyperplastic tuberculosis, (3) polyps found in association with old strictures of the colon, and (4) polypoid conditions of the mucosa which result from ulcerative colitis. The terms polyposis, polypoidosis and diffuse adenomatosis are not offered as a classification but have been frequently used to designate the adenomatous

Fig. 1.—Second stage of colectomy: The mobilization of the colon is shown beginning from right to left by dividing the lateral parietal peritoneal attachments to the mesentery of the bowel, saving sufficient peritoneum for covering raw surfaces. The omentum is retracted upward with the stomach and is saved. a, kidney; b, peritoneum; c, omentum; d, transverse colon; e, descending colon.

The origin of the acquired or postinflammatory polyps is quite different and better understood. Wagner noted that small polyps appeared on the edges of healed ulcers of the colon, and Rokitansky observed that dysenteric ulcers were accompanied by polyps. He believed that the undermining ulcers produce a break in the mucosa, leaving an overhanging portion, which, being shut off by the regenerative process, forms a pedunculated polyp-like tumefaction with smooth or irregular outlines. Struthers<sup>7</sup> and others have noted the relationship of polyposis with inflammatory conditions of the colon, particularly with chronic ulcerative colitis. The process of formation is assumed to be the same as in other inflammatory conditions of the bowel, with islets of mucous membrane being caught in the cicatrization of the healing process, resulting in outpouchings which terminate in polyps. The distribution of acquired polyps, principally those associated with chronic ulcerative colitis, starts more frequently in the rectum but may extend to involve the whole colon to the ileum. Although the etiology of postinflammatory and true polyps is accepted as being different, one must not forget that the former as well as the true polyps may undergo malignant change. Borgen<sup>8</sup> reported twenty-five cases of carcinoma which had developed in the presence of polyps secondary to the inflammatory reaction of chronic ulcerative colitis. Quite as interesting, Mayo and Wakefield<sup>9</sup> recently reported two cases of disseminated congenital polyposis in which all evidence of the polyps was destroyed in the segments of

bowel removed, following the implantation of chronic ulcerative colitis, probably as a result of the destruction and ejection of the mucous membrane.

A pathologic study of true polyps of the colon by FitzGibbon and one of us<sup>10</sup> has emphasized the potential malignancy of this condition and greatly influenced our method of treatment. On histologic examination the tumors were found to fall readily into three major divisions: polyps of group 1 were roughly nodular and invariably pedunculated. The pedicles were usually cylindrical, composed of connective tissue derived from the submucosa. The epithelium covering the pedicle and the growth and lining its crypts was unchanged from the standard regarded as normal; however, areas of slight hyperplasia and active inflammation secondary to the constant trauma were occasionally found. There was nothing about the tumors of this group to indicate that they were any more liable to malignant development than the normal intestinal mucous membrane.

Polyps of group 2 showed striking structural changes in both the epithelial and the connective tissue elements. The epithelial cells were hypertrophied, elongated and not completely differentiated, and they stained deeply. There was a complementary response in the connective tissue, which tended to spread out in a treelike formation. The epithelium in this group seemed to develop more rapidly than in the normal mucosal lining and in time was likely to throw off the bounds of restraint and assume an invasive and lawless career. This fact has been repeatedly verified by making numerous sections through the polyps. Many of the areas appeared normal, but not infrequently microscopic signs of malignancy were encountered. Some of the areas were no larger than 2 mm. in diameter. This group is often the source of malignancy of the colon.

Polyps of group 3 represented growths that were an accentuated form of group 2. The epithelium in this process had been arrested at so early a state that differentiation was very slight and the cells attained only the most rudimentary characteristics of the normal intestinal mucosa. Polyps of this group ordinarily did not exceed the size of a split pea. The elementary epithelium proliferated so rapidly that the nodules approached cancerous change before the tumor had become large enough to be played on by the forces of peristaltic action, which is thought to be influential in elongating the tumors. Because of the high incidence of malignancy in this group, it is well to remember that these lesions have been found scattered throughout the intestinal mucous membrane.

Fig. 2.—Second stage completed: The ileostomy is shown in the right iliac fossa. The rectal stump including the lower part of the sigmoid just beyond the rectosigmoid junction is shown as well as coils of small intestine. The peritonealization is accurately completed. a, kidney; b, ileum; c, sigmoid.

histamine without rapid destruction of the latter. Histamine produces severe arteriolar spasm, profound capillary vasodilatation and increased capillary permeability. This action is seen best in urticaria produced by the H substances of Lewis. Histamine stimulates gastric secretion, increasing the acid and water content in addition to producing increased motor activity. Histidine is transformed into histamine by the removal of carbon dioxide. Histidine injections may stimulate production of the histaminase. Histaminase destroys histamine. Histaminase action is demonstrable in patients treated with histidine by: A. The effect on the gastric secretion. There is a decrease in both the amount and the acidity titer in fasting and histamine stimulated gastric juice. The repeated or second histamine injection shows this decrease in the larostidin treated ulcer but not in (1) the normal individual, (2) the untreated ulcer patient, (3) the alkali treated ulcer or (4) the Pavlov pouch secretion juice in the dog. B. The marked sedative effect on gastric motility demonstrated by kymographic tracings of stomach contractions in the larostidin-treated ulcer patients. C. The favorable response of urticarial lesions and hay fever symptoms to histidine injections, which occurs in many cases. I assume that these and other allergic and anaphylactic reactions are due to histamine or histamine-like substances. Theoretically, histaminase production which destroys histamine rapidly should ameliorate these syndromes.

DR. RUSSELL S. BOLES, Philadelphia: In the discussion of Dr. Jordan's paper I suggested the possibility of peptic ulcer being a form of peripheral vascular disease. I am impressed with the work of Dr. Sandweiss and I do not believe the results should be too abruptly attributed to a psychotherapeutic effect. Histidine likewise has a definite vasodilating action. Bismuth subcarbonate when given orally becomes bismuth subnitrate and recently has been advocated in the treatment of hypertension because of its vasodilating effect. I can thus see the possibility of an explanation of Dr. Sandweiss's results in that histidine, acting as a vasodilator, may bring about a hyperemia in the ulcer-bearing area and thereby an improvement in the ulcer symptoms. Certainly, as Dr. Eusterman has said, the orthodox treatment is fundamental. Dr. Jordan says "there are ulcers and ulcers." That is true. Ulcers in early life may reasonably be due to thrombosis of infectious etiology and as such may heal even despite various methods of treatment; other ulcers later in life may be of purely arteriosclerotic origin and as such are more refractory to treatment. I don't believe there is one of us who doesn't prohibit the use of tobacco in ulcer patients. Why is the use of tobacco harmful in ulcer? Is it because of the effect on secretion? Tobacco is a powerful vasoconstrictor and, by prohibiting it, we probably allow a certain amount of normal vasodilatation to take place at the site of the ulcer. Hypotension, as Dr. Gorham said, exists in many of these cases but that does not preclude their having arteriosclerosis or other vascular disease. It is possible that the author's results may be due to the relaxation of the arterial spasm that probably exists in ulcer cases.

DR. JOHN H. FITZGIBBON, Portland, Ore.: Several years ago a patient whom I was treating for ulcer on Sippy management came to the office with a syphilitic rash. He was referred for treatment to a man who gave him rather intensive treatment and a few weeks later returned to me asking if I thought it necessary for him to take alkali while he was receiving the neoarsphenamine injections. I asked "Why not?" He said "I have no free hydrochloric acid in my stomach following these injections." He was aspirating his stomach every night and testing for acid. As I had never heard of such an effect from neoarsphenamine, I checked up his statement. Following every injection of neoarsphenamine he was free of hydrochloric acid for a few days. I discussed the matter with the department of physiology at the medical school of the University of Oregon and Dr. Wilmot Foster started work on the problem. A series of dogs with pouches were examined. Following varying doses of neoarsphenamine, rather interesting observations were made. It was found that both the amount of secretion and the chloride content decreased in proportion to the amount of neoarsphenamine injected. Regarding the general treatment of ulcer, I think that any physician in practice long enough to have many failures realizes that the treatment of ulcer consists of two parts: first, healing the ulcer or removing it; second, a life-

long effort to prevent recurrence. The injection of greatest value in the treatment of peptic ulcer is injection of common sense and conservatism, using hobbies and pet tricks when desired but accompanying them with the good old standardized and conservative methods that have been proved to be of value for so many years.

## STATUS OF CHOLECYSTOGASTROSTOMY IN OBSTRUCTIVE JAUNDICE

DUE TO CARCINOMA OF THE HEAD  
OF THE PANCREAS

GORDON D. OPPENHEIMER, M.D.

AMEIL GLASS, M.D.

AND

FRANK NETTER, M.D.

NEW YORK

In order to evaluate the results of biliary intestinal anastomosis, particularly in cases of carcinoma of the head of the pancreas, a study was made of thirty-four surgically treated patients who were in the ward services during the ten years between 1926 and 1935.

These patients were operated on because of jaundice. Their ages varied between 24 and 70 years, the average age being 50. The incidence of male and female patients was as 6 to 1; i. e., twenty-nine men and five women. The history was usually one of slowly increasing, painless, obstructive jaundice with pruritus, weakness and loss in weight. The preoperative diagnosis was carcinoma of the head of the pancreas or carcinoma of the common bile duct below the cystic duct or carcinoma of the ampulla of Vater.

### DIAGNOSIS AT OPERATION

In thirty patients the diagnosis at laparotomy was carcinoma of the head of the pancreas. In four patients the diagnosis was as follows: carcinoma of the common bile duct one case, carcinoma of the ampulla of Vater two cases, and stricture of the common bile duct following a previous duodenotomy and resection of a carcinoma of the ampulla of Vater one case. All the patients had a suture cholecystogastrostomy performed except the latter patient, in whom a choledochoduodenostomy was done.

In all the cases the gallbladder was noted at operation to be tense or distended, and in only one case was a stone present in the gallbladder. These observations are confirmatory of "Courvoisier's law."

### ERRORS IN OPERATIVE DIAGNOSIS AND INDICATION

Of the thirty cases diagnosed as carcinoma of the head of the pancreas at operation, all with the exception of five were found to show this condition, or carcinoma of the common bile duct below the cystic duct or carcinoma of the ampulla of Vater. These five cases presented the following conditions: (1) cirrhosis of the liver, (2) subacute yellow atrophy (postmortem examinations following operation), (3) carcinoma of the stomach with liver metastases (found at later postmortem examination), (4) hepatosplenomegaly and (5) chronic pancreatitis (subsequent clinical diagnoses). The operation of cholecystogastrostomy was probably not indicated on the basis of the subsequent examination in the first four of the aforementioned cases. This is a percentage error for the operation of 13.3.

During the past year in doubtful cases of obstructive jaundice in which the lesion is thought to be in the head

From the Surgical Services of Dr. Edwin Beer and Dr. Ralph Colp, the Mount Sinai Hospital.

allow for marked general improvement. The patient's weight usually registered an appreciable increase, the secondary anemia was frequently overcome without aid of transfusion, and the patient's general health was more sturdy and able to withstand the shock of a major surgical procedure.

With the colon at rest and peristalsis at low ebb, the infection and some of the polyps readily subside and make the colon more easily manageable when resection is undertaken. Otherwise the thick-walled, infected bowel is highly friable, is difficult to suture satisfactorily and often may be the source of a fatal peritonitis when manipulated. An optimal period of about six months is desirable for an ileostomy. In addition to allowing for favorable changes in the colon, the ileum is given time for necessary adjustments vital to restoration of fluid balance. At first the substance issuing from the ileostomy is liquid and more or less continuous, but in time it is altered in consistency to a semisolid state. Whether the ileum dilates sufficiently to take over some of the functions of the colon or whether, as Wakefield suggested, the kidneys compensate in maintaining the electrolytic balance of the body, the benefits of the procedure preceding total colectomy or subtotal colectomy are definitely established. Any artificial stoma of the gastro-intestinal tract will meet with objection from the patients; but when the benefits of such a procedure are enumerated their sanction is readily secured, particularly when the inconvenience is temporary. With recent improvement and modification in the surgical attack on diffuse adenomatosis, the rectum is more frequently saved than destroyed and provides a site for subsequent anastomosis of the ileum, which dispenses with the ileostomy as a permanent fixture.

An ileostomy for adenomatosis is best performed by dividing the terminal ileum, closing the distal end and bringing the proximal end out through a split muscle incision in the lower right quadrant of the abdomen. The lumen is no longer occluded by a clamp but accommodates a Pezzar catheter, which is inserted and secured by a purse-string suture. Drainage is immediately established and distention, cramps and the associated discomforts of an obstructed bowel are prevented, while fluids are administered by mouth without delay.

Several months, usually six, is the optimal time after the ileostomy has been made to put into execution plans for the removal of the colon. A shorter time is not adequate for rehabilitation and reduction of the infection and edema, and likewise a longer time is contraindicated, since it may allow for malignant change. At one time we did a total colectomy with removal of the rectum, having a permanent ileostomy in all cases. It was a bearable and often comfortable appendage which could be countenanced, but it was never as convenient as the normal mechanism with continence. The introduction of surgical diathermy made possible modifications in technic, combining conservatism with effective treatment and preservation of the rectal control. The rectum to the rectosigmoid juncture has come within the range of attack through the proctoscope. The polyps in this field can be destroyed by fulguration and this segment of bowel with its sphincteric mechanism salvaged for anastomosis with the ileum. This can be accomplished at intervals during the existence of the ileostomy while time is being allowed for the patient's general improvement as well as reduction of the infection and edema of the colon.

The removal of the colon may be undertaken by one of several steps after the ileostomy has been performed and the rectal polyps completely destroyed by fulguration. Some advocate the anastomosis of the ileum to the rectal stump before doing a subtotal colectomy. On the other hand, there are those who believe that a reversal of this plan by doing the colectomy first, allowing for several weeks or months to pass before anastomosing the ileum to the rectal stump, is the better procedure.

In any individual case the order may vary because of specific indications, but in a general way we prefer to do an ileostomy, waiting six months during which time the polyps are destroyed, and then doing a subtotal colectomy and finally the anastomosis at a subsequent operation. Then, when one is assured of the adequate function of the anastomosis, the ileostomy may be closed under local anesthesia.

Recently it has been proposed to leave longer segments of the colon, the sigmoid and descending colon above the site of proposed anastomosis with the ileum. It is difficult to see the advantages of this, and there are several apparent disadvantages to such a procedure. The added loop or segment proximal to the anastomosis is unnecessary as a reservoir, and, of greatest significance, it is beyond the reach of the investigating proctoscope or sigmoidoscope, which is the only means of maintaining strict observation over this field, which of course is subject to recurrent polyp formation.

The short rectal stump, as we advocate, supplies adequate storage space with the spacious ampulla of the rectum to serve as a reservoir to permit the patient the convenience of two or three stools a day under control. This short colonic stump is well within the range of investigation and can be frequently checked for the presence of any polyps, and treatment in the instance of recurrence can be rendered by fulguration.

The subtotal colectomy is usually accomplished through a long left rectus incision and the colon is removed from right to left. In mobilizing the right colon, one cuts the outer leaf of the peritoneum in the bloodless area, rotates the bowel mesially, and ligates the blood vessels rather close to the bowel wall as they appear. It is helpful to accomplish the peritonealization of raw surfaces as the different segments of the bowel are mobilized.

The first mobilization of the colon goes to the hepatic flexure, where the retroperitoneal duodenum is identified and safeguarded against injury. From the hepatic flexure to the splenic flexure the step is a rather easy one if one leaves the omentum as a protection against infection and to be utilized in covering denuded areas. The splenic flexure is more difficult to mobilize, but by cutting the splenicocolic ligament and the lateral parietal peritoneum along the margins of the descending colon one may rotate it mesially and get at the blood supply accurately. The dissection is carried on to the rectosigmoid, where the bowel is cut across and the lower end invaginated. The resected portion of the colon is removed in one piece and the peritoneum is closed over the raw areas.

The turning in of the lower end of the bowel is a procedure often fraught with considerable difficulty and danger. The bowel wall is frequently thickened and may be edematous, which makes it quite friable. Often if Payr clamps are applied the bowel will be cut across and peritoneal contamination will ensue. To prevent this misfortune, rubber covered gastro-intestinal clamps may be used and the bowel divided by the cautery between them.

complication but not enough to prevent them from performing the operation. Babcock,<sup>11</sup> DuBose<sup>12</sup> and Finsterer<sup>13</sup> have not seen cholangitis in their series. Gentile<sup>14</sup> has recently reported some interesting experiments, from which he concludes that cholangitis does not follow cholecystogastrostomy in dogs.

It would appear from a survey of the literature that cholecystogastrostomy is less liable to be followed by liver infection than cholecystoduodenostomy.

In none of the nineteen patients in this series was the complication of ascending infection evident either from the clinical course or from later postmortem examination. Interesting in this connection are the repeated roentgenograms of the patient with a probable pancreatitis.<sup>3a</sup> A complete visualization of the biliary passages by gas from the stomach was present on several examinations, and yet this patient did not present evidences of cholangitis.

There was one other patient not previously mentioned in whom the operation of cholecystogastrostomy was performed for persistent symptoms thought to be due to a chronic pancreatitis following a biliary peritonitis of unknown etiology. Three years later the anastomosis, which was small but patent, was disconnected and a cholecystectomy was performed. There was no evidence of cholangitis in this patient.

*Stenosis of Stoma.*—This complication was not found in any of our patients. Complete closure or stenosis may occur, however. Beer<sup>15</sup> found a complete closure in one case and an inflammatory stenosis in another. Parsons,<sup>1</sup> in his discussion on the radical treatment of carcinoma of the ampulla of Vater, describes a marked stenosis of a cholecystogastrostomy stoma due to subsequent contraction of a distended gallbladder.

It should be noted that, while closure or stenosis of a cholecystogastrostomy stoma can occur in the presence of a patent common bile duct,<sup>16</sup> it is obviously less likely to follow if the common duct is obstructed by a malignant condition or by operative ligation and section.

#### BENEFITS OF OPERATION

Of seventeen patients who survived operation and who were either partially or completely followed, ten were temporarily benefited by the operation, three were questionably benefited and four were not benefited. By benefited we mean decrease or disappearance of jaundice, loss of pruritus and pain, and gain in weight and general well being. In at least two patients in whom jaundice disappeared it reappeared later on.

#### INDICATIONS FOR CHOLECYSTOGASTROSTOMY

In general, the operation should be performed when there is a nonremovable obstructive lesion of the common bile duct below the cystic duct.

When the lesion is nonmalignant, as for instance obstruction due to stone or chronic pancreatitis, the anastomosis is compatible with life as attested by a large number of reports in which patients lived from three to thirty years.<sup>17</sup> While a cholecystostomy or choledochostomy may temporarily save a patient in the face of a constant nonmalignant obstruction, the discomforts and dangers of a biliary fistula are well known and are obviated by cholecystogastrostomy.

As a palliative procedure for carcinoma of the head of the pancreas or carcinoma of the ampulla of Vater, it is indicated because approximately 60 per cent of the surviving patients are temporarily benefited by being relieved of their icterus. It is also indicated because in a certain number of cases the differential diagnosis between a malignant and a nonmalignant obstruction cannot be made at operation. However, in the malignant cases the benefits of the operation are not of very long standing, since almost all patients die within one year, and usually within seven months. The operation should be performed in malignant cases in preference to cholecystostomy or choledochostomy because of its lower mortality, as shown by Cohen and Colp<sup>18</sup> in a study from this institution.

If an attempt at radical operation is made, the cholecystogastrostomy should be performed as a first stage procedure together with a gastro-enterostomy and ligation and division of the common bile duct below the cystic duct preparatory to removal of the head of the pancreas and adjacent duodenum for carcinoma of the ampulla of Vater, as suggested by Whipple, Parsons and Müllins.<sup>1</sup> This procedure should be performed, too, for an early carcinoma of the head of the pancreas. Concerning the latter, a discouraging feature is that metastases were already present in the cases of this series and in an early case reported by one of us,<sup>19</sup> even though the symptoms were of short duration.

941 Park Avenue.

## ACUTE AXIAL TORSION OF THE FIBROMYOMATOUS UTERUS

C. S. McMURRAY, M.D.

AND

HAMILTON V. GAYDEN, M.D.

NASHVILLE, TENN.

Occurrence of torsion in the fibromyomatous uterus is sufficiently rare and the complications are of such gravity that it would seem wise to report even a single new case. A survey of the literature reveals very few reports from this continent and no exhaustive work since the report of Peightal<sup>1</sup> in 1929.

#### REPORT OF CASE

Miss G. S., a nullipara, aged 34, admitted March 1, 1936, complained of "severe pain in the abdomen" of one week's duration. The cramplike pain developed in the right lower quadrant of the abdomen and felt like a weight pulling down. This pain was similar to, but more severe than, the pain she had been experiencing the past three years prior to her menstrual periods. The menstrual history had been quite normal and regular until the month previous to admission. At the time of the onset of the pain the menses were seventeen days past due.

The Wassermann reaction was negative. Urinalysis was negative. White blood cells numbered 13,050. Coagulation time was three and one-half minutes.

On physical examination the patient was well nourished and rather obese. There was a general spasm and rigidity of the abdominal wall, which was more marked in the right lower quadrant. The uterus could not be distinctly outlined because of tenderness and rigidity in an obese abdomen. A diagnosis of an acute appendicitis was tentatively made and the patient was prepared for immediate operation.

Through a midline suprapubic incision a small amount of blood-tinged fluid escaped. When the peritoneum was opened

A brother, aged 13 years, whose history will follow, has the same disease. Another brother died of pneumonia at the age of 7 months about twenty years ago, having had at the time drooping eyelids and limitation of movements of the eyes, which were first noted at 3 months of age. Another brother, now 18 years old, had drooping eyelids at the age of 2 during an attack of whooping cough and now has recurrences of lagophthalmos with any severe infection but is otherwise quite strong and well. No other members of the immediate or near family are similarly affected. The parents are living and healthy.

**Examination.**—The patient on examination was mentally alert and of average nutrition and development. He is 51 inches (130 cm.) tall and weighs 54 pounds (24.5 Kg.). He has a waddling gait and runs in a similar fashion, taking short steps. He is able to rise from a supine position without "climbing up himself." There is a moderate lumbar lordosis and bilateral pes planus. There is ptosis of both eyelids, the upper eyelids crossing the cornea just above the center of the pupils, with partial external ophthalmoplegia. The pupils react to light but not in accommodation. The fundi are normal. Bifacial weakness is present, resulting in an ironed out expression. The patient is able to laugh or frown, but weakly. He can wrinkle his forehead, fully protrude his tongue, and whistle. Food does not collect between his teeth and cheeks. Chewing and swallowing are unimpaired, slowly performed without fatigue. Counting

rine alone. At present his condition is stationary, having become so almost a year ago. His physical condition has remained unchanged except for increased muscle strength. Subjectively he feels greatly improved. He does not tire easily and he is able to hold his eyes wide open most of the morning. Any infection or a discontinuation of the medication soon brings about a relapse.

**CASE 2.—History.**—Donald W., aged 15 years, brother of patient 1, has drooping of the eyelids, which began at 6 months following a cold. This was not marked on awakening early in the morning but became quite noticeable later in the day. The patient was not very active and he showed generalized weakness which did not increase in severity. The gait was weak and waddling. No information is available regarding the extra-ocular movements in infancy, but there is evidence that they had been definitely impaired since the patient was 3 years of age. The cry was weak and he was not able to laugh loudly. The facial play of the features was diminished. There was no disturbance of swallowing and he did not tire on eating. He began to speak with a nasal twang at the normal time. There has been a gradual spontaneous improvement since the age of 6 years without the aid of any treatment.

There had been normal fetal movements during gestation and a full term normal labor. There was cyanosis for a short time after birth. The birth weight was 8 pounds (3,629 Gm.).

Fig. 1 (case 1).—The face is expressionless. There is a bilateral lagophthalmos and drooping of the mouth.

Fig. 2 (case 1).—Bilateral facial weakness shown when the patient is smiling.

Fig. 3 (case 2).—A brother of patient 1, showing the bilateral lagophthalmos.

to 75 causes fatigue. The head is held slightly forward. There is no apparent weakness of the muscles of the neck. The thyroid is not enlarged. There is a shallow depression of the sternum and some flaring of the ribs. There is widespread muscular weakness, particularly of the muscles of the back, the flexors of the hips and legs, and muscles of the hands and forearms. There is no muscular atrophy, hypertrophy or fibrillary twitching. The reflexes are normally active; they could not be exhausted readily by repeated stimulation. The myasthenia reaction of Jolly could not be elicited. Roentgen studies of the chest, skull and long bones are negative except that all the long bones are elongated and there is a bilateral coxa valga. The paranasal sinuses show no haziness and the thymus gland is not enlarged. Examination of a section of the triceps muscle demonstrates no pathologic condition.

The blood Kahn test was negative; the basal metabolic rate, —9 per cent and —7 per cent. Spinal fluid was normal. Blood chemistry (Dr. E. L. Wardell) showed: fasting sugar 67 mg., cholesterol 230 mg., total fat 520 mg., creatinine 1.6 mg., non-protein nitrogen 29 mg., total serum protein 6.8 Gm., serum globulin 4.7 Gm., serum albumin 2.1 Gm., chlorides 504 mg., calcium 10.5 mg., phosphorus 4.7 mg., dextrose tolerance test: fasting 77 mg., two hours 111 mg., three hours 92 mg., four hours 78 mg. Urinary creatine and creatinine determinations on a twenty-four hour specimen are given in the accompanying table.

**Course.**—After being placed on aminoacetic acid (glycine) 10 Gm. twice daily and ephedrine sulfate one-eighth to three-fourths grain (0.008 to 0.05 Gm.) three times a day, striking improvement occurred which could not be maintained on ephed-

He held the head erect at 6 months, sat up without support at 8 months and walked at 1 year with a waddling gait. He was breast fed for eleven months, not nursing very vigorously. He received no orange juice or cod liver oil in early infancy. His weight at 1 year of age was 20 pounds (9,072 Gm.).

He had chronic colds from 6 months to 2 years of age, measles at 4 years, chickenpox at 4 years, whooping cough between 2 and 3 years, and otitis media at 1 and 2 years.

**Examination.**—With the exception of partial external ophthalmoplegia (bilateral) and some drooping of the eyelids, which had been lifted surgically several years before admission, the physical examination was negative. The patient is quite active, does not tire readily, has a normal gait and has good muscle power. Speech is normal. There is no facial weakness. Chemical studies on the urine and blood were not done, nor was a biopsy of the muscle taken for examination.

The finding of four cases of myasthenia gravis in one family is extremely interesting and suggests heredity as an important etiologic factor. Three out of five siblings were affected in varying degree, all beginning in early infancy. One other also probably had it, but in a mild form, only presenting a lagophthalmos, and he recovered completely but with a tendency toward recurrences during any acute illness. All are boys. One sister in the family is quite healthy and shows no evidence of weakness. In case 1 the improvement was entirely due to the combined action of the aminoacetic acid and ephedrine. There is still present considerable

intervals of varying length, finally to terminate in an acute form. Menstrual disturbances are common with encroachment on the cervical canal even blocking it, causing hematometra, progressing finally to pyometra. Sounding of the uterine canal will clinch the diagnosis. Bladder symptoms may or may not be present, depending entirely on displacement of the neighboring viscus by the tumor in the process of torsion.

#### DIFFERENTIAL DIAGNOSIS

It is quite significant to note in our survey of the literature that diagnosis prior to operation has seldom been made of axis torsion of the fibromyomatous uterus. The most common diagnoses made preoperatively are ectopic pregnancy, twisted ovarian cyst, appendicitis, adnexal disease and intestinal obstruction.

Elimination of ectopic pregnancy, salpingitis and appendicitis may be aided by the recognition of a tumor, tender, movable and not in the flank, along with absence of chocolate colored blood in the fornices and a clear culdesac. Successful colonic irrigation and a gradual cessation of vomiting will aid in ruling out intestinal obstruction.

#### TREATMENT

Attempts have been made to reduce the axis torsion manually, but this is seldom successful and is frowned on by most authors.

Hysterectomy is usually done in both acute and chronic forms of torsion. Subtotal hysterectomy is preferred because these patients are acutely ill and additional trauma is ill advised. The vessels of the broad ligament will be found to be tremendously hypertrophied and, along with edema and the early gangrenous process, may cause concern with hemorrhage. Very careful ligation of these vessels well beyond the area of any thrombosis is strongly advised.

This accident usually happens from the third to the fourth month of gestation when it occurs in pregnancy. Careful myomectomy here is usually practiced.

#### PROGNOSIS

A very few cases may undergo a spontaneous reduction, but certainly these are exceedingly rare. Piquand reported eight untreated cases and six deaths, an approximate mortality of 75 per cent. He also reported sixty-three cases presenting operative intervention, showing in this group a 10.5 per cent mortality. Other writers' figures further emphasize the gravity of torsion of the uterus, but acute cases given the benefit of surgery recover from symptoms of shock at onset and show a mortality rate practically that from hysterectomy.

#### PATHOLOGY

Generally it may be stated that the pathologic condition found in the fibromyomatous uterus, the adnexa and the surrounding organs is much the same, presenting a picture of circulatory damage, the degree depending on the extent of the torsion.

The average cases show a turn of 180 degrees; however, Wertheim and others report torsions of 300 degrees and more. Venous stasis is usually complete with only partial arterial obliteration, and this causes extensive edema of the uterus and tumor. Lymphatic infiltration along with many cystic spaces, the latter due to separation of the muscular and fibrous elements, will be noted in microscopic section. The uterine cavity contains blood developing into a pyometra. As the process continues one sees development of necrosis.

## DIFFUSE ADENOMATOSIS OF THE COLON

FRED W. RANKIN, M.D.

AND

ALLEN E. GRIMES, M.D.

LEXINGTON, KY.

Diffuse adenomatosis of the colon as a distinct clinical entity has been recognized for many years, but the histopathology revealing its malignant tendency has been a more recent contribution and has done much to alter modern views with regard to treatment. Menzel is credited by Warwick<sup>1</sup> as having first called attention to the disease as such in 1721, and in 1832 Wagner<sup>2</sup> described a condition which is now recognized as polyposis. Rokitsky in 1839 and Lebert in 1861 contributed to the knowledge of the condition. Luschka in the same year reported a case in which a woman, aged 30, was found to have thousands of polypi in the colon. "Colitis polyposa" was used by Virchow<sup>3</sup> in 1863 in describing the lesions.

The tumors are usually multiple and widely distributed, often extending from the anus to the cecum, but having a tendency to appear approximately eight times more frequently in the rectosigmoid and rectum than in any other section of the colon. This is particularly significant in the light of the similar occurrence and ratio of distribution of carcinoma of the colon and immediately suggests a relationship. Pathologic studies of large segments or the complete colon secured by surgical removal have supported this suspicion, and adenomatosis of the colon can no longer be considered an unusual entity of relatively minor importance but one demanding prompt attention and eradication.

Through the years, added bits of information have sealed the verdict for effacement. Cripps, Lockhart-Mummery<sup>4</sup> and Cuthbert Dukes were among those to make noteworthy confirmatory contributions. They noted the occurrence of the disease in several members of the same family and suggested a familial tendency or hereditary factor. Their observation has been repeatedly sustained by various investigators and conforms with our experience. Two of our last three patients reported two members in each family similarly affected with a definite diagnosis established by proctoscopic and roentgenologic examination. This familial tendency or predisposition to adenomatosis of the colon in a way parallels the occurrence of malignancy in families and revives the discussion of polyps as the precursor of many colonic carcinomas.

This question, however, cannot be answered until more definite knowledge is obtained of the etiology of the condition. The following classification, the one most generally accepted at the present time, affords some idea of the views held in regard to the origin of the polyps. Erdmann and Morris<sup>5</sup> make the division of congenital, or adolescent, and acquired polyps. Wesson and Bagen<sup>6</sup> conform to this grouping in speaking of post-inflammatory polyps and true polyps. Lockhart-Mummery elaborated on this classification by considering pathologic and etiologic factors and referred to (1) true

## REPORT OF CASE

**Clinical History.**—I. G., a white boy, aged 8, was taken acutely ill May 2, 1936, with a high fever of 105 F., a slightly sore throat and mild photophobia. His pulse was 130 per minute and respiration 15. The only other positive physical signs were a mild conjunctivitis and a moderately congested throat. For the first three days of his illness the fever was septic in type, ranging from a mild 101 in the mornings to 105 in the evenings. A maculopapular eruption appeared, starting at the back of the neck and the forehead and spreading rapidly downward until it covered the whole body. However, no Koplik spots appeared in the mouth. The clinical diagnosis of measles was made. The white blood cells at this stage numbered 6,200, with a differential count of 55 per cent lymphocytes, 43 per cent polymorphonuclear cells and 2 per cent monocytes.

The fever persisted for three more days; on the seventh day it subsided by crisis. For the following three days the temperature was normal, the rash faded and physically, with the exception of a slight photophobia, the patient appeared to be normal. Because of the acutely severe course of his illness he was advised to remain in bed, but after the second day of normal temperature he was out of bed and running around the room.

The following day, the ninth day from the beginning of his illness, he developed a high fever again (104). The following three days the fever ranged from 103 to 104; the pulse rate was from 120 to 130 per minute; respiration 14 to 16; the white blood cell count was 21,600, with 78 per cent polymorphonuclears, 20 per cent lymphocytes and 2 per cent mononuclears. There was no localization of symptoms and physical examination gave essentially negative results.

On the fourth day of his fever remission he complained of severe pains in his back, abdomen and legs. At about the same time there was rapid development of motor loss in both lower extremities. A little difficulty in voiding the urine was complained of but there was no incontinence at any time.

The neurologic status revealed a conscious, alert youngster, complaining bitterly of pain and resenting any manipulation of his lower extremities, which were extremely hyperesthetic to all tactile or manipulative stimuli.

The pupils reacted promptly to light and during accommodation and the fundi showed no deviations from the normal. Nystagmus was not present. There were no oculomotor palsies. Gross examination of the rest of the cranial nerves revealed normal functioning. The neck was not rigid.

The upper extremities were not involved and the reflexes (biceps, triceps and radial) were active and equal. The lower extremities were completely paralyzed, with abolition of the patellar and ankle reflexes. A bilateral equivocal Babinski sign was present, without any other confirmatory abnormal reflex signs. The sensory examination revealed no sensory loss in any dermatome. Hyperesthesia, however, as already mentioned, was marked in all the dorsal and lumbar dermatomes. The abdominal reflexes (upper and lower) were totally abolished. A lumbar puncture revealed the fluid to be under normal pressure, clear, with a cell count of 4 per cubic millimeter and a faint trace of globulin. Sugar was 0.08 per cent and negative on direct smear for organisms.

**Subsequent Course.**—This state of affairs remained unaltered for three weeks. At the end of this time the patient gradually commenced to regain power in the paralyzed extremities and at the end of another three weeks was able to leave his bed and walk about the room, with assistance. The changes noted in the initial examination were unaltered, but the hyperesthesia was diminishing. He gradually recovered completely and was able to walk and run, unassisted, at about the end of three months following his illness.

A subsequent examination (three months after the paralysis) revealed the following neurologic status: The gait was somewhat spastic and a steppage element was present; the dorsiflexors of the ankle were weak but the dorsiflexors showed good motor power. The musculature of the thighs likewise showed effective strength. The reflexes of the lower extremities manifested a definite reversal, as they had returned com-

pletely and were even exaggerated. The Babinski signs, however, were still equivocally present. The abdominal reflexes also had returned.

The sensory examination was still completely negative and the hyperesthesia had disappeared entirely.

## COMMENT

This case is believed to be worthy of record in view of the fact that it is one of the few recorded cases in the American literature presenting a purely spinal or "myelitic" complication of measles. The usual types encountered are encephalomyelitic, which obviously means invasion of some portion of the encephalon, with its attendant symptomatology and ever present danger of permanently disabling sequelae, which, according to Ford, is as high as 65 per cent. Although our case still shows moderate residual signs, the steady improvement bespeaks a complete neurologic recovery.

A discussion of the mechanism producing the paraplegia, particularly where recovery has occurred, may also be ventured. We believe this to be "toxic-allergic," producing in its wake sufficient swelling of the cord and subsequent constriction of the ganglion cells to interfere with its gross functions. Recovery occurs when the "allergic" reaction subsides. Obviously, if the swelling lasts long enough degenerative changes are the result, which declare themselves clinically by residual neurologic symptoms and signs.

It is barely possible that in measles intoxication the "allergic" skin eruption may have its counterpart in the brain and cord, which might be elicited on careful routine neurologic examination, conducted either at the height of the disease or during convalescence. We believe that a fair number would show "organic" evidence of neural involvement of a transient character.

300 Central Park West.

## REACTION DUE TO INJECTION OF SODIUM MORRHUATE

MAURICE L. DALE, M.D., CHICAGO

A patient of mine experienced a severe general reaction, Oct. 13, 1936, following an injection of sodium morrhuate into a varicose vein. I was unable to find anything in the literature regarding such a reaction until I saw the article by Kenneth M. Lewis in the Oct. 17, 1936, issue of *THE JOURNAL*. It occurred to me to report my case as an additional one of sodium morrhuate reaction, and also because there were certain interesting differences in the history and the reaction.

## REPORT OF CASE

C. W., a man, aged 50, a janitor, July 21, 1936, gave a history of varicose veins of the left leg of fifteen years' duration and ulcer of the ankle for ten years. Two years previously he had been given injections of quinine and urethane twice a week for four months with very little results. He stated that at that time, following each injection, he experienced vertigo, flushing of the face and profuse perspiration, which would last fifteen minutes. The internal saphenous and popliteal group of veins were varicose. There was an ulcer on the anterior aspect of the ankle about 2 inches (5 cm.) in diameter, and the entire ankle showed a brown discoloration with scars of old healed ulcers.

Treatment was started with 1 cc. of 5 per cent sodium morrhuate (Parke, Davis & Co. ampules), one treatment weekly, one vein being injected each time. The dose was increased to 2 cc., 3.5 cc. and finally 5 cc. each time. The response was very good, each injection showing good results. No local or general reaction was experienced at any time.

After the thirteenth injection, October 13, the following reaction was noted: There had been no pause in the treatment during the entire course up to this date. Just as the injection was completed, the patient complained of vertigo and faintness. He quickly grew very pale and the lips and fingers became cyanotic and the pulse imperceptible. The heart tones were weak and slow, irregular both in rate and volume, and about 30 to 40 per minute. The patient quickly became semiconscious. Five minims (0.3 cc.) of epinephrine 1:1,000 was given sub-

One should always bear in mind the fact that polyps of group 1 ordinarily pursue a benign career, that the orderly but more rapidly growing polyps of group 2 tend in time to malignant change, and that formations of the order of group 3 are outrightly precancerous. This makes it absolutely necessary for a complete study of these cases, including proctoscopic examination,

Fig. 3.—Third stage: The insertion of the two halves of the Murphy button into the ileostomy (a) and into the rectum. The ileostomy is contracted down and is too small an opening to admit the insertion of the button without incising the tissue around it down to the peritoneum. The other arm of the button is placed into the rectum and pushed high up toward the end of the rectal loop with a proctoscope and specimen taker. These instruments are withdrawn before the abdomen is opened, and the folds of mucous membrane hold the button fairly well in position.

biopsy when possible, and a roentgenogram of the barium-filled colon that one may not err in assuming that a palpable rectal growth is the only source of the patient's symptoms, when polyps, benign or malignant, may be scattered throughout the bowel at higher levels.

There is usually little difficulty in establishing the diagnosis if the condition is kept in mind and the patient is subjected to a thorough gastro-intestinal investigation. The patients are usually young adults of an average age of 30 years. However, the extreme ages do not escape, for there are reported cases of occurrence of the disease in children of 2½ years and adults past 70 years of age. The chief complaint usually is concerned with some alteration in the bowel habitus, particularly diarrhea. A history of continuous, intermittent or recurring diarrhea existing for months or years may not alone suggest a specific influence, but, if the irregularity occurs in a young adult in whose family other members have been similarly affected, the search should be directed toward adenomatosis. The age incidence and the hereditary or familial factor have been repeatedly emphasized by several observers and in our own series these influences have been frequently noted. The stools may contain blood or mucus, which are in no way characteristic of this particular entity.

A story of recurrent cramps may imply intermittent obstruction. It is a common complaint and is often

due to intussusception. The polyps stimulate the bowel activity to abnormal proportions, which induces various degrees of invagination in the bowel. The infectious processes, such as amebiasis, chronic ulcerative colitis and the dysenteries, can usually be eliminated as causative factors by bacteriologic and cultural studies of the stools.

Weight loss, a secondary anemia, debility and general weakness parallel the intensity of involvement and infection, which at times are so marked as to create grave suspicion of malignancy. Quite often the diagnosis is unfolded to the mind's eye by the simple procedure of placing an examining finger into the rectum, where nodular polyps await and do not defy discovery. This portion of the gastro-intestinal tract, so easily accessible to investigation, is more frequently the site of adenomatosis. The examination should not rest at this point but should be supplemented by sigmoidoscopic search and roentgenologic studies of the barium-filled colon if one would deny oneself the embarrassment of subsequent exposure of unsuspected polyps at higher levels when they may prolapse through a colostomy stoma.

#### TREATMENT

The debilitation resulting from prolonged diarrhea, blood loss and chronic infection, and the pathologic knowledge of the high incidence of malignant change occurring in diffuse adenomatosis of the colon, are the factors that have made radical surgical treatment imperative. To remove a part of the involved bowel, leaving diseased segments, has proved of temporizing benefit at the best. Obviously, then, to be permanently free from the process, treatment had to be designed to remove the whole colon.

Colectomy when first performed was a formidable procedure and, when undertaken in one stage without

Fig. 4.—Anastomosis with button: The end of the button in the ileostomy has been milked down to the position shown for anastomosis. The end in the rectum is brought up to the proper position and held there by the fingers of the left hand. A small opening is made in both the ileum and the rectosigmoid and the button snapped together. The inset (a) shows completed anastomosis with a few interrupted catgut sutures surrounding it.

considerable preparation and rehabilitation, carried a high mortality. A temporary ileostomy was soon devised and its value or necessity was immediately appreciated. By sidetracking the fecal current in this way the associated infection subsided and the rectal discharges of blood and mucus were greatly reduced to

## Special Clinical Article

### TROPHIC FUNCTION OF THE SYMPATHETIC NERVOUS SYSTEM

CLINICAL LECTURE AT KANSAS CITY SESSION

LEON ASHER, M.D.

Professor of Physiology, Berne University  
BERNE, SWITZERLAND

I have the honor to discuss before this distinguished meeting certain research work which has led to establishing the fact that the sympathetic nervous system has trophic functions. This system is often called the vegetative nervous system and that term implies a trophic influence. Modern experimental medicine has denied the existence of trophic nerves mainly on the basis that, when a denervated tissue is protected against outer harmful stimulations, all symptoms of injury are abolished. The contention that the desensitization of, for instance the cornea, was the cause of the ulcerations observed, was correct; but just the protection of the eye on the other side removed the possibility of tracing trophic nervous influence.

The first experiments that my associates and I conducted in the Physiologic Institute at Berne concerned the influence of the sympathetic nerves on voluntary muscles. We were able to show that, when a state of fatigue had appeared, stimulation of the sympathetic nerves leading to the extremity that was forced to work restored those muscles. As this restoration took place without any change in the frequency of the fatiguing stimuli, the conclusion follows that the time of restoration in a state of fatigue has been shortened. This conclusion was verified by various experimental biophysical and biochemical procedures. As sympathetic innervation of the muscle fiber itself was doubtful, an explanation had to be sought which would be independent of specific sympathetic fibers going to the contractile substance. The explanation was not difficult to find, as in our first experiments we were able to show that treatment of the muscle with epinephrine caused the same kind of restoration as did stimulation of the sympathetic nerves.

If, as we presumed, epinephrine was released during muscular contraction, we had to take into consideration the possibility that stimulation of sympathetic nerves brought about heat production in muscles. We were able to demonstrate the calorogenic effect of sympathetic stimulation in muscles in animals. We measured thermoelectrically the temperature in symmetrical muscles, one of which had its normal innervation, while on the other side the sympathetic nerves had been cut. We observed that eventually the side that was still in possession of its sympathetic innervation became warmer. I will not report on the various experiments performed to corroborate the result obtained, but draw attention only to the fact that this new work definitely shows that muscles partake in heat regulation even if they do not contract. Experiments conducted along different lines demonstrated that impulses created in the central nervous system under perfectly normal conditions reach the muscles by way of the sympathetic nerves, so that the latter participate also in muscular activity. In muscles whose only connection with the central nervous system is through sympathetic nerves in the muscles and in these nerves themselves action currents appear

during natural reflexes. If one compares muscles having sympathetic innervation with muscles which have no sympathetic innervation after puncture of the heart center, invariably it is the side having sympathetic innervation that becomes considerably warmer.

These and allied experiments show the very considerable influence which the sympathetic nerves have even on striated muscles; and on glands this influence is still more noticeable. One would still be justified, however, in denying that a trophic nerve effect or influence had been demonstrated in the sense proper of this term. I will proceed, therefore, to discuss experiments that demonstrate a real trophic influence of the sympathetic nerves, by which term I mean that the state of the tissues is regulated by these nerves. I turn to the well known and classic region for the investigation of trophic influence, the cornea. If the cervical sympathetic in the rabbit is extirpated on one side, the eye on this side loses only this innervation, retaining its normal motility and sensibility. To test whether the two corneas react differently, we irradiate the two eyes with exactly the same intensity of quartz rays and for exactly the same length of time. When a certain intensity of the light rays is applied, the two corneas react differently. The eye without sympathetic innervation shows distinct ulcerations (best observed with the aid of the Gullstrand slit lamp), while the normal eye shows no harmful effect. If the intensity of the light is a little stronger, both eyes may show ulcerations; but the difference shows in the length of time required for restoration. At the time the eye with normal innervation becomes perfectly restored, the eye without sympathetic innervation is still in a state of distinct ulceration. These experiments seem to prove conclusively that the sympathetic nerves have a trophic influence. The tissue is evidently less able to withstand the harmful influence because the loss of the sympathetic innervation lowers the trophic power of the cells.

One is also able to demonstrate the trophic influence of the sympathetic in the skin. Intracutaneous injection of histamine will produce blebs in the skin. If one compares the reaction of the normal side with the side without sympathetic innervation and applies graded concentrations of histamine, it will not be difficult to find a concentration which will produce a large bleb on the side without the sympathetic, while on the other side nothing happens. If the concentration of histamine is increased, one may succeed in producing blebs on both sides. But on the side that is normally innervated the blebs will disappear very much sooner. Evidently the skin without sympathetic nerves has become less resistant. A possible explanation is that the more rapid absorption of the fluid in the bleb on the normal side is due to a state of higher permeability. Experiments which we did years ago had already led us to conclude that, by taking away the sympathetic, the permeability was decreased. Comparing the sodium chloride concentration either in the saliva or in tears, we always found the concentration lower on the side without the sympathetic, although there was no difference in the total amount of saliva or tears.

In a third series of experiments we compared the influence of x-ray irradiation on the growth of the bones of young growing rabbits. Every ten days roentgenograms were taken under exactly the same conditions of the bones of both sides. The roentgenograms showed that the development of the bone on the normal side was far greater than it was on the side in which the sympathetic had been excised. The present

It is desirable to close and invaginate the lower end of the remaining rectosigmoid. In adenomatosis it is often difficult to turn in the end of the bowel when the polyps are diffuse, so one may have to be satisfied with closure of the lumen with through and through stitches and safeguard against contamination or separation by suturing fat tags, the omentum or the adnexa in the female over the end of the bowel. At other times it may be necessary to enclose the rectosigmoid stump in iodoform gauze and rubber tissue and drain to the outside.

The patient as a routine receives a blood transfusion following the subtotal colectomy, which protects and provides against the element of shock. The third stage of the operation is advantageously delayed a number of months, during which time the rectal stump may be repeatedly investigated and fulgurated if the polyps have not previously been destroyed. Usually in from three to six months the patient is in readiness for anastomosis of the ileum with the rectosigmoid stump. We do this step by one or two methods, one of which is an aseptic anastomosis over the Rankin<sup>11</sup> clamp, and the other by the Murphy button. The former is quite easily and satisfactorily executed if there is sufficient rectal stump or if the patient is the thin type and the bowel is mobile. If difficulties are encountered, one may always resort to anastomosis with a button. This is probably simpler and more quickly carried out. One part of the button is introduced through the proctoscope and held in place by a long forceps at the desired level in the rectum where the anastomosis is to be made. The other part is placed into the ileum and secured by a purse-string suture, as is done in all anastomoses where the button is used. The separate parts of the button can easily be manipulated in place, the one guided by the operator's hand in the abdomen and the other by manipulation of the proctoscope. When the two buttons are brought alongside each other they can be approximated and locked. The site of anastomosis is reinforced by interrupted sutures.

As a rule, the anastomosis is clean and there is no necessity for drains. The ileostomy is still present and serves as an added safeguard and sidetracks the fecal current from the recent anastomosis until sufficient time has elapsed for its safe and firm healing. Within two weeks the ileostomy, having served its purpose, can easily be closed under local anesthesia. The patient is now returned to a normal anal control and has on the average from two to three semisolid stools a day.

#### CONCLUSIONS

With the addition of two cases completed within the last year, our series now totals thirteen cases, in seven of which, as previously reported, the entire colon and rectum were removed by multiple procedures. In six cases the colon was removed to the rectosigmoid juncture. These operations were undertaken for both adenomatosis and complications arising from diffuse chronic ulcerative colitis. In the earlier cases the more radical total colectomy was done for both lesions. Now it is reserved for chronic ulcerative colitis.

The remarkable disappearance of diffuse rectal polyps following vigorous fulguration encourages us to save the rectal stump and anastomose it with the ileum. However, we condemn any method whereby segments of the colon beyond the rectosigmoid are preserved.

They are a definite menace as a site of recurrent polyps and are beyond the range of proctoscopic investigation.

In this series there was one operative death following the second stage colectomy. Another patient died eighteen months following the completed operation from recurrence of carcinoma, which had developed on polyps and which was demonstrated at exploration.

## MYASTHENIA GRAVIS IN CHILDREN

### ITS FAMILIAL INCIDENCE

HAROLD B. ROTHBART, M.D.

DETROIT

Myasthenia gravis is not infrequently encountered in children, but its familial incidence has never been stressed. My purpose in this report is to present two cases of myasthenia occurring in brothers, in whom the onset was in early infancy, this also being an unusual feature. No attempt is made to review all the cases of myasthenia gravis arising in childhood. It soon becomes apparent to the reviewer that the literature is voluminous and that not a few cases reported in adults had their beginning in early life. There seems to be nothing strikingly different about the disease in children to warrant a detailed discussion of its clinical features.

#### REPORT OF CASES

CASE 1.—*History.*—Marvin W., aged 9, Jewish, admitted to the pediatric service Sept. 12, 1934, complained of generalized weakness, inability to move his eyes normally and drooping eyelids, noted since infancy but more marked during the past year.

Weakness of the eye muscles and abnormal drooping of the eyelids were first observed at 6 weeks of age. Although he developed normally, it was noticed that he could not run or skip a rope like other children and that he was unable to climb. His walk has always been awkward. When he arises in the morning his eyes are wide open but within half an hour the eyelids droop and the eyes become more fixed. He soon tires and this generalized weakness becomes more marked with the progress of the day. Rest periods restore his strength to a certain degree. His facial expression has always been masklike. He is unable to laugh or cry out loud. He has no difficulty in chewing or swallowing. "Asthmatic" attacks are described as having occurred during infancy with noisy breathing, particularly during the night. These were relieved by inhalation of steam. These attacks have not recurred within recent years, but occasionally rattling sounds in the throat are heard. The speech has always been nasal. The patient's general condition has been stationary until about one year ago, when weakness became more marked.

The birth and developmental history are normal. The mother was well during pregnancy. She felt "life" at about the fifth month and the fetal movements were vigorous compared with her other pregnancies. Labor lasted eight hours and was spontaneous. The birth weight was 8½ pounds (3,855 Gm.). The only abnormality observed at birth was the weak cry. Later in infancy the patient did not seem to be very active. He made little effort to kick off the covers even though he was warm. He nursed without difficulty, not tiring during the feeding, he sat up at 6 months, the first tooth erupted at 8 months and he walked at 1 year. When he first began to crawl and walk he was rather awkward and weak. He talked at about the normal time with a nasal twang.

The patient had pneumonia at 6 weeks of age, following which the eyelids were first found to be drooping. Coryza attacks had been frequent during the winter months but not in the summer. He had measles at 8 and a tonsillectomy two years before. There is an occasional nondescript recurring pruritic papular eruption on the body.

From the Department of Pediatrics and Infectious Diseases, University of Michigan Medical School, D. Murray Cowie, M.D., director.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL STATUS OF CATGUT SUTURES

AT THE REQUEST OF THE COUNCIL ON PHARMACY AND CHEMISTRY THE BOARD OF TRUSTEES GRANTED THE COUNCIL AN APPROPRIATION FOR THE PURPOSES OF SPECIAL INVESTIGATION OF COMMERCIAL CATGUT SUTURES.

THE LABORATORY WORK WAS DONE BY MR. JOHN H. BREWER FOR THE COMMITTEE ON CATGUT SUTURES OF THE COUNCIL UNDER THE DIRECT SUPERVISION OF THE CHAIRMAN OF THE COMMITTEE. THE COUNCIL DESIRES TO EXPRESS APPRECIATION TO THE COMMITTEE, AND PARTICULARLY TO THE CHAIRMAN, FOR THE AMOUNT OF EFFORT AND TIME HE DEVOTED TO THIS SUBJECT.

THE COUNCIL HAS ADOPTED THE FOLLOWING REPORT BY MR. JOHN H. BREWER AND AUTHORIZES ITS PUBLICATION.

IN VIEW OF THE FOLLOWING REPORT THE COUNCIL DESIRES TO ISSUE A WARNING AGAINST THE USE OF SO-CALLED CHEMICALLY STERILIZED SUTURES; IN THE OPINION OF THE COUNCIL IT IS BETTER TO USE ONLY HEAT STERILIZED SUTURES UNTIL MORE RELIABLE CHEMICAL PROCESSES HAVE BEEN DEvised.

THE COUNCIL BELIEVES THAT ALL MANUFACTURERS SHOULD PLACE ON THEIR LABELS A DATE OF MANUFACTURE AND THAT PHYSICIANS SHOULD USE THOSE SUTURES WHICH BEAR A DATE MORE RECENT THAN OCTOBER 8, 1936, AT WHICH TIME THE REPORT WAS SUBMITTED TO MANUFACTURERS.

THE NAMES OF THE MANUFACTURERS REFERRED TO IN THE FOLLOWING REPORT WILL BE FURNISHED TO PHYSICIANS WHO MAKE INQUIRY.

PAUL NICHOLAS LEECH, Secretary.

### THE PRESENT STATUS OF THE STERILITY OF CATGUT SUTURES ON THE AMERICAN MARKET

JOHN H. BREWER

#### REPORT OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION

The present survey<sup>1</sup> was undertaken with two objects in view: (1) to study critically the technic which has been heretofore employed in testing the sterility of catgut sutures, to modify this technic as might seem desirable and to describe it in such a manner that it might be of use to manufacturers of sutures and others interested in the control of these products; (2) to determine the status of sterility of sutures now available on the American market and especially of those recently manufactured in comparison with those on the market some years ago.

In reviewing the literature on the sterility of catgut sutures, one finds that before 1929 there was no recognized technic for testing sutures. Each of the manufacturers, if he employed sterility tests, had his own technic. Many of the methods did not employ anaerobic control or, if they did, the mediums were in certain cases incapable of sustaining growth of the more delicate anaerobes such as *Clostridium oedematiens*.

From the Department of Pathology and Bacteriology of the Johns Hopkins University, Baltimore.

1. The following information regarding the firms mentioned in the report is noted:

Firm 2 is no longer in existence. The Council has received information that no sutures have been manufactured by this firm since 1920, when it was taken over by another firm, and that the latter firm discontinued the preparation of tubed catgut in 1925, though through an oversight it was still advertising ligatures in 1936 in a medical journal.

The sutures marketed by firm 8 were actually manufactured for it by another firm and were not being sold by it at the time of this report. The firm merely sent the sutures for academic interest. Therefore, no direct responsibility is attached to firm 8 in this instance.

On October 30 firm 9 wrote that the old ligature material to which this investigation refers has been withdrawn from the market and that its ligatures and sutures are now being manufactured by the Heat Sterilization Method approved by the British Ministry of Health. The firm states that every batch of ligatures prepared is now tested bacteriologically by an outside bacteriologist. The Council commends the firm for its prompt action taken at the difficult period of reorganizing its pharmaceutical department. On November 17, 1936, firm 9 reported as follows: "We attach herewith the original certificates of tests on all Surgical Ligatures manufactured under our new process. All batches have proved Sterile when tested according to the Meleney-Chatfield technique by the independent Bacteriologist who tests all our material."

Bullock, Lampitt and Bushill<sup>2</sup> in 1929 published an exhaustive report on the sterility of surgical catgut. It contains an excellent review of the literature on this subject. They included in this report a technic which was far superior to any that had been suggested previously. They were able to demonstrate that much of the commercial catgut was not sterile. This technic, the result of seven years' research, was immediately made a legal requirement of all catgut manufacturers in England.

In 1931 Meleney and Chatfield<sup>3</sup> published what they considered an effective technic for testing the sterility of catgut. It involved the use of a neutralizing solution containing 1 per cent sodium carbonate and 1 per cent sodium thiosulfate. The authors indicated the necessity of using other neutralizing reagents if antiseptics other than iodine or mercury were used. They used a properly controlled medium which sustained growth of *Clostridium oedematiens* in the fifth dilution. Following the publication of this work, some of the manufacturers awoke to the fact that many of the sutures which they were placing on the market were not sterile. Some of them changed their methods of sterilization, others have retired from the market. At present, all of the manufacturers who have been consulted employ the Meleney and Chatfield technic or modifications of it, the chief differences being in the use of additional controls or in the use of a different neutralizing agent.

Clock<sup>4</sup> has published several papers in which he suggests certain modifications which seem to be of noteworthy value. The 1 per cent sodium carbonate and 1 per cent sodium thiosulfate are sufficient to remove the usual chemical substances, such as mercury, iodine and chloramine, provided they are present only in small quantities. Clock<sup>4</sup> has shown that this neutralizer is not sufficient to remove copper or large quantities of iodine as found in chemically sterilized iodized sutures containing from 12 to 15 per cent of these substances. Large quantities of mercury (3.5 per cent) cannot be removed readily by the 1 per cent neutralizer, but it has been found that a 10 per cent sodium thiosulfate solution is sufficient.

Using the 1 per cent neutralizer, my associates and I have found 15.4 per cent of the sutures from firm 8<sup>5</sup> contaminated. These sutures, made by firm 3 for firm 8, were withdrawn from the market and a quantity was sent to us for experimental purposes. A large number of these were tested by means of 10 per cent sodium thiosulfate and 23.6 per cent were found not sterile, or an increase of 8.2 per cent with the stronger neutralizer. This confirms the observation of Clock<sup>4</sup> that a 1 per cent neutralizer is insufficient to remove large quantities of mercury.

For removing copper, Clock<sup>4</sup> has suggested the use of 5 per cent ammonium chloride and 0.5 per cent ammonium hydroxide. As an added step, it is suggested that an additional tube of distilled water be used to remove any neutralizer which otherwise might be carried over into the culture medium. He also suggests the use of several controls that prevent falsely positive results.

4. Clock, R. O.: The Fallacy of Chemical Sterilization of Surgical Catgut Sutures, Surg., Gynec. & Obst. 56: 149, (Feb.) 1933.  
5. Information obtained from manufacturers of sutures is given in table 1.

weakness with very little change in the facial weakness, ophthalmoplegia or lagophthalmos, although he is able to keep his eyes open fairly wide for several hours in the morning. In the past year little improvement has taken place, but with the cessation of the medication he immediately becomes worse. Infections of the upper respiratory tract have been rather frequent, and these incite a relapse. When first seen in 1930 the "asthmatic" attacks were considered to be of allergic origin. Myasthenia gravis was not thought of at the time. Sensitization studies incriminated a number of foods, which were eliminated from the diet without any improvement. We now know that the asthmatic spells were due to the fatigability of the muscles of respiration. Laboratory studies on our patient have not revealed anything of significance outside of an increased creatinuria. The thymus gland, often found enlarged in such cases, was normal. The long bones presented changes usually identified with pseudohypertrophic muscular dystrophy, which account for the peculiar waddling gait seen in both diseases. It is possible that the coxa valga is the result of weakened muscles and ligamentous supports of the joints. While he was under treatment I observed an increased output of both

*Urinary Creatine and Creatinine: Determination on Twenty-Four Hour Urine Specimen*

creatinine and creatine in the urine, but my last studies show no return to normal figures, a finding frequently observed after the patient has received aminoacetic acid for a relatively long period. The patient was on aminoacetic acid for about a year when the last creatinine and creatine determination on the urine was made.

In case 2 the interesting feature is the spontaneous improvement without the aid of any medication or other kind of therapy. So far this boy has had no relapse, although his recovery cannot be said to be complete in view of the persisting ophthalmoplegia and residual postoperative lagophthalmos. It would be hazardous to state that a relapse may not occur, since recurrences have been observed even after many years of apparent cure, mostly in adults.

Stephenson<sup>1</sup> reported a case of myasthenia gravis in an 8 year old girl whose symptoms began at the age of 9 months following vaccination, with a moderate local and systemic reaction. To his knowledge that was the earliest case in the literature. In the cases reported here the symptoms began even earlier in infancy, at 6 weeks, 3 months and 6 months of age.

#### CONCLUSIONS

1. In one family there were four cases of myasthenia gravis in brothers. In the two cases presented here the

1. Stephenson, J. W.: Myasthenia Gravis in a Child of 8 Years, Boston M. & S. J. 175:169, 1916.

boys are aged 11 and 15 years. One other sibling who died in infancy from pneumonia had definite signs of myasthenia gravis at that time. Another brother develops lagophthalmos during acute infections.

2. Spontaneous remission beginning at 6 years of age occurred in case 2. The other's condition is now stationary, following a period of improvement while on aminoacetic acid and ephedrine.

3. The evidence in these cases suggests that myasthenia gravis is a familial and possibly a hereditary disease.

## Clinical Notes, Suggestions and New Instruments

### PARAPLEGIA FOLLOWING MEASLES

CHARLES ROSENHECK, M.D., AND HARRY BAROWSKY, M.D., NEW YORK

The development of nervous complications and sequelae in acute infections in childhood is always of interest and concern to the neurologist and the pediatrician. On account of the inherent instability of the central nervous system in the young, its vulnerability and reaction to toxic substances is very much enhanced. This fact is a common observation clinically and one notes all forms of abnormal neural manifestations in the wake of toxic invasion of whatever type.

The exanthems in particular contribute a goodly share of these neural disturbances, and measles "encephalitis" is pretty well known and recognized by the profession. Other forms and combinations, affecting single or multiple parts of the central nervous system, each registering in its own particular manner interference with function, are seen from time to time, although the incidence is very low.

Thus, according to Rolleston,<sup>1</sup> "encephalitis" occurs in measles more commonly than after any of the other diseases of children, although the incidence is very low even in measles. Boenheim<sup>2</sup> states that among 5,940 cases of measles treated in the various hospitals in Berlin between 1905 and 1925 there were nervous complications on 0.4 per cent, including eight cases of "serous meningitis," six cases of "encephalitis" and eleven cases of unexplained convulsions.

In Ford's<sup>3</sup> comprehensive article, every neurologic complication of measles, with case reports indicative of each group, is tabulated. An analysis of these tables reveals a preponderant number of cases of diffuse cerebrospinal involvement with a relatively small number of pure spinal forms. The latter have been responsible for the paraplegic or "myelitic" syndrome, similar to our own case.

The extreme rarity of this neurologic complication of measles is evidenced by the fact that a thorough search of the American literature yielded but one case, that reported by Miller and Ross.<sup>4</sup> The two cases reported by Bassette<sup>5</sup> and included by Ford in his tabulation are not pure "spinal" forms but indicate brain-stem involvement as well. The few cases reported are scattered in the foreign literature, principally the French and the Italian. It may be of interest to note that the first recorded case of paraplegia following measles occurred in a woman, aged 23, and was reported by James Lucas<sup>6</sup> in 1790.

used as the tubing fluids. The temperatures for heat sterilization varied from 300 to 320 F. (149 to 160 C.). This information is presented in table 1.

Sutures examined have been obtained from the manufacturers, bought in the open market or from hospital supply rooms. A few of the sutures examined are known to have been in stock for more than ten years. These are of special interest in that some of them were found nonsterile, although they were stored in heavily laden mercuric tubing fluid. Not all the brands of sutures to be found on the American market were examined, but all of those recently advertised in the leading medical and surgical journals were given thorough study.

The general procedure for this survey has been, first, to test all the sutures according to the technic of Meleney and Chatfield; then to test the same type of sutures using the additional controls and neutralizing agents suggested by Clock, except in the instance of sutures in which copper was used.

All transfers were made in a "dust-proof" chamber. The bacterial content of the air within the chamber was checked by exposing blood agar plates, throughout the period of transfer, directly in front of the operators in the vicinity in which the transfers were being made. These exposed blood agar plates were incubated aerobically and anaerobically. The anaerobic plates were incubated in a Brown<sup>6</sup> jar. An unexposed plate was incubated along with each exposed plate to serve as a control. The plates had from 0 to 7 colonies after forty eight hours' incubation. The average was 1.53 colonies per plate. This would indicate that the air in the room was relatively free from bacteria. Since the actual time of transfer for each suture required less than a second, and the surface exposed was much less than the surface of the blood agar plate, the chance of an air contaminant entering was slight. This is borne out by the fact that although more than 3,100 transfers were made only two sutures showed growth of the same type of organism, which appeared on the blood agar plates exposed during the time when the sutures were being handled. Throughout the survey, 76 per cent of the organisms that grew on the blood agar plates were cocci and in only two instances were cocci recovered from the sutures.

The culture medium used for the sutures was similar to that used by Meleney and Chatfield and by Clock. The medium consists of meat infusion broth containing 1 per cent peptone, 0.5 per cent sodium chloride, 1 per cent dextrose and 2 per cent gelatin. The final reaction is  $pH$  7.4. To the anaerobic medium 0.1 per cent azolitmin is added. It is the original formula of Novy except that, instead of 1 per cent of litmus, 0.1 per cent of azolitmin was used for the anaerobic medium. The medium is tubed in 40 cc. amounts in test tubes 25 by 210 mm. and is sterilized in the autoclave.

Following is a detailed account of the technic used, which is based on that of Meleney and Chatfield with modifications suggested by Clock or found advisable during this survey. For purposes of comparison, the various procedures are numbered to correspond with those of Meleney and Chatfield.<sup>7</sup>

1. Two operators wearing sterile hoods and gowns make transfers in a dust-free room, which is washed down with a disinfectant (saponated solution of cresol) each time a set of transfers is to be made and allowed to remain closed fifteen minutes before use.

2. The sutures to be tested are registered and the following information recorded:

Firm Name:	No.:
Purchased or received from:	
Type of Suture:	
Company Design:	
Size:	Lot or Lab. No.:
Dist. water:	Boilable or Nonboilable
Results:	Mediums:
Anaerobic	Culture No.:
Aerobic	Culture No.:
Date started:	
Remarks:	

A file mark is made about one-half inch above the tubing fluid. The tubes are numbered with a diamond point and set in a small test tube rack. In the dust-free room just before the transfer is to be made, the tube is flamed at the filed line so that it may be broken without risk of contaminating the suture. When sutures in envelop containers are being tested, one margin of the envelop is flamed and cut with previously flamed scissors (same technic as for sterilizing transfer forceps).

3. The tube is cracked at the filed line by holding a red-hot curved wire against it. A pair of long, previously sterilized, forceps are dipped in alcohol and flamed. The upper part of the cracked tube is removed by grasping it with the back part of the forceps; then the entire suture is seized with the points of the forceps and dropped into a large cotton plugged test tube containing 40 cc. of sterile distilled water.

4. The tube is incubated for twenty-four hours at 37 C.

5. The catgut is then transferred to a test tube containing 40 cc. of sterile 1 per cent sodium thiosulfate and 1 per cent sodium carbonate and again incubated for twenty-four hours.

6. Shortly before use, the culture medium for the anaerobic tubes is allowed to remain in flowing steam for fifteen minutes or more, so that the air is driven out and the litmus is decolorized. The aerobic tubes must be taken from the refrigerator and placed in warm (37 C.) water so that the medium will be liquid.

7. The petrolatum (melting point, 48 C.) sealing material kept in a specially designed closed copper funnel fitted with a hooded stopcock is sterilized in the hot air oven for two hours at 165 C. and, if it becomes too cold before use, it may be placed in the flowing steam along with the anaerobic mediums. We have obtained good growth in our controls using a petrolatum of this melting point and find no advantage in using a mixture of petrolatum and paraffin such as was used by Novy, by Meleney and Chatfield and by Clock.

8. The catgut is then transferred to the tube of medium cooled to 37 C., and the tubes to be incubated anaerobically are sealed by flowing on a layer of sterile petrolatum 2 or 3 cm. thick. The sealed tubes are immediately placed in a cool water bath to solidify the seal. In order that a large quantity of oxygen may not reenter the heated tubes before the petrolatum is added and solidified, only fourteen sutures are tested in a group. It consumes about fifteen minutes from the time the tubes come from the autoclave or steam bath until they are sealed.

9. The tubes are incubated at 37 C. for fifteen days and are examined daily for growth.

10. The medium is tested for sterility by incubating two of every sixteen tubes for the full time of the test, one aerobic tube and one anaerobic tube. The distilled water and the neutralizing solutions are also tested for sterility by culturing 10 cc. amounts, aerobically and anaerobically. These have always been found sterile. The growth-producing properties of each lot of medium are controlled by a series of six tubes planted with decimal dilutions of an active culture of *Clostridium oedematiens*. If growth does not appear in all tubes including the fifth dilution, which is 0.00001 cc. of the original culture, the medium is considered inferior, and not used. It is our opinion that *Clostridium oedematiens* or some one of the more strict anaerobes should be used as the control organism rather than *Clostridium sporogenes* as used by Clock. Several of the suture manufacturers use other organisms which are not strict anaerobes. Meleney and Chatfield<sup>8</sup> suggest that, if a pathogenic species cannot be used, *Clostridium sporogenes* should be substituted for *Clostridium oedematiens*. In sending a subculture of the original Novy strain of *Clostridium novyi* (*Clostridium oedematiens*) isolated in 1893, Dr. M. H. Soule:

6. Brown, J. H.: An Improved Anaerobe Jar, J. Exper. Med. 33: 677 (June) 1921; 35: 467 (April) 1922.

7. Soule, Malcolm: Personal communication to the author from Hygienic Laboratory, University of Michigan.

cutaneously. The heart tones fell to 20 per minute and became almost inaudible for about forty-five seconds, then slowly began to pick up and in about three minutes were normal. The color became good. About five minutes later the entire chain of symptoms recurred. This time I tried giving one-half ounce (15 cc.) of whisky by mouth. The symptoms continued to progress and in about a minute the heart tones were inaudible and the patient entirely comatose. Ten minims (0.65 cc.) of epinephrine was given intravenously. The response was rapid, the heart tones becoming strong and rapidly increasing in rate, reaching 110 in about two minutes. The patient looked and felt normal in fifteen minutes. He was watched for two hours and showed no abnormal signs. One week later he reported that he had had no further symptoms.

## COMMENT

This case differs from Dr. Lewis's in that:

1. There was no period of cessation of treatment during which the patient could have become sensitized.

2. The chief symptom was bradycardia, resembling heart block instead of tachycardia.

3. There was no urticarial rash, bronchial spasm, intestinal spasm or any other of the phenomena one usually associates with anaphylaxis.

I have previously had a patient who experienced transient vertigo, lasting about fifteen seconds, following each injection of sodium morrhuate. During these attacks she would become somewhat pale, the lips would be slightly cyanotic, and the pulse would become slower and skip a few beats. The reactions did not alarm the patient, but when they occurred regularly after each injection I discontinued the treatment.

It is probable that this is not an anaphylactic reaction due to some liver protein remaining in the solution, as suggested by Dr. Lewis, but rather a specific reaction due to an idiosyncrasy to the sodium morrhuate.

## A METHOD OF PATCH TESTING WITH PLANT OIL

BEDFORD SHELMIRE, M.D., AND J. HARVEY BLACK, M.D., DALLAS, TEXAS

Prior to four years ago our patch testing of individuals in suspected cases of contact eczema from plants was a time consuming procedure. Because of the seasonal occurrence and the predilection of the eruption for the exposed areas, such as the face, neck, hands, forearms and legs, a tentative diagnosis of contact dermatitis of plant origin was usually readily made. As most of our patients came from rural communities and often from a considerable distance, patch testing to determine the offending agent was often necessary on the patient's initial visit. This required frequent excursions into the country to collect plants which the affected individual was most likely to encounter. Weeds common to the patient's particular locality often grew sparsely or only in certain parts of our territory. This frequently necessitated rather wide excursions for the collection of a few common specimens.

After the plants were collected the application of the patch test, with the necessary washing of the hands after each test, required more time than could conveniently be devoted to one patient. In one instance the collection of thirty weeds and the application of the tests required over three hours. In another instance the application of seventy-two specimens of flowers and shrubs, furnished by the patient, required almost two hours. With patch testing material available, even when one works rapidly, it requires considerable time to apply the substance, cover with some impermeable material, securely anchor it to the skin, and carefully wash the hands.

About four years ago a large number of the more common Texas weeds, flowers, shrubs and leaves of the low hanging trees were collected and placed in bags. After complete drying these were ground and placed in wide-mouth stoppered bottles for routine testing. This eliminated almost daily excursions into the fields and seemed temporarily to solve our problem. Some of these powdered specimens are now over four years old and seem to have lost none of their original antigenic properties.

As the number of collected plants increased this method also proved time consuming, since each powdered plant had to

be applied separately, the anchoring material adjusted and the hands thoroughly washed after each test. Our testing time had been about halved since collecting the material was not now necessary, yet the procedure was still a tedious one.

Twenty-six months ago it was decided that some new method was needed to shorten the time required for such testing.

Plants were collected, allowed to dry thoroughly, broken into small particles and placed in pint Mason fruit jars. The jars were completely filled with the dried material and commercial ether was added to cover the plants to be extracted and the jar was then tightly sealed. After standing for twenty-four hours the ether extract was poured into an open vessel and allowed to evaporate. No effort was made to remove the chlorophyll or to purify the oil. The oily residue was then placed in small vials and was ready to use. As most of the weeds, flowers and leaves of trees yielded an abundance of oil, the procedure was found to be a very inexpensive one. A second extraction was necessary from certain plants to secure a desired quantity of oil. Sufficient oil to make approximately fifty tests has cost about twenty-five cents.

As these oils are neither true fats nor simple glycerids of fatty acids, it was presumed that, if they were kept dry, bacteria would not grow in them and that if rancidity developed it would be due to enzymatic activity or oxidation. For this reason and to prevent possible false reactions, no preservative was added to our oils. We now have on hand forty oils which have been kept at room temperature for more than two years. These have been opened repeatedly for patch testing. Rancidity apparently has not developed in any of them. Patch testing with these oils shows that they have retained their original eczematogenous properties for sensitive individuals and have not become antigenic for previously nonsensitive persons.

Our oils are kept in small vials with rubber bulb stoppers to which are attached capillary tubes. As the usual sites of contact dermatitis from plants are on the exposed areas (face, neck, hands, forearms and legs) the back is the area usually chosen for application of the tests. In applying an oil the capillary tube, which extends into the oil, is filled by squeezing and releasing the bulb stopper. A drop of oil is then placed on the skin and spread by the tip of the capillary tube over an area approximately 1 cm. in diameter. The tests are applied vertically in rows of ten; no covering is placed on the sites. After a few minutes allowed for drying, the upper test in each row is numbered with 10 per cent silver nitrate. Patients are advised not to bathe for twenty-four hours. About five minutes is required to apply and adequately number forty tests, the number of oils we use as a routine at the present time.

Besides the convenience of this method of patch testing with plant oils, the procedure encourages routine testing with a larger number of plants. This has proved that many plants heretofore considered innocuous have been excitants in distressing local or widespread eruptions. Through routine patch testing it has been proved that in this vicinity *Parthenium hysterophorus* causes a greater number of contact eruptions than any other plant except ivy (*Rhus radicans*). Our bitter-weed, or dog-fennel (*Anthemis catula*), is a frequent excitant of contact dermatitis. In addition to the well known eczematogenous short and giant ragweed and bur-weed marsh elder, such plants as sun flower, Shasta daisy, Amoor river privet, hack-berry, mesquite trees, field corn, cotton, broom-weed, milo-maze, sorghum, trumpet vine, fig, mustard greens and cockle-bur have been proved the cause of annoying contact dermatitis. Positive patch tests have frequently led us first to suspect many of these excitants.

**What Gifts Should a Student Bring?**—In plain words, What gifts of heart and mind ought a student to bring to the service of his hospital? He ought to bring those gifts which come of a good disposition, a good home and a good public school. He should have reverence, and a fair liking for work, and a certain simplicity or directness of thought; and should know Latin, and a manageable quantity of general facts; and should be resolute, in company, and even against company, to say the right thing and take the right side. One more gift he should have, which time alone can give, a sufficient age.—Paget, Stephen: *Confessio Medici*, New York, Macmillan Company, 1931.

be remembered that these transfers were made in filtered air, under rigid asepsis.

One thousand and twenty sutures have been tested for sterility and a summary of the results is given in tables 2 and 3.

Firms 2, 3, 4, 5 and 8 no longer manufacture sutures, but some of their products may still be found on the market.

It may be of interest to note that firm 3 was successor to firm 4 and that the sutures from firm 8 were manufactured by firm 3.

Sutures of firms 10, 11, 13 and 14 manufactured before the advent of the Meleney and Chatfield technic (1933) were not available for this study. No comparison therefore can be made of the older and newer sutures manufactured by these companies.

Twenty-six of the thirty-two organisms isolated were gram-positive aerobic spore formers, most of them being members of the cereus or subtilis groups, and several were unidentified.

Two of the remaining six organisms were gram-positive cocci and were the same types as were picked up on the blood agar control plates at the times these transfers were made; therefore they are not to be considered as derived from nonsterile sutures.

Of the remaining four organisms, two died before identification was completed and the other two were nonidentifiable anaerobes which were found to be non-pathogenic for guinea-pigs.

The important consideration regarding the work of Meleney and Chatfield is not that they found 12.5 per cent of the sutures which they tested nonsterile but the fact that seven firms of the seventeen represented had placed nonsterile products on the market. Several of these manufacturers were not making sutures at the time the survey was made but their products were still on the market.

Clock has purchased, on the open market for the past five years, twelve American brands of catgut. He has found seven brands to be uniformly sterile and five brands nonsterile, except that for one year (1933) he found eight brands sterile and four nonsterile.

Of the fourteen brands tested in the present survey, sutures of six firms were found not sterile. Four of the fourteen firms no longer manufacture sutures.

TABLE 3.—Results from Recently Manufactured Sutures

Firm	Method of Sterilization	Number Tested	Nonsterile
1.....	Heat	128	0
6.....	Heat	114	0
7.....	Heat	134	0
9*.....	Heat or chemical	142	5

11.....	Heat	72	0
13.....	Heat	94	0
14.....	Heat	24	0
Totals.....		800	5

\* See statement concerning firm 9 in footnote 1.

When recent products of the other firms were examined, only one of the firms was found to have nonsterile sutures among those examined. There may be still on the market some old nonsterile sutures from some of these manufacturers, but sutures made by these companies since the advent of the Meleney and Chatfield technic have been found sterile, as is shown in the case of firm 6. Failure to distinguish between sutures recently manufactured and those in stock for some time may account for Clock's results in continuing to find

products of five companies nonsterile. In the case of some of the companies, the date of manufacture is printed on the box along with the sterility seal, while with other brands it is practically impossible to learn the date of manufacture.

Since most of the organisms isolated from the sutures were aerobic spore formers, one is likely to suspect that these organisms may have been introduced as contaminations during transfer for the sterility test and that

TABLE 4.—Comparison of Results Obtained by Various Investigators

	Number of Sutures Tested	Number of Nonsterile Sutures	Number of Firms Represented	Number of Firms with Nonsterile Sutures

Present survey .....	1,020	30 (3.0%)	14*	6 (43%)
Sutures known to have been manufactured since the firms have been using the Meleney and Chatfield or a similar technic, present survey..				
	800	5 (0.6%)‡	6§	1 (12.5%)

\* Several of the firms represented were no longer manufacturing sutures at the time these surveys were made but their products were available on the market.

† It is not stated whether these firms were continuing to manufacture sutures, but Clock does state that these firms had sutures on the open market at the time his survey was made. He does not mention the date of manufacture.

‡ These five nonsterile sutures were from 142 sutures tested for the same firm.

§ These are the major suture manufacturers whose advertisements appear in current issues of the leading American surgical and medical journals.

the sutures may have been sterile before being opened. The following facts indicate that the results were not due to contamination at the time of testing:

At the same time that the nonsterile sutures from firm 8 were tested, sutures from firms 1, 5 and 7 were also tested and these sutures were found sterile throughout the survey. The four sutures from firm 6 which showed growth were all from the same box of sutures, which were known to have been manufactured previously to the time this firm started using the Meleney and Chatfield technic. These nonsterile sutures were all found at different times while other sutures, which remained sterile throughout the survey, were being tested.

The sutures from firm 2, of which 33 per cent were found to be nonsterile, were all manufactured before rigid tests for sterility were employed.

Sutures from firms 3, 4 and 8, which were manufactured in the same plant, showed contaminations of 3, 18 and 23 per cent respectively. All the nonsterile sutures from firms 3 and 4 were found at different times, when sutures from other firms tested at the same time remained sterile. The nonsterile sutures of firm 4 were all from the same carton.

Four of the five nonsterile sutures of firm 9 were received in the same shipment and their lot numbers were very close, although the date of manufacture was not given.

Interesting conclusions may be drawn from the data in table 4.

When considering all the sutures tested in the three surveys, one instantly notes that practically the same proportion of manufacturers were found to have nonsterile products. If only sutures of recent manufacture are considered, the percentage of firms placing nonsterile products on the market drops from 43 to 12.5, indicating that fewer nonsterile sutures are now being

of the sympathetic nerves had aided bone tissue to react more strongly to the irradiation.

We used Ellinger and Hirt's method of observing living tissues microscopically after the injection of fluorescent dyes. On the side without the sympathetics, not only the blood vessels but also the lymphatics were distended and the intensity of the color was much less. The latter fact is again a symptom of decreased permeability on the side without the sympathetic. The distention of the lymphatics is an expression of deterioration of the trophic state of the cells.

From a physiologic point of view, one would expect that functional changes would go hand in hand with changes in the trophic state of tissues. To investigate this question, we tested the excitability of parts of the nervous system in normal animals and after sympathectomy. In this type of experiment we used physical stimuli. We examined experimentally the influence of various intensities of light on the eye and measured the response by recording the action currents of the visual area in the brain. Here one cannot compare the two sides but must make observations before and after sympathectomy. Our results were definite. After sympathectomy for a given intensity of light the response of the visual area in terms of action currents was less. Far more striking was the earlier appearance of fatigue when the illumination lasted some minutes. Another suitable reaction is the reflex movement of guinea-pigs on acoustic stimulation by high pitched sounds. After sympathectomy a higher intensity is necessary to produce the reflex. Both series of experiments show that the sensitivity of sensory centers is regulated by the sympathetic nervous system.

I believe that with these facts we are warranted in attributing to the sympathetic nervous system a regulatory influence on the trophic state of tissues. However important the recognition of trophic innervation may be to physiology, it is still more important to pathology.

101 Effingerstrasse.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

### FISCHERQUARTZ ULTRAVIOLET LAMPS, NOS. 12 AND 15, ACCEPTABLE

Manufacturer: The Fischer Corporation, Glendale, Calif.

The Fischerquartz Ultraviolet Lamps, Nos. 12 (Table Model) and 15 (Floor Model) have been submitted to the Council for consideration. According to the firm, these lamps are similar in construction to the Fischerquartz Ultraviolet Lamp, Model No. 77, which was accepted by the Council.<sup>1</sup>

Evidence was submitted by the firm, and substantiated by the Council's investigator, indicating that the burner of these two lamps was similar in construction to that of Model No. 77. Therefore it seems relevant to include in this report the radiation characteristics on Model No. 77 as previously published.

At a distance of 2 feet from the front edge of the quartz tube (the "burner") the energy flux of wavelengths shorter than and including 3,130 angstroms was 1,050 ergs per square centimeter per second ( $105 \mu\text{W}/\text{cm}^2$ ). Of this amount about 97 per cent is contained in the strong resonance emission line of mercury vapor at 2,537 angstroms. Assuming an erythemogenic efficiency of 50 to 55 per cent at the 2,937 angstrom line, the calculated time of exposure to produce a threshold (M. P. E.) erythema is about seven minutes.

Exposure of small areas (2 by 6 mm.) of the unpigmented inside upper arm at a distance of 2 feet from the lamp, for

intervals of from five to twenty minutes, produced a decided reddening of the skin in seven minutes. The twenty-minute exposure was overexposed and sore to touch.

Since the erythema test was made on a skin of average pigmentation, it is evident that a blond-skinned person should not be exposed longer than about five minutes, at a distance of 2 feet from the burner of this type of lamp.

The intensity of the ultraviolet radiation is above the minimum for acceptance adopted by the Council. With the understanding that this lamp is to be used for irradiation of the body (not applicable for cavity irradiation) for therapeutic purposes, under the guidance of a qualified physician, the lamp was recommended for acceptance by the Council's clinical investigator.

The Council wishes to make it clear that such a lamp has nothing in common with "sunlamps," and that

it is no more applicable than other small therapeutic lamps for home use under the direction of a physician.

In view of the acceptable report on these two units, the Council on Physical Therapy voted to include the Fischerquartz Ultraviolet Lamps, Nos. 12 and 15, in its list of accepted devices.

Fischerquartz Ultraviolet Lamps, Models 12 and 15.

### FISCHERQUARTZ PORTABLE "COLD" MERCURY ARC LAMPS, NOS. 17, 78, 87 AND 95, ACCEPTABLE

Manufacturer: The Fischer Corporation, Glendale, Calif.

The firm describes these lamps as follows:

**Model No. 17 Portable Fischerquartz Lamp.**—Supplies ultraviolet radiation for general body treatments. The transformer, switch and attached cords are installed permanently in the case and sufficient space is provided for storing the burner within the case when not in use. The lamp bonnet is hemispherical, with a flat aluminum reflector across the front. The quartz tubing is attached to this reflector, and all connections are made within the bonnet, where they cannot come in contact with patient or operator. Same as Models No. 78, 87 and 95, only it is housed in carrying case 15 by 16 by  $5\frac{1}{4}$  inches. The shipping weight is  $18\frac{1}{2}$  pounds.

**Model No. 78 Portable Fischerquartz Lamp.**—Supplies ultraviolet radiation for general body treatments only. Body grid only. It cannot be converted into a No. 95 Combination Lamp. Complete shipping weight, 25 pounds. Size 8 by 15 by 22 inches.

**Model No. 87 Portable Fischerquartz Lamp.**—Supplies ultraviolet radiation for general body treatments only. It can be converted into a No. 95 Combination Lamp at any time by adding the official burner. Complete shipping weight 27 pounds. Size 8 by 15 by 22 inches.

**Model No. 95 Portable Fischerquartz Lamp.**—Supplies ultraviolet radiation for both official and general body treatments. Shipping weight 29 pounds. Size 8 by 15 by 22 inches.

These lamps have burners, reflectors, transformers, cords and switches of the same size and type as supplied in the previously accepted nonportable lamps, bearing the same catalogue numbers.<sup>1</sup>

Therapeutically, these lamps generate 150 F. U. (Finsen units) at 12 inches and will produce a perceptible erythema on untanned skin in 0.5 minute at 12 inches, 1.4 minutes at 20 inches and 3.1 minutes at 30 inches. The output of these lamps was checked with the ultraviolet photometer and found to be satisfactory. The power consumption is 63 watts.

The Council on Physical Therapy voted to include the Fischerquartz Ultraviolet Lamps, Portable Models 17, 78, 87 and 95, in its list of accepted devices.

Fischerquartz Portable "Cold" Mercury Arc Lamp No. 95.

1. Fischerquartz Ultraviolet Lamp, Model No. 77. Acceptable, J. A. M. A. 106:1806 (May 23) 1936.

1. Fischerquartz "Cold" Ultraviolet Lamps Acceptable, J. A. M. A. 103:1620 (Nov 24) 1934

## THE EFFICIENCY OF SERODIAGNOSTIC TESTS FOR SYPHILIS

Two years ago an evaluation was made of serodiagnostic tests for syphilis and modifications of such tests as had been originally described by serologists in the United States.<sup>1</sup> On the basis of specificity and sensitivity, the original tests as performed by the workers who described them were found to be efficient as laboratory procedures in the detection of syphilis. In the first study consideration was not given to the adaptability of the various tests as they might be performed by workers in state and local laboratories.

Recently the second report of the Committee on Evaluation of Serodiagnostic Tests for Syphilis has been published.<sup>2</sup> In it is described a project in which the directors of thirty state, municipal and private laboratories undertook fifty-one performances of nineteen separate serodiagnostic methods. Eight of these methods were those described by serologists who had participated in the first study to evaluate original tests. For each of these eight methods a control examination was performed by the serologist who originally described the test. The Kolmer complement fixation test was the one most frequently performed, being chosen by fourteen of the thirty participating laboratories. The Kahn standard flocculation test was selected by twelve laboratories, the Kline diagnostic flocculation test by seven, the Kahn presumptive and the Kline exclusion flocculation tests by two laboratories each and the Eagle, the Hinton and the Johns flocculation tests by one laboratory each. The eleven remaining performances comprised a heterogeneous group of serologic tests which had not been given consideration in the first study and with the exception of the Eagle complement fixation and the Micro-Hinton flocculation tests control examinations were not made

for this group. The specimens submitted in the second project are not, of course, entirely comparable. Because of the difficulties encountered in collecting comparable samples for all participants, it was found necessary to establish four separate groups of serologists. The serologists in each group received comparable samples from the same series of donors. Since different donors were used in each series, comparison cannot be drawn between the percentages of sensitivity and specificity for the methods that were evaluated.

Careful study of the tables which are presented in the second report shows that in some of the state and local laboratories the performance of serologic tests does not compare favorably with the results achieved in the laboratories of the originators of the methods. In some of the former laboratories, false positive reports were made in from 3 to 9 per cent of specimens from nonsyphilitic persons. In others the sensitivity of the tests dropped to an alarmingly low percentage.

The results achieved in other state and local laboratories, however, are quite comparable to those obtained with the control performances. Special note should be made of the apparent efficiency of a micromodification of the Hinton test. This test attained a sensitivity of almost 92 per cent and a specificity of 100 per cent as compared with a sensitivity of almost 89 per cent and a specificity of 100 per cent as attained by Hinton running the control. This micromodification of the Hinton test should be given careful study in the future because of the great practical value of an efficient serologic test for syphilis requiring only a small amount of blood serum for its performance.

Also to be noted is the performance of one laboratory in the Kolmer complement fixation series. This laboratory attained a sensitivity of 71.4 per cent and a specificity of 100 per cent, as compared with the 59 per cent sensitivity and the 100 per cent specificity rating of the control performance by Kolmer.

One laboratory in the Kahn series attained good results with a rating of 78.5 per cent for sensitivity and 100 per cent for specificity in contrast with 75.7 per cent sensitivity and 100 per cent specificity for the control performance by Kahn. The examples which are cited indicate the fact that a serologic test for syphilis can, under conditions of routine performance, be perfect with regard to specificity and at the same time have a reasonably high degree of sensitivity. There is no question but that specificity is the most important requirement of a serologic test for syphilis because of the frequency with which such tests are depended on by the physician in private practice in clinching the diagnosis of syphilis, particularly in the latent stage.

The performance of other laboratories participating in this project indicates the usual tendency of serologic tests to become less sensitive when specificity is increased or less specific when sensitivity is increased. Much of this undesirable trend away from specificity and sensitivity is due to individual peculiarities of tech-

2. Parran, Thomas; Hazen, H. H.; Sanford, A. H.; Seneear, F. E.; Simpson, W. M., and Vonderlehr, R. A.: Efficiency of State and Local Laboratories in the Performance of Serodiagnostic Tests for Syphilis, *Ven. Dis. Inform.* 18:4 (Jan.) 1937.

Before attempting this survey, it was necessary to determine the chemical nature of the various sutures. It was important to know the types of tubing fluid and the method of sterilization used by the various manufacturers.

Firms 1, 6, 7, 9, 10, 11, 12 and 14 were asked to furnish the following information:

1. The detailed method of sterilization employed to render the sutures sterile.
2. A quantitative statement of the tubing fluid in which the sutures are immersed.
3. If chemical sterilization is employed, a statement of the qualitative determinations of copper, mercury or iodine that are

employed; also the quantitative upper and lower limits of the amount of mercury with which the suture is impregnated or which may adhere to the suture after its removal from the tubing fluid. If the suture is not suspended in fluid and is impregnated, a statement of the amount in the suture is desired.

The information needed was in most instances obtained in this manner, and it was found that all the companies employ heat sterilization except in one instance. One manufacturer (firm 9) chemically "sterilizes" iodized sutures. The tubing fluid in nearly all cases contained potassium mercuric iodide 1:1,000. Xylene, chloroform, toluene and alcohols in varying proportions were

TABLE 1.—Information Obtained from Manufacturers of Sutures

Firm	Question 1 Method of Sterilization	Question 2 Tubing Fluid Used	Question 3 Regarding Chemical Sterilization
1	Bollable sutures are coiled, placed in glass tubes and dehydrated. The tubes are then filled with the tubing fluid and hermetically sealed by fusion of the glass. The sealed tubes are submerged in a bath of cumol in an autoclave and the heat applied in progressive steps until the maximum temperature is maintained for the requisite period (time and temperature not stated)  Nonbollable sutures are coiled, placed in tubes, dehydrated, covered with cumol, placed in the autoclave and the heat applied as for the bollable type. After sterilization the cumol is removed from the tubes with aseptic technic, the tubing fluid is added and the tubes sealed in the flame	Bollable sutures: toluene or xylene  Nonbollable sutures: ethyl alcohol, 100 gallons; potassium iodide, 80 Gm., and red mercuric iodide, 109 Gm.	Chemical sterilization is not employed in the preparation of any (firm 1) suture, intensive heat sterilization being used exclusively
6	Nonbollable sutures are coiled, placed in tubes and labels enclosed. The tubes are then immersed in a cold bath of hydrocarbon oil and heated gradually to 310 F. (154 C.), held at that temperature not less than one hour and allowed to cool. When cold, the tubes are removed from the bath, the hydrocarbon oil drained, the tubing fluid added, and the tubes sealed  Bollable sutures are coiled, placed in tubes with the label and tubing fluid added. The tubes are then sealed, placed in a bath of oil and sterilized by means of the same heating technic as for nonbollable sutures	Nonbollable sutures: 97 parts by volume absolute ethyl alcohol, 3 parts by volume sterile water. Potassium mercuric iodide  Bollable sutures: Chemically pure xylene	All sutures labeled sterile are heat sterilized. Copper or any of its compounds is not used
7	Nonbollable and bollable sutures: The catgut is coiled and placed in presterilized glass tubes and then dehydrated. The tubes are submerged in an anhydrous hydrocarbon fluid and autoclaved at a required temperature for a required period of time (time and temperature not given). The sterilization fluid is drained from the tubes and the tubing fluid added. They are then flame sealed. The bollable variety is subjected to a second autoclaving after sealing	Nonbollable sutures: 93% ethyl alcohol with 1:1,000 red mercuric iodide  Bollable sutures: Absolute isopropyl alcohol 50%, benzene 45%, amalie oil 5%	No copper in any form is used in the manufacture of (firm 7) sutures
9	Nonbollable sutures are wound on reels, placed in open tubes and dehydrated. They are then placed in an oil sterilizer and the temperature of the bath brought to 300 F. (148 C.) and held for one hour. After cooling the oil is removed and the tubing fluid added. The tubes are sealed and inspected  Bollable sutures are treated the same except that the ligatures are covered with xylene and sealed prior to heat sterilization (320 F. for one hour)  Iodized sutures are made by treating moist gut in an aqueous iodine solution for a sufficient time to insure a total iodine content of from 12 to 15% in the finished product. The dried polished ligatures are placed on reels in tubes and covered with a storing fluid. These sutures are not heat sterilized	Nonbollable sutures: Pure grain alcohol containing 0.3% potassium mercuric iodide  Bollable sutures: Xylene  Iodized sutures: Chloroform containing 0.3% of resublimed iodine	No copper or copper salt is used  Impregnated with iodine until the sutures contain 12 to 15% iodine
10	Nonbollable sutures: Sutures are dehydrated in vacuum dryers and sterilized by heating in petrolatum oil to the temperature of 320 F. (160 C.) on successive days. This temperature is held for one hour. The tubes are then filled with the tubing fluid and hermetically sealed	Nonbollable sutures: 1% iodine, 3% xylene in absolute alcohol Storing fluid for sutures with needles attached is 40% methyl and 60% ethyl absolute alcohols	Copper is not used in any form
11	Nonbollable sutures: The sutures after dehydration are submerged in a coal tar benzine which has a boiling range of approximately 165 to 180 C. The temperature of this bath is brought up gradually until it reaches 320 F. (160 C.) and is held for one hour. After sterilization the coal tar benzine is replaced with tubing fluid and the tubes are sealed	Nonbollable sutures: Potassium approxl.	No chemical sterilization is employed
12	Bollable sutures are coiled *(sterility control Meloney-Chatfield method number is stamped on each reel), placed in glass tubes and dehydrated. The tubes are then filled with the fluid, hermetically sealed, placed in an autoclave and heat in progressive steps applied to insure sterility.  Nonbollable sutures are coiled *(sterility control Meloney-Chatfield method number is stamped on each reel), placed in tubes, dehydrated, covered with Special Naphtha, placed in the autoclave and heat applied as for the bollable type. After sterilization the Special Naphtha is removed from the tubes with aseptic technic, the tubing fluid added and the tubes sealed in the flame	Bollable sutures: Special Naphtha; boiling point 160-195 C.  Nonbollable sutures: U. S. government formula 42—Denatured alcohol specified by Treasury Department Bureau of Industrial Alcohol to be used in the manufacture of ligatures and sutures.	Chemical sterilization is not employed; intensive heat sterilization used exclusively
14	Nonbollable sutures: the sutures are wound into 3 inch coils dehydrated at a temperature of 107 C. These small coils are placed in a basket and lowered into a bath of cumol. The temperature of this bath is brought to 300 F. (148 C.) and held for one hour. After cooling these coils are removed from the cumol under aseptic conditions and placed in an alcoholic potassium mercuric iodide solution over night. They are then cut to length, wound into smaller coils and placed in small glassine envelops and packed in the final storage jars in a storage fluid	Nonbollable sutures: Storage fluid is formula 42 denatured alcohol: 100 gallons of ethyl alcohol, 80 Gm. of potassium iodide U. S. P. and 109 Gm. of red mercuric iodide	No chemical sterilization employed except as supplied by the tubing fluid

\* The sterility control number stamped on each reel also indicates also stamped on the outside of the finished stock package.

date of manufacture and number of ply. Sterility control number is

dence of goiter in Somerset, it is difficult to escape the conclusion that some other factor or factors must be involved. The relationship between environmental iodine deficiency and the intensity of incidence of goiter is not a perfectly simple one. It is therefore clear that further work on the amount and mode of combination of iodine in soils in relation to the iodine content of herbage grown on them is necessary before a decision can be reached. The possible rôle of variation in the availability of soil iodine is a complicating factor which adds materially to the complexity of the analytic methods necessary.

## Current Comment

### MERCURIAL DIURETICS

Quantitative clinical comparisons of the diuretic action of various mercurials are rare. Sollmann and Schreiber<sup>1</sup> studied in a routine manner the excretion of mercury in clinical treatment and recorded the urinary volume. Data were thus accumulated that seem to furnish good material for a comparative study of diuretic potency. The different preparations were given by intravenous or intramuscular injections. They were classified into four groups: the organic compounds, including mercurosal, merbaphen and salyrgan; the inorganic ionizable compounds, including mercuric bromide, mercury bichloride in oil and mercuric cyanide; the inorganic colloidal compounds, consisting of metallic mercury and mercuric sulfide; and the unclassified compounds flumerin and mercuric salicylate in oil suspension. The overwhelming mass of individual data required simplification and grouping. The figures were presented, therefore, as means, the hourly excretion in successive periods sufficing as a convenient starting point. The charts constructed from these means revealed at first glance the striking directional similarity in practically all the curves between the urinary volume, the excretion of mercury and the concentration of mercury for all the different compounds and for intravenous and intramuscular injections. With a few minor exceptions, the quantitative peak was reached within one or two hours of the time of injection, followed by descent as a parabolic curve with fairly comparable speeds. The chief differences were in the height of the peaks, and for the curve of urinary volume this had a moderate range of from two to five times the normal level. The organic compounds caused somewhat greater diuresis in therapeutic doses, but with regard to the mercury content and especially the amount of mercury excreted the organic compounds were surpassed both by ionizable inorganic and by colloidal compounds. Furthermore, the organic compounds gave somewhat more prolonged periods of diuresis and excretion of mercury than the inorganic compounds injected both by vein and by muscle. The colloidal compounds caused the shortest period of diuresis when injected by vein and the longest period of excretion of mercury when injected intramuscularly.

They caused the longest period of diuresis and the shortest period of excretion of mercury. In general, the differences between the compounds of each group were minor and do not suggest a significant generalization.

### THE SURGICAL EQUIPMENT INDUSTRY IN JAPAN

Before the World War the manufacture of surgical instruments and equipment in Japan was a small industry. During the World War the value of such manufactures increased more than 100 per cent. The present trend of the industry is toward further expansion. According to the U. S. Department of Commerce, practically all the surgical instruments and equipment that are used in Japan are now made there with the exception of artificial eyes (which are still imported from Germany) and a few other less important items. Furthermore, much of the surgical equipment imported from the United States and Germany is imported primarily for duplication purposes. A characteristic of the Japanese industry is that the surgical instruments and equipment is largely manufactured in homes and small workshops, which use family labor or at most only a little hired help. Ten of these households, for instance, may make one type of scalpel, another ten may make another type of scalpel, and still another ten may make glass hypodermic syringes, and so on. The United States Department of Commerce has no official information regarding the wages paid in this industry, but it is possible that skilled workmen may average 3 yen (about 90 cents) a day and unskilled helpers 1.50 yen a day. The number of clinical thermometers made by plants employing more than five workers in Japan in 1934 was 1,884,875. The number of clinical thermometers inspected by the government and approved for domestic sale during 1935 was 1,750,000, while the number of thermometers manufactured and approved for export was 300,000. Surgical instruments exported from Japan during 1935 were valued at more than 2,203,000 yen (about \$630,000), and about 20 per cent of this valuation was exported to North America. In fact, North America imported more Japanese surgical instruments than any other world market, except Asia. The United States in particular has advanced to the position of being one of the leading markets for Japanese surgical instruments and allied products. The manufacture of microscopes in Japan has also made great strides. Japanese microscopes are overtaking the German microscopes in perfection, but the Japanese instruments are still behind in the matter of the finest quality of lenses. The production of laboratory microscopes in Japan varies between 100 and 150 units a month. The importation of Japanese surgical supplies into the United States became decidedly impressive in 1934, and further gains were made in 1935. The export of Japanese surgical products to the United States was started and stimulated in many instances by American buyers who went to Japan and placed orders. The present trend is for the Japanese manufacturers to take over the export trade directly. The Japanese government has taken a keen interest in this industry and is said to be seriously concerned in preventing the production of inferior goods, especially for export.

informs me that the strain is no longer pathogenic. Since this organism is one of the most strict anaerobes and this strain is nonpathogenic, it would seem to be the ideal strain for control work in this test.

11. In order to prove that chemical substances in sufficient strength to inhibit bacterial growth have not been carried over with the suture into the tubes of culture medium, the test organism in a 1:100,000 dilution is planted in all tubes that have remained negative throughout the test. I do not agree with Meleney and Chatfield that this should be only an occasional test.

In cases in which large amounts of mercury or iodine are known to be present, Clock<sup>4</sup> suggests using 10 per cent sodium thiosulfate as the neutralizing fluid. He suggests that this be used in addition to the regular technic so that the thiosulfate will be removed by the distilled water, which is the first step in the regular procedure. I am unable to gather from his paper<sup>8</sup> his exact procedure but, presumably, he then puts the suture through 1 per cent sodium thiosulfate, then to medium. I have found by chemical test that the suture takes up sufficient thiosulfate from the 10 per cent solution and that carrying it subsequently through the 1 per cent solution is not necessary. When using the 10 per cent sodium thiosulfate, I have found that nothing is gained by allowing the suture to soak in distilled water twenty-four hours before placing it in the neutralizer. It has been the policy in the latter part of this survey to place the suture directly into the 10 per cent sodium thiosulfate for twenty-four hours, then into distilled water for an additional twenty-four hours and then into the medium. This has proved very satisfactory, as shown in the case of the firm 8 sutures. We have found that there is 0.0004 Gm. of sodium thiosulfate more per 0.4 Gm. suture weight taken up by the sutures if they are not allowed to soak in distilled water first. Also, all the iodine (15 per cent) in an experimental batch of sutures was neutralized by this method. It has been found that the amount of thiosulfate, after the distilled water washing, which may be carried over into the medium is not bacteriostatic.

In consideration of the British therapeutic substances procedure, the Meleney and Chatfield or any similar technic, one is at once doubtful of the possibility of transferring, several times through the air, anything so large and unwieldy as a catgut suture and expecting it not to become contaminated from the air. Therefore, in making this survey—a combination of the before-mentioned methods being used—the greatest care has been given to guard against such contamination. The room in which the transfers were made was small and could easily be scrubbed down with a disinfectant. All the equipment taken into the room was sterilized. The tubes of medium, neutralizers and wash water were sterilized in cans covered by paper hoods so that no dust might settle on the cotton plugs and be scattered into the air as the plugs were withdrawn and the transfers made. The plugs were kept covered also during the initial incubations until the last transfers had been made.

Another point for consideration is the method used in sterilizing the forceps between transfers. Meleney and Chatfield<sup>3</sup> suggest that the forceps be flamed before the transfer is made. They suggest that they may be dipped in alcohol to insure complete flaming. Clock<sup>8</sup> says "The actual transfer of the sutures is made with a pair of obstetrical dressing forceps which has been

boiled for one-half hour, then immersed in ethyl alcohol and thoroughly flamed. Between each transfer the forceps is immersed in alcohol and thoroughly flamed." Some of the spores found in dust are not killed by boiling and I have found that a much more satisfactory method for the preliminary sterilization is to wrap the forceps in paper and sterilize them in the hot air oven at 170 C. for two hours along with the graduate for the alcohol. Hill,<sup>9</sup> a proponent of the method of dipping instruments in alcohol and flaming them for sterilization, claims that this method will kill anthrax spores. Sanderson<sup>10</sup> found that he could not confirm Hill's work. Since he was unable to kill anthrax spores by alcohol flaming, he attempted to show that the temperature was not high enough for sterilization by dipping an ordinary chemical thermometer in alcohol and allowing it to burn off. He reports a temperature of only

\* Only two available—tested only because they were made prior to the advent of the Meleney-Chatfield technic. It is not implied that only two sutures from a firm are sufficient to establish the sterility of that firm's product.

† The four nonsterile sutures from firm 6 were from one box of twelve sutures obtained from the local market and were known to be old stock. They were manufactured before the present methods of sterility testing were advocated. Sutures from firms 6 and 13 are now made in the same laboratory, but the twelve sutures referred to above were manufactured before the merger of firms 6 and 13 was effected. It is interesting to note that 114 sutures obtained from fresh stock made since 1933 by this firm were sterile.

‡ The two sutures indicated in parentheses showed growth which was of the same type of organism (*Staphylococcus aureus*) found as an air contaminant on the blood agar plates exposed at the time these transfers were made and therefore are not considered as nonsterile sutures.

§ Since these results were obtained, sutures from firm 8 have been withdrawn from the market.

60 C. registered by the thermometer. He states, however, that a mixture of alcohol and formaldehyde solution gave a temperature of 133 C. This would be inadvisable for catgut work, since the introduction of traces of formaldehyde into the medium might be bacteriostatic. Sixty degrees did not seem to be an accurate temperature for alcohol burning on the surface of instruments, nor did Sanderson's method of attacking the problem seem conclusive; therefore an attempt was made to get a more accurate reading of the surface temperature of the forceps by using a small platinum-rhodium-platinum thermocouple. By this means, after the alcohol flaming of forceps the temperature of the surface of the metal was found to be about 180 C. Although sufficient work was not done to satisfy ourselves as to the value of this method of sterilization, it is unlikely that any organisms will be introduced from a pair of forceps which has been sterilized at 170 C. for two hours and flamed between transfers. It must

factory evidence that the licentiate in the preceding year attended "at least one of the two-day educational programs as conducted by the Connecticut Chiropractic Association, Inc., the subjects of such programs being under the supervision of the state board of chiropractic examiners." S. 1114 proposes to limit the retail sale and distribution of barbital, trional, sulfonal, tetronal, paraldehyde and chloral or chloral hydrate or chlorbutanol to sale or distribution on the prescription of a licensed physician, dentist or veterinarian. H. 426 proposes that no hospital which receives appropriations from the general assembly shall require any nurse to work more than eight hours a day. S. 1113 and H. 1440, to amend the medical practice act, propose to permit the licensing of teachers in legally incorporated and reputable medical colleges even though they are not citizens of the United States nor have filed written declaration of their intention of becoming citizens. S. 1115 and H. 1445, to amend the medical practice act, propose to eliminate the \$2 fee now charged in connection with the annual registration of practitioners of medicine, osteopathy, midwifery, chiropractic, naturopathy, chiropody and nursing.

### DISTRICT OF COLUMBIA

**Personal.**—Dr. Arthur C. Christie, clinical professor of radiology, Georgetown University School of Medicine, has been made an honorary member of the German Society of Roentgenologists.—Oliver L. Fassig, Ph.D., retired meteorologist of the U. S. Weather Bureau, who had recently finished a book on the climate of Puerto Rico, died December 6 from the effects of injuries received in an automobile accident November 20.—Mr. Watson Davis, director of Science Service, received a fellowship in the American Institute of the City of New York at a meeting February 4.

**Medical Bills in Congress.**—*Bills Introduced:* S. 1506, introduced by Senator Glass, Virginia, proposes to provide for the issuance of a license to practice chiropractic in the District of Columbia to Russell V. Pemberton. H. R. 4806, introduced by Representative Norton, New Jersey, proposes to require each physician, midwife, or other person in attendance on any case of childbirth to administer immediately in the eyes of the baby a 1 per cent solution of silver nitrate or other preparation suitable in the opinion of the health officer for use as a prophylactic against inflammation of the eyes of the new-born baby. Persons treating human ailments by prayer or spiritual means as an exercise or enjoyment of religious freedom are to be exempt from this requirement. H. R. 4850, introduced by Representative Dirksen, Illinois, proposes to amend the optometry practice act of the District of Columbia so as to permit the operation of an optometric department in a mercantile establishment by any individual, firm, partnership or corporation if the department is under the supervision, direction and management of a regularly licensed and registered optometrist. H. R. 4876, introduced by Representative Lea, California, proposes to provide for the issuance of a license to practice the healing art in the District of Columbia to Dr. Frederick W. Didier. H. R. 4982, introduced by Representative Robertson, Virginia, proposes to provide for the issuance of a license to practice the healing art in the District of Columbia to Dr. William Justin Olds.

### GEORGIA

**The Block Memorial Lecture.**—Dr. Henry W. F. Woltman, professor of neurology, University of Minnesota Graduate School of Medicine, Rochester-Minneapolis, delivered the E. Bates Block Memorial Lecture in Atlanta, January 28. His subject was "Postoperative Neurologic Complications." The lecture is delivered under the auspices of the Fulton County Medical Society.

**Bills Introduced.**—H. 287 proposes to forbid the retail sale and distribution of any article, device, drug or medicinal preparation primarily manufactured for, or which may be used for the prevention of venereal diseases and infections, except by licensed physicians in their practice and by registered pharmacists. H. 299 proposes to prohibit the retail sale or distribution of barbituric acid, amytal, allonal, luminal, veronal, or sodium amytal, except on the written prescription of a licensed physician, dentist, or veterinarian.

**The Fischer Awards.**—The Fulton County Medical Society announces the names of the winners of the annual L. C. Fischer Awards for 1936. Dr. Leila Alice Daughtry-Denmark received the prize for the paper demonstrating the most original work for her work on "Studies in Whooping Cough Diagnosis and Immunization." Drs. Amey Chappell and Frank Lee Bivings won the prize for the best written paper. Their subject was "Anemia and Pregnancy: A Three Year Study on Negro

Women." It was also announced that these awards, \$100 each, which were established by Dr. Luther C. Fischer, Atlanta, will be permanent.

### IDAHO

**Bills Introduced.**—H. 192 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. H. 213 proposes to authorize the establishment, construction and maintenance by the state of a hospital for the care of and treatment of persons suffering from tuberculosis, provided that a grant of 45 per cent of the cost of constructing and equipping the hospital is made by the United States government.

### ILLINOIS

**Bills Introduced.**—H. 114 and H. 142 propose, as a condition precedent to the issuance of licenses to marry, that both parties to the proposed marriage present a physician's certificate that they are "free from venereal diseases as nearly as can be determined by a thorough examination and by application of the recognized clinical laboratory tests of scientific search." H. 187 proposes to authorize any area of contiguous territory lying wholly within one county, but entirely outside the corporate limits of any city, to be incorporated as a tuberculosis sanatorium district. The affairs of such district shall be managed by a board of three directors, appointed by the chairman of the board of supervisors of the county in which the district is situated. The directors are to have power to establish and maintain a tuberculosis sanatorium, and branches, dispensaries, and other auxiliary institutions connected with the sanatorium, for the use of the inhabitants of the district in the treatment and care of persons afflicted with tuberculosis. H. 121, to amend the state uniform narcotic drug act, proposes (1) so to define "narcotic drugs" as to include "amytal, luminal, veronal, barbital, acid diethylbarbituric, or any of its salts, derivatives, or compounds of a [sic] foregoing substances, or any preparation or compound containing any of the foregoing substances, or its salts, derivatives or compounds, or any registered, trade marked or copyrighted preparation or compound registered in the United States patent office containing more than four grains to the avoirdupois or fluid ounces of the above substances," and (2) to provide that a prescription for phenobarbital or any preparation, mixture or compound of phenobarbital may be refilled.

### INDIANA

**Bill Introduced.**—H. 297 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic. Chiropractic is defined "as the science of locating and correcting any interference with nerve transmission or expression." A license to practice chiropractic is not to confer on a licentiate the right to practice obstetrics, surgery, prescribe drugs, or administer anesthetics. A licentiate is to be permitted to use the designation "Dr.," "doctor," or symbols designating his "profession," provided such designation is used in such a manner as to indicate that the licentiate is a chiropractor.

### IOWA

**Bills Introduced.**—S. 154 proposes to repeal the present laws regulating the possession and distribution of narcotic drugs and to enact a bill which is denominated as the uniform narcotic drug act. The bill, however, departs from the uniform narcotic drug act in at least one important particular. It omits the provisions of the uniform narcotic drug act intended to limit the gross quantity of the habit-forming drug a person can buy in exempt preparations within a forty-eight hour period. S. 146 proposes to authorize the formation of corporations to establish, maintain and operate nonprofit hospital service plans, whereby care may be provided by such corporations or by any hospitals, to such of the public as become subscribers to said plan, under contracts which entitle each subscriber to hospital care. S. 163 proposes to permit a taxpayer in computing his net taxable income to deduct from the gross income the amount actually expended by him during the past year for medical, hospital and surgical services.

### KANSAS

**Bill Introduced.**—H. 308 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

**Dr. Snyder Named to Board of Regents.**—Dr. Howard L. Snyder, Winfield, president of the Kansas Medical Society, has been appointed by the governor a member of the board of regents of Kansas, for a term of four years. The board has under its supervision all affairs incident to state schools.

manufactured. Of the thirty nonsterile sutures found in this survey, twenty-five were from the 220 old sutures examined and five were from the 800 sutures of recent manufacture.

While it is apparent that there is need for adequate control of the sterility of catgut sutures manufactured and sold in America, I am of the opinion that the publication of the results of Meleney and Chatfield and of Clock may have had considerable influence in improving the quality of sutures now being manufactured, so far as sterility is concerned.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

- (1) GRIDLEY FAST FROZEN ORANGE ICE
- (2) GRIDLEY FAST FROZEN LEMON ICE
- (3) GRIDLEY FAST FROZEN PINEAPPLE ICE
- (4) GRIDLEY FAST FROZEN MINT ICE
- (5) GRIDLEY FAST FROZEN RASPBERRY ICE
- (6) GRIDLEY FAST FROZEN STRAWBERRY ICE
- (7) GRIDLEY FAST FROZEN ORANGE SHERBET
- (8) GRIDLEY FAST FROZEN LEMON SHERBET
- (9) GRIDLEY FAST FROZEN PINEAPPLE SHERBET
- (10) GRIDLEY FAST FROZEN MINT SHERBET
- (11) GRIDLEY FAST FROZEN RASPBERRY SHERBET
- (12) GRIDLEY FAST FROZEN STRAWBERRY SHERBET

*Manufacturer.*—Gridley Dairy Company, Inc., Milwaukee.

*Description.*—(1) Basic frozen mix containing water, sugar, citric acid and gelatin; flavored with emulsions of orange oil (U. S. P.) and glycerin, and lemon oil, water, gum arabic, and glycerin, and U. S. Department of Agriculture certified color.

(2) Basic frozen mix flavored with lemon oil emulsion.

(3) Basic frozen mix flavored with crushed pineapple.

(4) Basic frozen mix flavored with emulsion of oil of peppermint (U. S. P.) and glycerin, and U. S. Department of Agriculture certified color.

(5) Basic frozen mix with fresh or frozen raspberries and U. S. Department of Agriculture certified color.

(6) Basic frozen mix with sweetened cold pack strawberries and U. S. Department of Agriculture certified color.

(7) Same as (1) with added ice cream mix (THE JOURNAL, Sept. 7, 1935, p. 801).

(8) Same as (2) with added ice cream mix.

(9) Same as (3) with added ice cream mix.

(10) Same as (4) with added ice cream mix.

(11) Same as (5) with added ice cream mix.

(12) Same as (6) with added ice cream mix.

*Manufacturer.*—The ingredients of the basic frozen mix are thoroughly mixed, frozen, packaged and hardened as described for Gridley Fast Frozen Ice Cream (THE JOURNAL, Sept. 7, 1935, p. 801). In the case of sherbets, the ice cream mix is added when the mixture is partly frozen.

*Analysis* (submitted by manufacturer).—(Orange Ice) moisture 66.9%, total solids 33.1%, ash 0.03%, fat 0.0%, protein

(N  $\times$  6.25) 0.1% and carbohydrates (by difference) 32.9%. (Orange Sherbet) moisture 65.7%, total solids 34.3%, ash 0.10%, fat 1.0%, protein (N  $\times$  6.25) 0.3% and carbohydrates (by difference) 33.0%.

*Calories.*—1.3 per gram; 37 per ounce.

### SEXTON BRAND APRICOTS, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned apricots, packed in juice.

*Manufacturer.*—Santa Clara Valley apricots, sprayed only before blossoming period, are harvested at maturity, inspected, washed, graded, cut, pits removed, sorted, again washed, and placed in cans, mechanically filled with juice, exhausted, sealed and processed at 88 C.

*Analysis* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 86.2%, total solids 13.8%, ash 0.7%, fat (ether extract) 0.1%, protein (N  $\times$  6.25) 0.6%, crude fiber 0.4%, carbohydrates (by difference) 12.0%.

*Calories.*—0.51 per gram; 14 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

### CHOC-LADE DAIRY DRINK SYRUP

*Manufacturer.*—Siren Mills Corporation, Chicago.

*Description.*—A syrup containing sucrose, invert sugar, cocoa, starch-free powdered cane sugar, salt and vegetable emulsifying agent.

*Manufacturer.*—Formula: Water 33.9%, sucrose 27.4%, invert sugar 23.6%, cocoa 8.2%, starch-free powdered cane sugar and dried extracts of marine plants 6.7%, salt 0.23%, vanillin 0.07%. Selected cocoa beans are roasted, and the shells are removed; nibs are blended, and milled to produce chocolate liquor. Some cocoa butter is removed, leaving a cocoa cake which is pulverized and bolted through fine silk.

Starch-free powdered cane sugar, dried extract of marine plants and 40 per cent of the water are mixed until a smooth suspension is obtained. Remaining water, sugar, cocoa, invert sugar and salt are mixed, boiled, and vanillin is added; the mixture is cooled slightly and the suspension of sugar and extracts is added. Constant agitation is continued until the batch is cool. The syrup is canned.

*Analysis* (submitted by manufacturer).—Moisture 39.7%, ash 0.7%, fat (ether extract) 1.2%, protein (N  $\times$  6.25) 1.2%, reducing sugars as invert sugar 17.9%, sucrose (copper reduction method) 33.0%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 56.9%, caffeine and theobromine 0.12%.

*Calories.*—2.43 per gram; 69 per ounce.

*Claims of Manufacturer.*—For preparation of special Choc-Lade beverage in accordance with specific license contracts and conditions of preparation.

1. COLONIAL BRAND PINEAPPLE JUICE
2. SOUTHERN MANOR BRAND CRUSHED, SLICED AND SPEARS PINEAPPLE

*Distributor.*—D. Pender Grocery Co., Norfolk, Va.

*Packer.*—Hawaiian Pineapple Company, San Francisco.

*Description.*—1. Canned Hawaiian pineapple juice retaining in high degree the natural vitamin content; the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p. 1769).

2. Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole canned pineapple (THE JOURNAL, April 8, 1933, p. 1106).

### CLOVER FARM BRAND TOMATO JUICE

*Distributor.*—Clover Farm Stores, Cleveland.

*Packer.*—Vincennes Packing Corporation, Vincennes, Ind.

*Description.*—Pasteurized tomato juice with added salt; retains in high degree the vitamin content of the raw juice; the same as Alice of Old Vincennes Tomato Juice (THE JOURNAL, Feb. 20, 1932, p. 640).

**Bills Passed.**—The following bills have passed the senate: S. 83 proposing to repeal the present law relating to the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act; and S. 64, proposing to permit courts, in any proceeding in which it may be material to prove nonpaternity or to prove that blood or trace of blood is not that of a certain person or persons, to require any person whose relationship or blood identity is material to the issue to submit to blood grouping tests and to make the results of such tests admissible in evidence when such tests tend to establish nonpaternity or to negative the possibility of such blood or blood trace being that of such person.

### NEBRASKA

**Bills Introduced.**—Bill No. 159, to amend the chiropractic practice act, proposes to define chiropractic "as the science of locating and correcting interference with nerve transmission and expression between brain cells and tissue cells." Bill No. 168 proposes so to amend the state narcotic drug act as to provide that "Narcotic drugs" means marihuana leaves and every substance neither chemically nor physically distinguishable from them." Bill No. 195, to amend the workmen's compensation act, provides that if the medical treatment to be rendered an injured employee at the employer's expense exceeds \$125, the authority of the compensation court for such additional service must first be obtained. The bill further provides that that court may authorize expenditure for medical and hospital services and medicines for the purpose of restoring the injured worker to health up to \$2,000.

### NEVADA

**Bill Introduced.**—A. 104 proposes to create a board of physiotherapy examiners and to regulate the practice of physiotherapy. The board is to consist of three "medical doctors" appointed by the governor. Physiotherapy is defined as "the use of physical remedies in treatment of disease or disability as taught in schools, colleges and institutions of physiotherapy." An applicant for such a license must be of good moral character and be a graduate of a school, college or institution teaching physiotherapy and giving a course of at least three years of eight months each in anatomy, physiology, pathology, sanitation and hygiene, chemistry, gynecology and obstetrics, symptomatology, bacteriology, diagnosis, laxatology and massage, phlebotomy, antiseptic and aseptic and the theory and practice of physiotherapy.

### NEW HAMPSHIRE

**Bill Passed.**—S. 34 has passed the senate proposing that an action for malpractice must be brought within two years after the cause of action accrues and not afterward.

### NEW JERSEY

**Bill Introduced.**—S. 139 proposes to appropriate \$2,500 to the department of health to enable it to care for, maintain or isolate indigents who are carriers of the causative agents of typhoid fever, paratyphoid fever or other diseases.

### NEW MEXICO

**Bill Introduced.**—H. 127 proposes to create a board of chiropody examiners and to regulate the practice of chiropody. The bill defines chiropody as "the diagnosis, electrical, medical and surgical treatment of all ailments of the foot and leg, other than the amputation of the foot, leg or toes."

**District Health Officers' Conference.**—A conference of district health officers of the state was held in Santa Fe, January 21-23. Subjects discussed included nursing supervisors, antepartum and child health clinics, midwifery, sanitation, slaughterhouse and meat transportation regulation, spray residues and administrative problems. A resolution was adopted thanking the press of the state for space given to news and feature articles on public health and another requesting the Bureau of the Census to furnish franked envelopes for the forwarding of birth and death certificates to health departments by subregistrars.

### NEW YORK

**Five Hundred Cases of Scarlet Fever.**—The town of Owego, Tioga County, has passed an ordinance requiring pasteurization of all milk sold there. The legislative action came as a result of a recent outbreak of about 500 cases of scarlet fever traced to raw milk. Investigation revealed that a dairy from which it was suspected that the epidemic started had bought a cow a few days before the outbreak began. Immediately prior to that time the cow had been on a farm where

three cases of scarlet fever had occurred. One of these was in a boy who had milked the cow. Sale of milk was stopped and the number of cases rapidly declined.

**Bills Introduced.**—S. 594 and A. 928 propose to enact a "consumer's protection act" to regulate the traffic in foods, drugs, cosmetics or health devices and to prevent the manufacture and sale of such articles if they are adulterated or misrepresented." S. 615, to amend the law requiring the licensing of laboratories and other places in which live pathogenic germs are handled or cultivated, proposes to require such licensure from all places "where live pathogenic micro-organisms or viruses other than vaccine virus are handled or cultivated." The bill also proposes to prohibit all persons, other than licensed practitioners of medicine, dentistry, or veterinary medicine or persons acting under the direct supervision of the licensed practitioners noted, to possess or cultivate live pathogenic micro-organisms or viruses other than vaccine viruses unless such persons have satisfied the state commissioner of health that such micro-organisms or viruses in their possession will not become a menace to the public health and unless they hold a permit issued to them by the state commissioner of health. The bill also proposes that all live pathogenic micro-organisms or viruses other than vaccine virus when given away or sold shall bear a label on the container showing the registration number of the distributor which has been issued by the state department of health for the handling of pathogenic micro-organisms or viruses, the name of the person obtaining the material and the destination of the pathogenic micro-organisms or viruses. A. 892 proposes a system of compulsory and voluntary health insurance, the benefits of which are to consist of cash and all forms of medical, surgical, and dental services. The compulsory insurance in the bill is to apply to all employees except (1) persons employed at other than manual labor and receiving wages in excess of \$60 a week, (2) farm laborers and (3) persons employed in the personal or domestic service of an employer having less than three employees engaged in such service. These persons excluded from the compulsory insurance of the bill, however, may elect to come under the voluntary insurance offered in the bill. This bill appears to be identical with the health insurance bill prepared and distributed by the American Association for Social Security, Abraham Epstein, Secretary. S. 746 and A. 1051 authorize the establishment of three state cancer hospitals under the control of the department of health. The site of one of such hospitals is to be in the city of Buffalo and those of the other two, so far as practicable, shall be, respectively, one in the central or south central and the other in the eastern region of the state. S. 745 requires the appropriate public health official to provide medical care for the indigent sick in their homes whenever necessary. A person in need of medical care in the home is to be entitled to choose his family physician. When a person in need of medical care does not elect to choose a physician, the appropriate public welfare official shall select a physician to attend him. S. 755 proposes to establish in the department of health a division of syphilis control, apparently to supplant the existing division of social hygiene.

### New York City

**The City's Health in 1936.**—A slight increase in the death rate of New York in 1936, 10.5 per thousand of population as compared with 10.3 in 1935, is recorded in the annual report of the health commissioner, Dr. John L. Rice. This small increase is probably not significant, the report says, because it is based on a population estimate that may be incorrect. The infant mortality was the lowest ever recorded in the city, 45.3 per thousand live births. A low rate of 2.2 deaths from diphtheria reflects the efforts put forth in the diphtheria prevention campaign begun in 1929, when the death rate was 27.4. Only thirty-seven children died of diphtheria in New York in 1936, compared with 717 in 1927. The tuberculosis death rate has declined but little in the past three years; in 1936 it rose to 56.6 from 54.4 in 1935. Pneumonia deaths increased to a rate of 89 after dropping to 87.5 in 1935. The rate is on a much lower plane, however, than the rate of a few years ago; for instance, in 1933 it was 107.3. It is believed that the reduction is the result of more effective methods of treatment. An outbreak of meningitis in which 243 deaths occurred in 1935 continued in 1936 with 218 deaths; in 1934 there were only seventy-three deaths. Only thirty-eight cases of poliomyelitis were reported during 1936, in contrast to 2,054 the previous year. There were fewer deaths from measles, whooping cough and scarlet fever, but these diseases remain serious menaces, Dr. Rice pointed out. Appendicitis deaths, which distinctly decreased in 1935, rose to 14.3 per hundred thousand of population in 1936. Chronic diseases of later life were responsible for about 50

nic on the part of the serologists who are responsible for the performance of these tests. Perhaps the utilization of minor modifications in technic for a given test explains these differences in performance, especially in laboratories not equipped for careful investigations. The leading serologists of the country who have described reliable tests should insist that all laboratories doing routine work follow to the letter the technics which have been described for their own tests.

The relatively low ratings for specificity and sensitivity in some of the performances indicate the need for a system of periodic comparative examination of serologic tests. Such comparative examinations should be made on both a clinical and a serologic basis. The committee has recommended the establishment of such a system of comparative examinations for all state laboratories, and the necessary provisions for this work are being made by the Public Health Service. Every state laboratory in the country should avail itself of the opportunity to determine the efficiency of the performance of its tests and should set up the necessary organization to conduct a separate evaluation of serologic tests for syphilis performed by all municipal and private laboratories within its boundary. Only in this way will an efficient and practical system be established to insure the performance of reliable serodagnostic tests in the United States at all times.

#### ENDEMIC GOITER AND IODINE CONTENT OF WATER, MILK AND PASTURE

In a recent bulletin of the Medical Research Council of Great Britain appears the report<sup>1</sup> of investigations directed toward a possible explanation of the remarkable differences in the incidence of thyroid enlargement among girls of school age in English counties. Two districts were selected for study which were known to exhibit differences in the frequency of occurrence of goiter. Certain rural areas of the counties of Somerset and Suffolk were chosen. Rural schools in which the average attendance varied from about forty to 150 children were inspected. It was considered likely that schools of such size would be found in villages in which probably only one or two farmers provided the main part of the milk supply. Such restriction was deemed necessary because of agreement that milk samples from not more than two farms in the neighborhood of any rural school could be analyzed. The survey was confined to girls, as it was assumed that the incidence in the female sex alone would provide a sufficiently reliable indication of the relative prevalence of goiter. The girls attending school aged from 6 to 14 years were marshaled in groups of ascending age and passed one by one in front of the observer, who, from a general inspection of the neck, decided whether the thyroid

gland was visibly enlarged. Attempt was made to classify the thyroid into the four categories recognized by Stocks, namely: (0) impalpable thyroids, (1) thyroids palpable but no visible enlargement on inspection, (2) thyroids that showed visible enlargement but not sufficient to produce gross deformity in shape of neck, and (3) thyroids sufficiently large to be termed "goiter" beyond question. In all cases an effort was made by gentle palpation and a pair of graduated calipers to obtain an approximate measure of the greatest transverse breadth of the gland. After inspection was completed in each school an attempt was made to obtain the names and addresses of the one, two or three farmers in the neighborhood who supplied the milk to the village or district or to the children in the school.

For the whole series of 120 schools surveyed in the Somerset district, the percentage of girls with large thyroids averaged 35.7. From 6 to 8 it was found in 25 per cent, from 9 to 11 in 37 per cent, and from 12 to 14 in 46.8 per cent.

In the smaller number of schools analyzed in Suffolk the average incidence of enlarged thyroid gland among girls from 6 to 14 was only 3.7 per cent. The percentages varied, however, from 1.4 in girls from 6 to 8 to 6.9 in girls from 12 to 14 years of age. After these preliminary observations, villages were selected from which samples of the various materials were to be collected. The aim was to choose those villages in the respective districts which had a high or low incidence of thyroid enlargement combined with the greatest restriction of local sources of food and water supply. The iodine in the water, milk and pasture grass was analyzed according to Harvey's method and the tests were carried out in duplicate. The only significant difference in iodine content of these supplies between the two districts chosen lay in the iodine content of the water. The average iodine content of the water in Somerset was thus 2.9 micrograms per liter and in Suffolk 8.2 micrograms per liter when a few grossly discordant results were excluded. Even when the latter were included the difference was striking, the averages then being respectively 6.0 and 10.6 micrograms per liter. The analysis of the milk and pasture samples led to results that were identical for the two districts within the limits of error of the method. The daily iodine requirements of a child is believed to lie between 25 and 50 micrograms.

When considered in relation to the analytic results contained in the present report, it is difficult to conclude with confidence either that the environmental deficiency of iodine in Somerset is so intense as to be solely responsible for the high incidence of goiter or that the striking difference between the incidence of goiter in Somerset and in Suffolk can be referred exclusively to the difference in the iodine content of the respective waters. Although doubtless true that insufficient intake of iodine is at least partly responsible for the high inci-

1. Committee upon Iodine Deficiency and Thyroid Disease: The Relationship of the Iodine Content of Water, Milk and Pasture to the Occurrence of Endemic Goiter in Two Districts of England, Medical Research Council Special Report Series 217, H. M. Stationery Office, 1936.

## SOUTH DAKOTA

**Bills Introduced.**—S. 139, to amend the workmen's compensation act, proposes to permit the injured worker to select his own physician or hospital to treat and care for him at the employer's expense. The bill also proposes to limit the employer's liability for medical services to \$100 and to limit his liability for hospital services to \$100. H. 75 proposes to make it the duty of the governing agencies of the several public and parochial schools in the state to enforce the regulations of the state board of health requiring all teachers to obtain each year a certificate from a licensed physician showing the absence of active tuberculosis before they will be allowed to teach. S. 205 proposes to create a board of healing arts to consist of the president of the South Dakota university, the state superintendent of public instruction and the president of the state college. It is to be the duty of this board "to prescribe the educational qualifications and studies which shall have been pursued by any applicant to any state board for examination pertaining to the healing art and to enact regulations and rules for examining applicants before said board." No applicant for a license to practice any form of the healing art is to be allowed to appear before any "professional" examining and licensing board without first having obtained a certificate from the board of healing arts that he has pursued the studies designated by the board and has passed examinations given by the board.

## TENNESSEE

**Bills Introduced.**—S. 367 and H. 630 propose to require applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination and licensure by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology, to be given by the department of education. S. 368 and H. 631, to amend the medical practice act, propose (1) to make it possible for all members of the board of medical examiners to be appointed without regard to their school of practice; (2) to provide that members of the board be appointed from a list of names submitted by the Tennessee State Medical Association; (3) to provide that the term of office of members of the board be six years, instead of four; (4) to eliminate the requirement that members of the board representing each separate school of practice shall have the right to examine all applicants of that school in the branches peculiar to the teachings of that school and to substitute therefor a provision that each applicant coming before the board for examination must present evidence of graduation from a medical college which requires, as a prerequisite to admission thereto, two years of collegiate work, including physics, chemistry, and biology; (5) to increase to \$50 the fee for the issuance of a license by reciprocity; (6) to increase the fee for a license issued after examination to \$25; (7) to provide a stated procedure to be followed in revocation or suspension proceedings; (8) to add the following to the list of acts the commission of which shall be deemed unprofessional conduct and grounds for the revocation of a license: advertising statements that might be calculated to deceive or mislead the public; employing or making use of advertising, solicitors, radio announcers, entertainers or lecturers; guaranteeing or warranting operations; giving testimonials concerning the supposed virtue of secret therapeutic agents; promising radical cures or boasting of, prescribing or employing secret methods of treatment or the exhibition of certificates of skill or success in the treatment of diseases; the conviction of any violation of the Harrison Antinarcotic Act; and the conviction of any felony; and (9) to make it unlawful for any one not a licensed physician to use x-ray or electric coagulation for examination or for the diagnosis and treatment of diseases, provided that this shall not be construed to apply to x-ray technicians working under the direction of a licensed physician or dentist.

## TEXAS

**Bills Introduced.**—S. 229 and S. 230 propose to prohibit the manufacture, or sale or other distribution of any article of food to which has been added formaldehyde, boric acid or borates, benzoic acid or benzoate, sulfurous acids or sulfites, salicylic acid or salicylates, abastol, beta naphthol, fluorine compounds, dulcin, glucin, cocaine, sulfuric acid or other mineral acid except diluted phosphoric acid, any preparation of lead or copper or other ingredients injurious to health. Nothing in the bill, however, is to be construed as prohibiting the sale of foods or drinks preserved with one tenth of one per cent of benzoate of soda, or the equivalent benzoic acid, when a statement of such fact is plainly indicated on the label. The bill also proposes to authorize the state board of health to promulgate regulations limiting the quantity of oxides of sulfur and other

bleaching, clarifying or refining agents that may be used in bleaching, clarifying or refining fruits, vegetables and other foods. S. 249 proposes to prohibit the sale of adulterated or misbranded foods, drugs, cosmetics or devices. H. 474 proposes that no hospital shall be exempt from taxation unless it allows and makes "available the equal, constant and complete use of its property and facilities to each and every reputable physician and/or surgeon who has been qualified and licensed to practice as a physician and/or surgeon by the State Board of Medical Examiners."

## UTAH

**Bills Introduced.**—House Concurrent Memorial No. 5 proposes to memorialize the legislatures of the several states of the United States to enact laws designed to eradicate venereal disease and particularly to require a medical certificate of freedom from venereal disease as a prerequisite to marriage. H. 161 proposes to prohibit the retail sale or distribution of any device, appliance, or medicinal agent used in the prevention of venereal disease except by licensed pharmacists, physicians or osteopaths. H. 163, to amend certain provisions of the law authorizing the department of registration to examine and license applicants for licenses to practice any form of the healing art and to revoke and suspend licenses for causes stated, proposes (1) to require the department to provide a stenographer to take down the testimony of all proceedings to revoke or suspend a certificate and to require the department to furnish a transcript of such record on the payment of a stated fee; (2) to require the committee presiding at a revocation or suspension proceeding to present to the director of the department of registration a written report of its findings and recommendations, to require a copy of that report to be served on the affected licensee, and to require the affected licensee to present to the department a motion in writing for a rehearing within twenty days after receipt of the committee's findings and recommendations; and (3) to vest in the district court of the county wherein the licensee resides power to review any order of revocation or suspension, provided suit is commenced within twenty days after the registrant's receipt of notice of the order of revocation or suspension.

## WASHINGTON

**Bills Introduced.**—S. 261 proposes that any professional or vocational group of persons required by law to pay a license fee or pass examinations shall have the right to form an association or society with quasigovernmental powers. Such an association when formed "shall take over the powers now granted to the director of licenses pertaining to examinations of new applicants, the hearing of grievances against any member, and any and all other laws which pertain to the regulation and governing of such organizations." H. 385 proposes to authorize employers to contract to supply their employees medical and surgical treatment, nursing and hospital services contingent on sickness or injury not sustained in the employment and to collect or retain a portion of their employees' wages for that purpose. H. 386 authorizes the formation of such corporations to transact business as hospital associations. Such corporations are to be permitted to contract with subscribers for the furnishing of medicines, medical and surgical care and attention, nursing care, hospital care and dental service contingent on sickness or accident. H. 388 proposes to grant to physicians, nurses and hospitals treating persons injured through the fault of others, liens on any claims, rights of action, judgments or compromises accruing to the injured persons because of their injuries. S. 209, to amend the state narcotic drug act proposes (1) so to define "narcotic drugs" as to include "dilaudid, cannabis sativa (a species of which is marihuana) . . . barbitol"; (2) to require a dispenser of narcotic drugs to preserve prescriptions for such drugs for five years; (3) to authorize the state board of health to purchase and dispense narcotic drugs at clinics in such quantities and at such intervals as it may deem necessary to narcotic addicts who are bona fide residents of the state and who in the opinion of the board of health cannot be cured of their addiction by quarantine and detention. S. 213 and H. 377 propose to enact a "state food, drugs, and cosmetics act," to prevent the manufacture, shipment and sale of adulterated or misbranded food, drugs and cosmetics.

## WEST VIRGINIA

**Bills Introduced.**—H. 159 proposes that "no person convicted of a felony . . . and sentenced to confinement in the penitentiary . . . shall be paroled, permitted to go at large or conditionally pardoned before the expiration of the maximum term of his or her sentence until he or she has been made sexually sterile." H. 250 proposes, as a condition pre-

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARIZONA

**Bills Introduced.**—S. 101 proposes to establish a state department of health, to consist of the state board of health and the state commissioner of public health. The state board of health is to consist of five members, three of whom must be members of the Arizona State Medical Association. The board of health is to appoint the commissioner of health, who is to be the executive officer of the department. The board is to adopt policies, rules and regulations for the government of the state department of health. The state department is to maintain basic divisions in epidemiology, vital statistics, sanitary engineering, laboratories for the diagnosis and control of diseases, maternal and child hygiene, and such other divisions as may be necessary to promote the public health. The bill also proposes a set-up for county and district departments of health. S. 131 proposes to regulate the practice of midwifery and to prohibit such practice except by physicians or persons licensed by the state board of health. An applicant for a license to practice midwifery must be not less than 21 years of age, be able to read and write, to show constantly evidence of habits in cleanliness and to possess a diploma from a school for midwives recognized by the state superintendent of public health or to have attended, under the instruction of a duly licensed physician, not fewer than twenty mothers and new-born infants. A licensed midwife may practice midwifery in cases of normal delivery but in cases in which delivery has not been accomplished in twelve hours she must summon a physician. A midwife is to be forbidden to make vaginal examinations, to use instruments of any kind to aid delivery, to assist labor by any artificial, forcible or mechanical means, or to administer, advise, prescribe or employ dangerous or poisonous drugs.

### ARKANSAS

**Bills Introduced.**—S. 270 proposes to authorize the sexual sterilization of habitual criminals. A habitual criminal is defined as a person who has been two or more times convicted to final judgment for the commission of a felony. S. 277 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. H. 383 proposes to create for a period of twenty-five years a board to be known as the "Medical Investigation Commission," to consist of seven members appointed by the governor, each member to be a licensed physician. It is to be the duty of the board to investigate the credentials of all physicians whose licenses to practice in Arkansas have been issued since January 1, 1915.

### CALIFORNIA

**Bills Introduced.**—Assembly Constitutional Amendment No. 35 proposes to amend those provisions of the constitution relating to the practice of chiropractic, among other things, so as to define "chiropractic to be the art and science of locating and adjusting by hand to restore to normal any abnormal anatomic relation for the purpose of removing interference with the transmission of nerve force and also include all natural, drugless, mechanical, hygienic and sanitary measures incident to the care of the body when administered previous to or subsequent to an adjustment." A. 2116 proposes that wherever it shall be relevant to the prosecution or defense of an action, the trial court shall order any party to the action and the child of any such party to submit to one or more blood grouping tests, the results of which can be received in evidence only where definite exclusion is established. A. 2160 proposes that in any county in which a county hospital has been established, any expectant mother who is unable to pay for her necessary care must be admitted and the cost of her maintenance and care is to be paid by the county of her residence. A. 2249, to amend the workmen's compensation act, proposes that "any employee dissatisfied for whatever reason with the medical, surgical or hospital treatment provided by the employer, shall have the right to obtain medical, surgical or hospital treatment of his own choice, at the expense of the employer." A. 2313 proposes to direct the department of institutions to provide and maintain adequate hospitals and hospital facilities for the care and treat-

ment of inebriates. A. 2569 proposes to enact a law relating to gonorrhea and syphilis. The bill proposes that every person in California over 18 years of age must submit annually to an examination to ascertain his or her freedom from gonorrhea or syphilis. If such examination reveals the presence of a venereal disease it is to be a misdemeanor for the person to refuse or to neglect to undergo necessary treatment. All persons in the state over 18 must be in the possession of a card to be known as a "G-S card," which must be renewed annually. The bill also proposes that every person marrying in the state must be in the possession of a certificate obtained within three days preceding the marriage indicating that there is no danger that such person can communicate a venereal disease to the other party to the marriage or to possible offspring. A. 2589 proposes to create a state board of eugenics, to consist of the director of the state department of institutions, the director of the state department of public health, and the director of the state department of social welfare. This board is to pass on applications for eugenic sterilization made by the superintendent or managing director of any state institution with respect to certain socially inadequate inmates in his custody or care. A. 2731, to amend the chiropractic initiative act, proposes, among other things (1) to define chiropractic as "the science and art of location and removal of any nerve interference or subluxations and their effects," and (2) to provide that a license to practice chiropractic shall authorize the holder to practice chiropractic as just defined and, in addition, "to diagnose and treat disease, deformities or other physical or mental conditions of human beings with the aid of heat, light, water, color, electricity, oils, massage and diet."

### COLORADO

**New Division of Tuberculosis.**—The Colorado State Board of Health has created a division of tuberculosis control and appointed Dr. Alfred R. Masten, Denver, as director. One phase of a special program of tuberculosis control has already been instituted, that of supplying physicians of the state with information on the recent diagnostic and therapeutic developments in the field of tuberculosis, the necessity of complete morbidity reports, and the importance of sputum examinations in suspected cases of tuberculosis.

**Bills Introduced.**—H. 529 proposes to make citizenship a prerequisite to the right to obtain licenses to practice medicine and surgery, chiropody, optometry, chiropractic or any of the healing arts. H. 544 and S. 382 propose to require all applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination and licensure by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology, to be given by a board of examiners in the basic sciences. Members of the board must be full time paid professors or associate or assistant professors, teaching the subject in which they are to examine, in any university or college in the state accredited by the North Central Association of Colleges and Secondary Schools. No member may be engaged in the practice of the healing art or any branch thereof.

### CONNECTICUT

**Bills Introduced.**—S. 909 proposes to levy an annual tax on doctors of medicine, dentists, opticians, optometrists, oculists, and chiropodists equal to \$5 for each thousand dollars of gross income. H. 1041 proposes to create seven designated men as a body politic and incorporated by the name of The College of Natureopathic Physicians. The object of the corporation is to be instruction in the principles, practice and theory of natureopathy. The corporation is to have the right to establish and maintain hospitals, infirmaries and clinics. H. 1447 proposes to prohibit the retail sale of barbitol or any hypnotic or somnifacient drug except on the written prescription of a licensed physician, dentist or veterinarian. The term "other hypnotic or somnifacient drug" is to include trional, sulfonal, tetralol, paraldehyde, chloral or chloral hydrate and chlorbutanol. S. 1111 and H. 1444, to amend the medical practice act, proposes that "the use of the roentgen or x-ray or of radium in any manner for the treatment of any person shall be deemed to constitute the practice of medicine and surgery." H. 1442, to amend the chiropractic practice act, proposes that a licensed chiropractor "may practice chiropractic and prescribe hygienic and sanitary measures, but shall not prescribe for or administer to any person any medicine or drug included in materia medica or perform any surgery or practice obstetrics or osteopathy." H. 1449, to amend the chiropractic practice act, proposes (1) to increase the annual renewal fee charged chiropractors to \$5 and (2) to make the annual renewal of a chiropractor's license contingent on the presentation of satis-

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Jan. 30, 1937.

#### The Surgical Treatment of Cardiac Ischemia

At the Royal College of Surgeons, before a large audience, Laurence F. O'Shaughnessy delivered a special lecture on his new operation of cardio-omentopexy for the treatment of cardiac ischemia. Lord Dawson, president of the Royal College of Physicians, gave an introductory address. He was the head of a small cardiovascular clinic established at Lambeth Hospital by the London County Council, at which the medical staff cooperated with Mr. O'Shaughnessy. In cases in which coronary occlusion was not immediately fatal, the problem was to secure an adequate compensatory circulation. The difficulty was not in the anastomosis but in the great vascular needs of the heart. It was known that pericardial adhesions could form an effective collateral circulation. In one case it was found at necropsy that there had been complete occlusion of each coronary artery for a considerable time; yet there was no clinical history of an attack of thrombosis. The pericardial adhesions had actually been supplying the heart. Such a compensatory circulation through the pericardium might sometimes form by itself; but, if not, surgical measures were a reasonable procedure. The prospect should be good in selected cases, provided the capillary bed was not too degenerate to profit by the new arterial supply.

Mr. O'Shaughnessy referred to previous experiments on coronary occlusion in animals which showed survival after ligation of a main trunk and to experiments on animals performed in America by Beck and Tichy and reported in 1935, in which grafts from the pericardium, omentum and chest wall were applied to the heart. His own experiments on cardiac grafting began in December 1933. He used the omentum, which was the only structure in the body with the specific property of vascularization, a fact appreciated many years ago by Rutherford Morison in the operation of omentopexy for cirrhosis of the liver. The operation of cardio-omentopexy was performed on a grayhound in which the descending branch of the left coronary artery had been ligated. The animal could chase an "electric hare" around the full course without distress. Later the animal was killed and the vascular connections between the heart and the omentum were demonstrated. Major operations on the chest were justifiable only by close collaboration between physician and surgeon. It was not sufficient for a physician to refer a case; he must be in close contact with the patient in the immediate preoperative period and he must share the conduct of the postoperative period. In cardio-omentopexy he made, under general anesthesia with oxygen under pressure and vaporized ether, an incision along the fifth intercostal space from the midline to the anterior axillary line. The fifth and sixth intercostal cartilages were divided near the sternum and the pericardium was exposed by the use of a large Sauerbruch intercostal retractor. The phrenic nerve was identified and crushed with a hemostat. The left leaf of the diaphragm appeared in the operation field and, after the insertion of two sutures, the muscle was incised. The abdomen was then exposed through the diaphragmatic incision. A suitable portion of omentum was brought into the chest. The pericardium was cautiously incised and the graft attached to the heart and edges of the pericardium by sutures of fine linen thread. For the operation oxygen under positive pressure was necessary, so that transpleural exploration of the heart might be accomplished without disturbance. Surgical shock was eliminated in the first place by skilful anesthesia and secondly by the application of work on traumatic shock done at the college

by O'Shaughnessy and Slome in 1935. They showed that only two factors were concerned in shock-fluid loss at the time of the trauma and nervous impulses from the traumatized area, transmitted for some considerable time afterward. The approach in cardio-omentopexy was almost bloodless. The blocking of the phrenic nerve prevented the carrying of injurious impulses.

Mr. O'Shaughnessy briefly described five cases of angina pectoris or coronary thrombosis in which he had performed cardio-omentopexy and a sixth in which he assisted Mr. G. A. Mason. Reports would be published later. In none was there any anxiety during the operation or in the postoperative period. One patient died seven days after operation from hemorrhage from a chronic duodenal ulcer, but there was no postoperative disturbance and the blood pressure was 130. Two patients left the hospital in good condition. A fourth, aged 72, had a period of relief from angina and was able to go home but succumbed later to uremia. A fifth, who had been bedridden for eighteen months, was able to get up and walk. The sixth had left the hospital.

#### "A Coronary Survival Club"

In a letter to the *British Medical Journal*, Prof. Grey Turner has made an ingenious suggestion which arose out of a conversation after a dinner given at the Royal College of Surgeons. Among the specimens shown was a cat's heart to which omentum had been stitched to supply an additional circulation after ligation of the coronary artery by Mr. L. F. O'Shaughnessy. This specimen elicited great interest, especially among those present who had themselves been subjects of coronary mischief. It occurred to Professor Turner that there would be a brilliant opportunity for further research if those who had suffered from this malady, and in some respect had recovered so far as to enjoy a degree of their normal activity, would constitute themselves a "Coronary Survival Club." They might record their symptoms and send a provisional report to be cared for by the conservator at the college, at the same time arranging that on their demise the results of a necropsy should be recorded and sent to the same place. Much valuable information would thus be accumulated and might help to settle problems still unsolved. The discussion after the dinner showed that the factors concerned in coronary disease are uncertain and ill understood. A great example of the suggested procedure is furnished by the case of John Hunter, who recorded his symptoms and on whose body a necropsy was made by his brother-in-law, Everard Home.

#### Shortage of Radium

The National Radium Trust was established in 1929 with a capital of \$1,250,000, contributed by the public to provide radium for the treatment of disease. The trust appointed a national radium commission to distribute the radium to hospitals and clinics. In the report for the year ended July 1936, just published, the commission states that in order to secure efficient radium service for the country it will be necessary for the present radium centers to extend their work, new centers will have to be formed, and further supplies of radium are required. At most of the centers there has been a tendency to replace the interstitial and intracavitary use of small quantities of radium by the application at a distance of large quantities of radium. This method has led to many of the centers pressing the commission for more radium. The report records much progress at almost all the centers and high level of initiative and zeal, which will go far toward solving the grave problem of the commission. The trend of present-day experience indicates the advantages in certain cases of cancer of combining radium and x-ray treatment. It is calculated that in this country about 40,000 persons are suffering from cancer in those accessible organs in which radium may be of value, but that only 8,000 obtain the treatment.

## LOUISIANA

**Dr. Taquino Appointed Head of Department.**—Dr. George J. Taquino, professor of clinical otorhinolaryngology, Louisiana State University Medical Center, has been appointed professor and head of the department of otorhinolaryngology. A graduate of Tulane University of Louisiana School of Medicine in 1911, Dr. Taquino has been connected with the medical center since its establishment in 1931.

**First Graduate Medical Assembly.**—The first New Orleans Graduate Medical Assembly will be held in the Roosevelt Hotel, New Orleans, March 8-11, with Dr. Hyder F. Brewster as general chairman. The following speakers, among others, will be presented:

- Dr. John A. Kolmer, Philadelphia, Immunity and Vaccination Against Infantile Paralysis.
- Dr. George M. Piersol, Philadelphia, Value of Laboratory Studies in the Management of Nephritis.
- Dr. Lewis J. Pollock, Chicago, Physiology of Referred Visceral Pain.
- Dr. Hugh Trout, Roanoke, Va., Cancer of the Breast.
- Dr. Henricus J. Stander, New York, Cardiac Disease and Pregnancy.
- Dr. Clifford B. Walker, Los Angeles, Retinal Detachment and Its Relation to General Medicine and Surgery.
- Dr. Robert B. Osgood, Boston, The Anatomical and Physiological Causes of Low Back Pain; Diagnosis and Treatment.
- Dr. Meredith F. Campbell, New York, Urinary Infections in Children.
- Dr. George Gray Ward, New York, Complications of Cancer Therapy in Gynecology.
- Dr. Ralph M. Waters, Madison, Wis., Development of a Science of Anesthesia.
- Dr. Abernethy Benson Cannon, New York, Treatment of Vascular Anomalies of the Skin.
- Dr. Albert C. Furstenberg, Ann Arbor, Mich., Medical Treatment of Ménière's Symptom Complex.
- Dr. Anthony Bassler, New York, Hepatic Insufficiencies in Relation to Biliary Disorders.
- Dr. Russell L. Cecil, New York, Serum Therapy of Lobar Pneumonia With Special Reference to Some of the Newer Types.
- Dr. Rolla E. Dyer, Washington, D. C., Typhus.
- Dr. William W. Babcock, Philadelphia, Common Errors in Clinical Surgery.
- Dr. Julius Hess, Chicago, Present Status of Serum Therapy.
- Dr. Eugene P. Pendergrass, Philadelphia, Silicosis.

## MAINE

**Bills Introduced.**—S. 276 proposes to require all applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination and licensure by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology, pathology and hygiene, to be given by a board of examiners in the basic sciences, none of whose members can be licensed to practice the healing art. H. 1113 proposes to amend the state pure food and drug act as to include "cosmetics" within the act. The bill proposes to define cosmetics "to include all substances and preparations intended for external use in cleansing, altering the appearance, or promoting the attractiveness of the person, except that such term shall not include water or soaps represented for shaving or for cleansing purposes only." A cosmetic is to be deemed to be adulterated "if it bears any poisonous or deleterious substance or any harmful metallic salt in such quantity as may render it dangerous to the user under the conditions of use prescribed in the labeling thereof, or under such conditions of use as are customary or usual." A cosmetic is to be deemed to be misbranded if it is dangerous to health under the conditions of use prescribed in the labeling or advertising thereof, or if it fails to bear a statement of the name and address of the manufacturer, or producer, or seller, or distributor.

## MARYLAND

**Bills Introduced.**—H. 170 proposes to create a state board of naturopathic examiners and to regulate the practice of naturopathy. The bill provides that "Naturopathy and Natureopathy shall be construed as synonymous terms and are hereby defined to mean the use and practice of Psychological, Mechanical and Material health sciences to aid in purifying, cleansing and normalizing human tissues for the preservation or restoration of health according to the fundamental principles of anatomy, physiology and applied psychology, as may be required. Naturopathic practice employs, among other agencies, Phytotherapy, Dietetics, Psychotherapy, Suggesto-therapy, Aone-therapy, Bio-Chemistry, External Applications, Electro-therapy, Mechano-therapy, mechanical and electrical appliances, hygiene, first aid, sanitation and Heliotherapy." Nothing in the act is to be construed to permit a naturopath "to practice Materia Medica or Surgery or Chiropractic." H. 190, to amend the law prohibiting the retail sale and distribution of barbitol and other hypnotic and somnifacient drugs except on the prescription of a licensed physician, dentist, or veterinarian, proposes that nothing in the act shall be deemed to prohibit the administering or dispensing of barbitol or other hypnotic or somni-

ficient drugs in good faith, by duly licensed physicians, dentists or veterinarians to bona fide patients. The bill also proposes to make any violation of the act a misdemeanor punishable by a fine of not more than \$100 for each offense.

## MASSACHUSETTS

**Dr. Miner Awarded Medal.**—Dr. Leroy M. S. Miner, professor of clinical oral surgery and dean of Harvard University Dental School, Boston, was presented with the Achievement Award Medal of the Alpha Omega dental fraternity at a recent dinner. The medal is to be awarded annually for outstanding service in the field of dentistry. Dr. Miner is president of the American Dental Association and has made several contributions to the literature on his specialty. In 1904 he received the degree of doctor of medical dentistry from Harvard and in 1907 the degree of doctor of medicine from Boston University School of Medicine, where he is at present professor of stomatology. Speakers at the dinner included William Rich, D.D.S., New York, chairman of the award committee, who made the presentation address, and Howard M. Marjerison, D.M.D., dean of Tufts College Dental School, Boston.

## MICHIGAN

**Reuben L. Kahn Honored.**—Reuben L. Kahn, D.Sc., since 1928 director of laboratories, University Hospital, and assistant professor of bacteriology, University of Michigan Medical School, Ann Arbor, was recently presented with a gold medal by the Phi Lambda Kappa fraternity for his research work in tissue immunity. The presentation took place at the annual meeting of the fraternity in Detroit. Dr. Edward A. Stern, Detroit, received the national director's gold key for "outstanding work as chairman" of the convention.

**Tularemia in Detroit.**—Eleven cases of tularemia have been reported in Detroit this winter, according to *Detroit Medical News*. For the most part, the patients became ill in a few days after dressing rabbits. Seven patients were employed in meat markets, and two were housewives who purchased the dressed rabbits for food. All the patients admitted having a skin injury on the hand at the time of infection. Up to January 30 there had been no fatalities. The markets where the rabbits were secured were widely distributed. Apparently the rabbits were bought from wholesalers who received shipments from western states.

**Secretaries' Conference.**—The annual conference of county secretaries was held in Lansing, February 7, under the chairmanship of Dr. Louis Fernald Foster, Bay City. The speakers included Drs. Henry E. Perry, Newberry, and Henry Cook, Flint, president and president-elect, respectively, of the state medical society, and Paul R. Urmston, Bay City. The formal program was presented by the following:

- Dr. Perry, What the 1937 Legislature Holds for the Private Practitioner of Medicine.
- Dr. Grover C. Penberthy, Detroit, Scientific Aspects of Medical Practice Today.
- Dr. William W. Bauer, Chicago, Director, Bureau of Health and Public Instruction, American Medical Association, What a Good County Secretary Means to His Society.
- William J. Burns, Lansing, executive secretary of the state society, Leadership by the Physician and by His County Medical Society.

## MINNESOTA

**Bills Introduced.**—S. 611, to supplement the workmen's compensation act, proposes to make pneumoconiosis a compensable occupational disease, and to define pneumoconiosis as "a disease due to breathing air containing dust either organic or inorganic." H. 752 proposes to prohibit the retail sale and distribution of devices, appliances, or medicinal agents used in the prevention of venereal disease except by licensed pharmacists and by licensed physicians and surgeons.

## MISSOURI

**Bill Introduced.**—S. 76 proposes to grant to hospitals, treating persons injured through the negligence of others, liens on all claims, rights of action, judgments, or compromises accruing to the injured persons by reason of their injuries.

## MONTANA

**Bill Introduced.**—H. 59, to amend the workmen's compensation act, proposes to make occupational diseases arising out of and in the course of an employment compensable. The bill is so worded, however, as to make it probable that the only occupational diseases made compensable are silicosis and poisoning by lead, mercury, zinc, arsenic or phosphorus.

sanitary control of milk production. At the close of the meeting a committee was appointed to urge the passage of such a law.

### Cure of Pulmonary Abscess by Nonoperative Treatment

At the November 10 meeting of the Académie de médecine a report of seventy-two cases of abscess of the lung was read by Bezançon, Azoulay and Bernal. All cases in which tubercle bacilli were found in the expectoration, as well as cases that were evidently secondary to a bronchiectasis, were excluded. Of the seventy-two patients, ten died, nine passed into the chronic stage of suppuration and fifty-two (72 per cent) were cured following nonoperative (medical) treatment. The degree of the fetid character of the expectoration served as a basis in making a prognosis. Ninety-three per cent of the abscesses were of this character and the authors believe that the prognosis is good even though the abscess gives rise to a fetid expectoration. The etiology of the abscess is of no aid in making a prognosis. The same is true of the clinical picture. Multiple as well as solitary foci are included in the cured cases. Even though the general condition indicates a severe degree of toxemia, the outlook may be favorable. The results of the examination of the expectoration are of little help from a practical point of view. It was found that even in an abscess with putrid sputum, the case cannot be regarded as a more serious one than in those with nonfetid contents which are the result of ordinary pyogenic infection. In fact, at the present time the most valuable information is obtained by inspection of x-ray films. Every clinician agrees that the localization of the abscess with the aid of iodized oil is the most important diagnostic procedure. This preparation, when insufflated into the bronchi, does not infect an abscess. In the most common form of pulmonary abscess the bronchi are seen to be slightly dilated in the adjacent portions of the lung. In chronic gangrene, one can observe how the insufflation of iodized oil reveals a double process of death of tissue and a destructive sclerosis, which can take place early in the formation of the gangrenous area. In other cases a marked dilatation of the bronchi in the form of cavities arranged like a bunch of grapes is striking. The great value of insufflation with iodized oil as a diagnostic procedure from the beginning of the abscess formation was particularly emphasized, because it reveals the extent of the bronchiectases which make medical treatment almost impossible and are a disastrous complication from the surgical point of view. The roentgenographic study of a case permits one to understand and to determine in advance the variations in development of an abscess by means of the differences to be seen in the local anatomic changes. In cases of solitary circumscribed abscess formation, the evolution is usually uncomplicated, so that most of these heal under medical treatment. Cortical abscesses are the only exceptions to this rule. On the other hand, if there is pyosclerosis, i. e., much fibrous induration around the abscess, which is not frequent, spontaneous recovery is less certain, because there is a tendency for the condition to become more chronic, so that the extent of the lesions and diffusion of the tissue changes are the dominant factors in prognosis. The only cases in which early operation is indicated are those in which the abscess is a cortical one, i. e., near the pleural surface, and those with perforation into the pleural cavity. In the pyoscleroses, a lobectomy appears to be a logical procedure, but in spite of the rapid advances in pulmonary surgery, this operation must still be regarded as serious. Nearly all the patients with multiple abscess have recovered under medical treatment of various kinds, none of which seem to be specific.

In the discussion of this paper, Professor Sergent said that he had always emphasized the possibility of spontaneous recovery, but nevertheless one must always be on the lookout for

cases of apparent, i. e., pseudo, cure. An abscess that is either primarily or secondarily of a putrid character and becomes chronic gives rise to a progressively extensive chronic pneumopathy, which becomes sclerotic and ulceronecrotic. It is in such an area that bronchiectases form, and the result is a bronchiectatic pulmonary abscess. If operative intervention is delayed until this stage is reached, the patient is of course a bad risk for a lobectomy. If too much reliance is not placed on spontaneous recovery by medical treatment or in various methods of drainage, the chances of cure by pneumotomy or by partial cuneiform pneumonectomy would be far more favorable than if one waits too long. Sergent differed from the opinion of Bezançon in trying medical treatment first, because he has more confidence that operation will cure a larger percentage of cases. Professor Lemierre agreed with Professor Bezançon that the appearance and the examination of the expectoration might lead to false conclusions as to the character of a pulmonary abscess. He believes, however, that there is an important difference between an abscess due to ordinary pyogenic bacteria and one due to the bacteria found in a putrid abscess. Spontaneous recovery rarely occurs in the latter group of cases. Professor Debré, based on his experience with children, agreed with the authors of the paper as to the comparative rarity of gangrenous abscesses. Those due to the ordinary pyogenic bacteria usually heal spontaneously.

### Search for Tubercle Bacilli by Cultures of Feces

At the Oct. 27, 1936, meeting of the Académie de médecine Professor Bezançon and two associates, Braun and Aveline, reported the results of their trial of the culture method in the search for tubercle bacilli in the stools. Cultures of the sputum have rendered invaluable service in cases in which repeated examination by the staining method was negative. The Petragani-Loewenstein culture method for tubercle bacilli as developed by Saenz of the Pasteur Institute requires some modifications before it can be used in examination of the stools, according to Bezançon and his associates, who investigated the stools of 231 adults and children. This number included positive and suspected cases of pulmonary tuberculosis as well as normal individuals. Cultures made from the stools of 105 normal adults and twenty-three normal children were all negative. In fifty-seven cases diagnosed clinically as pulmonary tuberculosis, positive results were obtained in all the patients. In six of these it had been impossible to find the bacilli by any other method. In certain cases there are so few bacilli to be found that only a few colonies appear on fifteen or twenty inoculated tubes. In only two cases were paratuberculosis bacilli found, the colonies being chromogenic and avirulent. Whenever the laboratory and clinical observations disagree, it is advisable to check the culture method by guinea-pig inoculation of the colonies obtained on the culture medium.

### New Associate Fellows of Academy of Medicine

At one of the recent meetings of the leading medical society of France, the Académie de médecine, Prof. Ernest Malvoz of Belgium and Sir St. Clair Thomson of England were elected foreign associate fellows. The former is an eminent bacteriologist and has rendered valuable services in establishing anti-tuberculosis centers. Dr. Thomson has made some important contributions to the literature of his special field, otorhinolaryngology.

### Prof. Antoine Béchère Made Commander of Legion of Honor

The Legion of Honor was founded by Napoleon I as an order in which especially meritorious services can receive recognition by the government. The lowest rank is Chevalier, then Officer, and the highest rank is Commander. The last named title has just been bestowed on Dr. Antoine Béchère.

per cent of all deaths. Diabetes, cancer and diseases of the heart, kidneys and arteries and cerebral hemorrhage all showed considerable increases. New York's automobile death rate was 12.6; there has been a steady decline since 1929, when the rate was 19.7. The rate from other accidents was 44 per hundred thousand. Suicides, which reached a high point of 1,595 deaths, a rate of 22.5 in 1932, dropped to 1,087, a rate of 14.8. The birth rate in 1936 was 13.4, having declined to that point from 19.6 in 1927.

#### NORTH DAKOTA

**Bills Introduced.**—H. 193 proposes that in all cases in which any public board is required by law to provide the assistance of a physician to indigent persons, such assistance shall be furnished by a medical doctor, osteopath or a chiropractor as requested by the indigent person. H. 288 proposes to authorize counties to levy a tax not exceeding 6 mills on every taxable dollar of property within the county for the purpose of providing a fund to pay for medical, surgical and hospital care to be rendered all residents of the county. Apparently residents will be permitted to choose physicians, chiropractors and osteopaths of their own choice and to determine the hospital in which they desire hospitalization. The county in turn will pay practitioners and hospitals for care rendered to residents according to a schedule of fees set out in the bill. H. 291 prohibits the sale and distribution of adulterated and misbranded cosmetics. The bill defines cosmetics as "all substances and preparations intended for cleaning or altering the appearance of or promoting the attractiveness of the person except that such term shall not include soaps represented for cleansing purposes only." H. 355, to amend the medical practice act, proposes that "the giving of treatment by baths, massage, therapeutic light rays, natural sun rays or the teaching or the cure of disease by the use of exercise, diet, manner of living or religious rights" shall not be deemed to be the practice of medicine.

#### OHIO

**Bills Introduced.**—S. 132 proposes to establish an independent board of osteopathic examination and registration to consist of five osteopaths, to examine and license applicants to practice osteopathy and surgery "in accordance with the principles as taught in recognized colleges of osteopathy and surgery." No osteopath holding a license to practice osteopathy at the time of the passage of the bill is to be permitted to practice major surgery, which is defined to mean the performance of those surgical operations attended by mortality by the use of the knife or other surgical instruments, until he shall have passed an examination in surgery to be given by the board, but he may practice minor and orthopedic surgery. Applicants for licenses to practice osteopathy and surgery must have a high school education, have attended a recognized college or university two years or more receiving credits for sixty or more semester hours and have a diploma from a reputable school of osteopathy in good standing. S. 204 proposes to authorize municipal hospitals to enter into contracts with insurance companies, service associations or companies, employers of three or more employees, fraternal organizations and other persons or groups of persons, to provide specified hospital care to persons insured, or subscribers for hospital service, employees, members or persons covered by such contracts. H. 210, to amend the law providing that the state insurance laws shall not be construed to apply to hospitals furnishing care by virtue of any contract made with residents of the county in which the hospital is located, proposes to extend the exemption to such contracts made by hospitals "with any resident of this state or with any person employed in this state." H. 172 proposes to create an independent board of chiropractic examiners to consist of three chiropractors, appointed by the governor from a list of names submitted by the Ohio state chiropractic society, and to regulate the practice of chiropractic. The bill defines chiropractic as "the art and science of locating, the procedure preparatory to adjusting, and the adjusting by hand of the subluxations of the articulations of the human spinal column, which is deemed to be the twenty-four movable vertebrae, including the sacrum and coccyx and adjacent tissues, for the purpose of removing any interference with nerve transmission; but it shall not include major surgery, nor the administration or prescription of any drug or medicine included in materia medica." The bill further proposes that "nothing herein contained shall be construed as limiting a licensee in the use of any non-therapeutic procedure generally used by any healing profession either in making a proper analysis and diagnosis, or having such made by any accepted public agency or laboratory."

#### OKLAHOMA

**Syphilis Control Committee.**—The president of the Oklahoma State Medical Association, Dr. George R. Osborn, Tulsa, has appointed the following committee to assist in the syphilis control program now being sponsored by the U. S. Public Health Service: Drs. David V. Hudson, Tulsa, chairman; Shade D. Neely, Muskogee, and Robert H. Akin, Oklahoma City.

#### OREGON

**Alumni Meeting.**—Dr. Karl A. Menninger, Topeka, Kan., will be the guest speaker at the twenty-fifth annual meeting of the Alumni Association of the University of Oregon Medical School in Portland, March 8-10. This is the fiftieth anniversary of the medical school. Details may be obtained from Dr. Thomas D. Robertson, St. Vincent's Hospital, Portland.

**Bills Introduced.**—S. 279 proposes to amend the law so as to require, as a condition precedent to the issue of a marriage license, the presentation of a physician's certificate, showing that both parties to the proposed marriage are free from contagious or infectious venereal diseases, epilepsy, feeble-mindedness, insanity, drug addiction, and chronic alcoholism. The law now requires a certificate from the groom alone showing that he is free from contagious or infectious venereal disease. S. 301 proposes that "in all actions for damages for personal injuries resulting from the use of x-ray, radium, violet ray, artificial heat, permanent wave machines, and from all other electrical and mechanical devices and apparatus, in the treatment of persons, and which are under the exclusive control of the person administering such treatment, proof of injury shall constitute prima facie evidence of negligence." H. 281 proposes to authorize corporations, contracting to furnish medicine, medical or surgical treatment, nursing, hospital service, ambulance service or dental service, to transact a hospital association business. The bill also proposes to authorize physicians and surgeons to contract, contingent on sickness or injury, to perform their own professional services, but not to permit them to agree to furnish in addition to their own services, hospital care, nursing or dental service unless they comply with the hospital association business law. H. 283 proposes to authorize employers to contract with their employees to provide them with medical and surgical care and treatment, nursing and hospital service contingent on sickness or injury and to retain a portion of their wages for that purpose. The bill contemplates that the employer in turn shall enter into agreements with any association or corporation to supply the necessary medical, surgical and hospital care and attention to their employees. The bill proposes to make it unlawful for any employer to retain, directly or indirectly, any part of the money collected for his own use or benefit.

#### PENNSYLVANIA

**Personal.**—Dr. Herbert C. Woolley, Washington, D. C., has been appointed superintendent of Pennhurst State School for mental defectives, to succeed Dr. Walter R. Krauss, resigned. —Dr. Wilbur E. Turner, Montgomery, was honored by a testimonial dinner given by the Montgomery Rotary Club, January 15, in recognition of his election to the presidency of the Lycoming County Medical Society.

#### Philadelphia

**Physicians' Aid Association.**—Dr. John M. Fisher was reelected president of the Aid Association of the Philadelphia County Medical Society at its recent annual meeting, and Dr. Henry P. Brown Jr., secretary-treasurer. In his annual report Dr. Fisher said that the funds of the association had been taxed far beyond their capacity to do more than mitigate the distress of its dependents. Receipts during the year diminished and the number applying for aid increased, Dr. Fisher said. The committee on benevolence distributed \$5,078.11 to eleven annuitants receiving regular amounts and twenty-five beneficiaries receiving varying amounts for emergencies.

**Joint Surgical Meeting.**—The Boston Surgical Society met jointly with the Philadelphia Academy of Surgery, February 15. The morning was devoted to a group of case reports presented at University Hospital. In the afternoon the following program was presented at the auditorium of the College of Physicians of Philadelphia:

Dr. Isidor S. Ravdin, Nutritional Edema.

Dr. Arthur Bruce Gill, Dupuytren's Contracture.

Dr. Lewis K. Ferguson, Treatment of Filonidal Cysts by Delayed

Excision and Primary Suture in Ambulatory Patients.

Dr. George Wagoner, Haverford, Chronic Sciatic Pain Due to

Adhesions About the Nerve Trunk and the Results of Their Removal

by Operation.

Dr. Thomas A. Shallow, Esophageal Diverticula.

Dr. Joseph C. Birdsall, The Relationship of Hydronephrosis to

Nephrophtosis.

Of the occupational diseases, severe pneumoconiosis was most prevalent among miners and industrial workers in earth and stone. Lead poisoning was most frequent in the metallurgic industries. Cases of infection that could be classed as occupational disease cases were more common among workers in the public health and welfare services and in maritime navigation. The quarry workers' organization reported a decline in the number of cases of occupational disease: in 1934 there were 182 cases; in 1935, 148 cases; in the same period the number of newly compensated cases sank from seventy-three to forty-three and the number of fatalities from thirty to twelve. The campaign against pneumoconiosis receives substantial support in the transactions published by the Antidust Center, which was founded in 1935 as an adjunct of the occupational organization. Originally, provision was made for group examinations of various gangs of endangered workers with a portable x-ray apparatus but this procedure was never actually followed and instead the specialist examined the workers in their home towns, using the local apparatus.

In the metal industry, 2,127 cases of occupational disease were reported during 1935 compared with 2,147 in 1934; there were 104 newly compensated cases in 1935 compared with 124 in 1934, and thirteen fatalities in 1935 compared with twenty-four in 1934. Lead poisoning, carbon monoxide poisoning, skin diseases, pneumoconiosis and so on appeared chiefly to be traceable to ground basic slag.

The printing industry reported 223 cases of occupational disease in 1935 (249 in 1934). Attempts to devise a photo-engraving technic that will in no way injure the worker's health have not been successful.

The professional association for public health and welfare service reported an increase in the number of cases from 556 in 1934 to 703 in 1935; of the latter, fifty-nine cases were incorrectly recorded. In 1935 there were ninety-eight newly compensated cases (1934, ninety), of which eighteen were fatal (1934, nine). This increase in illness was due to a prevalence of mild cases of infectious disease among institutional workers. There was an increase in the number of intoxications from x-rays and other types of radiant energy and from arsenic. On the increase also were cases of diphtheria, scarlet fever, influenza, sore throat, syphilis, pulmonary tuberculosis, erysipelas, whooping cough, measles, furunculosis, gonorrhea and brucellosis. Fewer cases were reported of poisonings from lead, mercury, carbon disulfide and carbon monoxide, chronic recurrent skin diseases, typhoid, lupus, varicella, granulosis and paratyphoid.

## VIENNA

(From Our Regular Correspondent)

Jan. 2, 1937.

### The Sixth International Congress of Urology

The series of medical conventions held at Vienna during September was brought to a close by the Congress of the Internationale Gesellschaft für Urologie. This international society is a small organization, its membership being limited to the leading urologists of various countries. Only papers on well defined and significant topics were submitted at the Vienna convention. The Spanish delegates were unable to attend because of the civil war at home; their discussions were read by Dr. Hryntschak.

The first topic, carcinoma of the prostate, was discussed by Drs. Hryntschak and Bauer. The most important finding from their extensive research is the possibility of an inflammatory etiology of prostatic cancer. Further, it has been demonstrated that in a certain number of cases of prostatic hypertrophy a carcinomatous alteration is present but without clinical grounds for suspicion. Of 310 cases in which prostatectomy was performed, 3 per cent showed the presence of a carcinomatous

alteration without on the whole there being clinically any suggestive manifestation; in a good 7 per cent the histologic picture exhibited modifications that were considered as precancerous.

Dr. C. A. R. Nitch of London discussed the conservative treatment of carcinoma of the prostate. This includes radiotherapy, surgical therapy and combinations of the two methods. Roentgen therapy produces good results at first; the end results are disappointing whether the Holfelder method or the Lewitt intensive irradiation is used. The results are more favorable with radium if the prostate is approached from all sides. The author applies 70 mg. of radium; that is, 14 mg. to the posterolateral surfaces, 50 mg. from the side of the bladder and 5 mg. from the side of the urethra. He estimates the number of cases cured at 28 per cent. The conservative surgical treatment (suprapubic drainage, electrosection) can be introduced only in carefully selected cases; the last named method should in future, in conjunction with radium, become the method of choice.

A discussion by Oreja of San Sebastian had to be read by a proxy, owing to circumstances already mentioned. Oreja emphasizes that an exact and timely diagnosis is of fundamental prognostic importance. The common adenomatous hypertrophy is frequently related to incipient malignancy; thus the presence of this condition is a valuable diagnostic indication of early stage carcinoma. Careful rectal palpation is mandatory in men over the age of 50 who complain of urinary disturbances.

In surgical treatment both the perineal and the suprapubic approaches are used. A majority of surgeons prefer the perineal approach, although a suprapubic prostatectomy is no more difficult. Optimal results are obtained if the prostate is only in a suggestive condition or if the carcinoma is first discovered in the course of the intervention. If, however, an unequivocal diagnosis has been established, radical intervention is not promising. Transurethral resection has had of late more advocates than suprapubic cystostomy and the results of the former appear to be more favorable. With increased experimentation it should shortly become the method of choice.

A discussion of blood stream infection of the kidney was submitted by Cabot of Rochester, Minn. In a group of forty-six patients presenting acute inflammatory processes in the nose, mouth and ear and in which the urine was apparently normal, the presence of bacteria could be detected microscopically in thirty-two cases and culturally in eighteen cases. It was thus demonstrated that in such cases the pyogenic cocci are soon present in the urine; they usually disappear, however, after a short time. The lesions are found in the medullary substance and the cortex of the kidney. Pyelography is an important diagnostic aid. In peracute cases treatment is purely surgical. In cases presenting chills, high fever and leukocytosis but without essential urinary changes, nonsurgical treatment is often advantageous. For a third category, the subacute cases with less turbulent courses, conservative treatment is indicated. But if a perinephric abscess has developed, surgical intervention must be undertaken. The fourth group is composed of borderline cases, which frequently represent the sequels of disturbances in the upper respiratory tract. The symptoms are slight but the cocci are always present in the urine. In such cases operation has scarcely ever to be considered. Varied types of operation are indicated somewhat as follows: nephrectomy in peracute cases, nephrectomy in cases presenting disseminated foci of infection without massive formation of abscesses; if massive abscesses are present, decapsulation and drainage should be performed. In many cases the perinephric abscess is laid bare and the extent of the disease is estimated on the basis of the process disclosed.

Professor Illyes of Budapest and Dr. Necker of Vienna discussed suppuration in the renal parenchyma. The Hungarian

cedent to the issuance of licenses to marry, that both parties to a proposed marriage shall present "a certificate of health issued and certified by a registered practicing physician, dated for not more than five days prior to application of certificate of marriage, showing that the contracting parties are free from venereal diseases which have been acquired and not of an inherited nature." H. 242 proposes, as a condition precedent to the issuance of a marriage license, to require both parties to proposed marriages to submit a certificate from a licensed physician that neither party has any venereal or other infectious or communicable disease.

### WISCONSIN

**Bills Introduced.**—S. 86 proposes to provide a penalty for any person "who shall refuse to permit any duly licensed physician or surgeon to employ the available facilities and rooms of any hospital at the usual rates of charge of such hospital for such facilities and rooms, and attend and work for his patients therein and to render therein his professional services as a physician or surgeon." S. 100 proposes that (1) if a person afflicted with tuberculosis fails to comply with the regulations of the state board of health, he may be committed to a state tuberculosis hospital or to a county tuberculosis sanatorium which can provide proper care and (2) to authorize the local health officer to quarantine any person with tuberculosis who persistently continues to violate the rules and regulations of the state board of health. S. 88 proposes to require a physician knowing or having reason to know that a person treated or visited by him has poliomyelitis to report the facts to the local health officer and to the state board of health.

### WYOMING

**Bill Passed.**—H. 177 has passed the house, proposing to repeal present laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

**Bills Introduced.**—H. 265 proposes to prohibit the retail sale and distribution of appliances, drugs, or medicinal preparations intended or having special utility for the prevention of venereal diseases, except by persons licensed to do so by the state board of health or by licensed physicians, chiropractors or osteopaths. H. 276, to amend that section of the medical practice act stating what persons shall be regarded as practicing medicine, proposes, in effect, that a person holding himself out to the public as being engaged in the diagnosis and treatment of diseases or injuries or deformities of human beings shall be regarded as practicing medicine only if he utilizes medicine and surgery in his therapy.

### GENERAL

**Physical Therapy Meeting.**—A sectional meeting of the American Congress of Physical Therapy will be held in St. Louis March 9 in the auditorium of the St. Louis Medical Society. Among the speakers will be Drs. William H. Schmidt, Philadelphia, on "Evaluation of Fever Therapy After Six Years' Experience"; Miland E. Knapp, Minneapolis, "Ultra-violet Treatment of Erysipelas"; Frank H. Krusen, Rochester, Minn., "Physical Therapy in Fibrositis," and Albert F. Tyler, Omaha, "X-Ray Treatment of Acute and Chronic Infections." Mr. Howard Carter, B.S. in M.E., secretary of the Council on Physical Therapy of the American Medical Association, Chicago, will give a demonstration of "Physical Aspects of Short Wave Diathermy."

**Surgical Congress at Charlotte Instead of Louisville.**—The annual assembly of the Southeastern Surgical Congress will be held in Charlotte, N. C., instead of Louisville, Ky., March 8-10. The change was made because of flood conditions in Louisville. Among the speakers will be Drs. Charles Gordon Heyd, New York, President, and John H. J. Upham, Columbus, President-Elect of the American Medical Association; William Wayne Babcock, Philadelphia; Edward D. Churchill, Boston; Winchell McK. Craig, Rochester, Minn.; George W. Crile, Cleveland; Louis G. Herrmann, Cincinnati; Arthur E. Hertzler, Halstead, Kan.; Herman L. Kretschmer, Chicago; Dean D. Lewis, Baltimore; George H. Semken, New York. At a public meeting Dr. William D. Haggard, Nashville, Tenn., will deliver the first C. Jeff Miller Memorial Lecture. Dr. John Darrington, Yazoo, Miss., is president and Dr. Fred W. Rankin, Lexington, Ky., is president-elect of the congress. Further information may be obtained from the secretary, Dr. Benjamin T. Beasley, 701 Hurt Building, Atlanta, Ga.

**Centennial Edition of Dispensatory.**—The twenty-second edition of the U. S. Dispensatory, called the "centennial edition," has come from the press. The first edition of this encyclopedia of drugs used in the United States, Canada and Great Britain was published in 1833 under the editorship of George B. Wood, great-uncle of the present editor, Horatio C. Wood, Philadelphia. The first volume contained 1,073 pages and listed 4,800 titles; the new one has 1,894 pages and 28,000 titles. More than 300,000 copies have been sold to pharmacists all over the world in the last 100 years. The present edition was eight years in preparation. Dr. Wood is professor of pharmacology and therapeutics at the University of Pennsylvania, professor of pharmacology in the Philadelphia College of Pharmacy and Science and a member of the Committee on Revision of the U. S. Pharmacopeia. Associated with him on the editorial staff is Charles H. LaWall, Pharm.D., professor of pharmacy, Philadelphia College of Pharmacy and Science, and also a member of the revision committee. Other members of the editorial board are Heber W. Youngman, Ph.D., of the Massachusetts College of Pharmacy, Boston; Arthur Osol, Ph.D.; Ivor Griffith, Ph.M., and Louis Gershenfeld, Pharm.M., all of the Philadelphia College of Pharmacy and Science.

**Medical Bills in Congress.**—*Changes in Status:* H. J. Res. 229 has passed the House and Senate, proposing to authorize the President to allocate to the U. S. Public Health Service funds from appropriations available for emergency relief for health and sanitation activities in the flood stricken areas. S. 655 has been reported to the Senate, proposing to add the name of Dr. Roger P. Ames to those honored by the act recognizing the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever. *Bills Introduced:* S. 1567, introduced by Representative Sheppard, Texas, and H. R. 4415, introduced (by request) by Representative Hill, Alabama, propose, among other things, to permit the Bureau of Mines to sell to citizens of the United States or to corporations, under regulations approved by the President, any helium that is produced in plants operated by the government or under lease or contract with it for the production of helium, that is not needed for government use. H. R. 4798, introduced by Representative Maverick, Texas, proposes to provide vocational guidance, vocational training, and employment opportunities for youths between the ages of 16 and 25 years. Any young person employed under the act, if injured during the course of employment, is to receive "all necessary medical expenses." H. R. 4808, introduced by Representative Izac, California, proposes to provide pensions for former enlisted men of the Army, Navy or Marine Corps who have heretofore separated or who may hereafter separate from the service with a disability incurred or aggravated in line of duty of such a nature and extent as to disqualify for further military or naval service. H. R. 4843, introduced by Representative Hobbs, Alabama, proposes to repeal the emergency officers' retirement act. H. R. 4857, introduced by Representative Lanzetta, New York, proposes to authorize the Administrator of Veterans' Affairs to furnish domiciliary, medical and hospital care to veterans residing outside of the continental limits of the United States or its Territories, or possessions, if such veterans are citizens of the United States and are suffering from disabilities due to service in the armed forces of the United States. S. 1629, introduced by Senator Walsh, Massachusetts, proposes to regulate traffic in surgical ligatures and sutures. The bill proposes that surgical ligatures and sutures, to be salable in the District of Columbia, or in interstate and foreign commerce, must be prepared at an establishment holding an unsuspended and unrevoked license issued by the Secretary of the Treasury and that the container must be plainly marked with the proper name of the article, the name, address, and license number of the manufacturer, and the date beyond which the contents cannot be expected beyond reasonable doubt to yield their specific results.

## Government Services

### Physicians Wanted for the Conservation Corps

The Medford, Oregon, district of the Civilian Conservation Corps, is in need of physicians. The salary is \$225 a month. Applicants must have licenses to practice. Those interested are asked to wire the District Surgeon, Medford CCC District, Medford, Ore.

## Deaths

**Elias Hudson Bartley**, Brooklyn; Long Island College Hospital, Brooklyn, 1879; member of the House of Delegates of the American Medical Association, 1909-1910; member of the Medical Society of the State of New York; past president of the Medical Society of the County of Kings and the Associated Physicians of Long Island; fellow and formerly vice president of the American College of Physicians; since 1917 emeritus professor of chemistry and pediatrics at his alma mater, dean and professor of pediatrics, 1915-1917, professor of chemistry, toxicology and pediatrics, 1901-1915, professor of chemistry and toxicology, 1886-1901, and instructor of chemistry, 1880-1886; dean and professor of organic chemistry at the Brooklyn College of Pharmacy, 1892-1902; chief chemist for the health department of Brooklyn, 1882-1888; member of the Kings County Board of Pharmacy, 1892-1898; consulting pediatrician to the Long Island College Hospital, Methodist Hospital and the Kingston Avenue Hospital, Brooklyn, where he was also president of the medical board for many years, and the Southside Hospital, Bayshore; had been chief of the department of pediatrics at the Brownsville and East New York Hospital; member of the U. S. Pharmacopeia conventions in 1890, 1900, 1910 and 1930; author of "Textbook on Medical and Pharmaceutical Chemistry," which went through seven editions from 1885 to 1909, and of "Manual of Clinical Chemistry," through three editions; aged 87; died, January 12, of senility.

**Luther Fiske Warren** • Brooklyn; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; professor of medicine, Long Island College of Medicine; past president of the Medical Society of the County of Kings; member of the New York State Board of Medical Examiners; regent and fellow of the American College of Physicians; member of the Association for the Study of Internal Secretions, Congress of Internal Medicine, American Association for the Advancement of Science, National Tuberculosis Association and various others; physician in chief to the Long Island College and St. John's hospitals; medical director of the Brooklyn Home for Consumptives, consulting physician to the Methodist Episcopal and Lutheran hospitals, Brooklyn, Southside Hospital, Bayshore and the Brunswick General Hospital, Amityville; member of the board of trustees of the Polytechnic Institute and the Packer Collegiate Institute; chairman of the public health committee and member of the board of directors of the Brooklyn Chamber of Commerce; formerly president of the Brooklyn Health Council; aged 51; died, January 18, of carcinoma, secondary to carcinoma of the breast.

**Marshall Morgan Cloud** • Captain, U. S. Army, retired, Los Angeles; Kansas City (Mo.) Medical College, 1892; assistant superintendent of the Kansas State Hospital, Topeka, 1893-1895; was appointed a first lieutenant and assistant surgeon in the medical corps of the U. S. Army in 1896, veteran of the Spanish-American War and was retired for disability in line of duty with rank of captain in 1901; on active duty during the World War; fellow of the American College of Surgeons; clinical professor of ophthalmology at the University of Southern California School of Medicine, 1910-1913, and professor of military medicine, 1920-1923; ophthalmologist to the National Soldiers Home, Sawtelle, Calif., 1910-1913, and the Santa Fe Railway, 1910-1921; was examining surgeon for the U. S. Pension Bureau; on the staffs of the Hollywood and Los Angeles General hospitals; author of "Guide to the Chemical Analysis of Water and the Sanitary Analysis of Water," 1905; aged 68; died, Dec. 3, 1936, of amebic dysentery.

**Robert Battey Greenough** • Boston; Harvard University Medical School, Boston, 1896; formerly assistant professor of surgery at his alma mater and the graduate school; past president of the Massachusetts Medical Society; fellow and past president of the American College of Surgeons; member of the American Surgical Association, Society of Clinical Surgery, New England Surgical Society, New England Roentgen Ray Society and the American Radium Society; president and member of the board of directors of the American Society for the Control of Cancer; served during the World War; was a medical inspector in the U. S. Naval Reserve Force; consulting surgeon to the Massachusetts General and the Collis P. Huntington Memorial hospitals; for several years chairman of the Harvard Cancer Commission; aged 65; died, February 16, of arteriosclerosis with coronary occlusion.

**Collins Hickey Johnston** • Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; member of the House of Delegates of the American Medical Association in 1908; fellow of the American College

of Physicians; member of the American Clinical and Climatological Association; for many years chairman of the Kert County Medical Milk Commission; member of the medical advisory board during the World War; formerly member of the board of education and board of health; was surgeon for the Grand Trunk and New York Central Railroad; member of the visiting staff of the Blodgett Memorial and Butterworth hospitals; honorary chief of staff of the D. A. Blodgett Home for Children; aged 77; died, Dec. 29, 1936, of coronary thrombosis and arteriosclerosis.

**Francis Dennis Donoghue** • Boston; Harvard University Medical School, Boston, 1894; for many years instructor in surgery at the Tufts College Medical School; surgeon to the Boston Dispensary and consulting surgeon to the Jordan Hospital, Plymouth, Mass.; in 1912 was appointed medical adviser to the Massachusetts Industrial Accident Board; in 1925 was appointed by the President to represent the United States at the International Conference on Accidents at Amsterdam, was a delegate to all succeeding congresses and was permanent vice president from the United States and a member of the council; aged 65; died, January 4, in the Peter Bent Brigham Hospital, of secondary anemia and complications.

**Dorian Feigenbaum** • New York; Medizinische Fakultät der Universität Wien, Austria, 1914; member of the American Psychoanalytic Association, American Psychiatric Association and the American Psychopathological Association; formerly instructor in neurology at the Columbia University College of Physicians and Surgeons; was medical director of the Hospital for Mental Diseases of Jerusalem; consultant in criminal lunacy to the government of Palestine, 1921-1923; had been an assistant in neurology at the Vanderbilt Clinic, 1931; founder and editor-in-chief of the *Psychoanalytic Quarterly*; aged 49; died, January 2, of pneumonia.

**Frank Caulkins Bunn** • Orange, N. J.; New York Homeopathic Medical College and Hospital, 1889; fellow of the American College of Surgeons; member of the medical advisory board during the World War; a founder, senior surgeon and member of the board of trustees of the Homeopathic Hospital of Essex County, East Orange; consulting surgeon to St. Mary's Hospital, Passaic, Fitkin Memorial Hospital, Neptune, Essex County Hospital for Contagious Diseases, Belleville, Montclair (N. J.) Community Hospital and the Presbyterian Hospital, Newark; aged 68; died, January 9, of coronary disease.

**Fred Gershom Fielding** • Glens Falls, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; member of the American Academy of Ophthalmology and Oto-Laryngology; past president of the Warren County Medical Society; formerly member and president of the board of education; member of the board of managers and vice president of the Westmount Sanatorium; a member of the consultant staff and at one time president of the attending staff of the Glens Falls Hospital; aged 70; died, January 9, of chronic myocarditis.

**Joseph Edward Fuld**, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; member of the Medical Society of the State of New York; was appointed assistant visiting surgeon at the City Hospital in 1912, in 1925 was elected visiting surgeon, and since 1935 consulting surgeon; formerly on the staff of the Gouverneur Hospital, visiting surgeon of the division of surgery and gynecology at the Correction Hospital; aged 64; died, January 3.

**Urban Grant Iles**, Orlando, Fla.; Rush Medical College, Chicago, 1888; in 1920 was appointed medical examiner by the Bureau of War Risk Insurance, and after serving on several boards of appeals was assigned to the Veterans Administration Hospital, Augusta, Ga.; aged 72; died, Dec. 21, 1936, in the Orange General Hospital of coronary sclerosis, pernicious anemia and arteriosclerosis.

**Jean Albini Aubry**, Rochester, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1928; member of the Medical Society of the State of New York; instructor in obstetrics and gynecology at the University of Rochester School of Medicine and Dentistry; on the staff of the Strong Memorial Hospital; aged 35; died, Dec. 20, 1936, of subacute bacterial endocarditis.

**Charles De Lancey Alton** • Hartford, Conn.; Bellevue Hospital Medical College, New York, 1875; member of the American Clinical and Climatological Association; past president of the Hartford County Medical Society; medical referee for the Connecticut Mutual Life Insurance Company; aged 91; died, January 8, of arteriosclerosis and auricular fibrillation.

**George Albion Dickson**, Ogden, Utah; Bellevue Hospital Medical College, New York, 1891; member of the Utah State Medical Association; formerly city councilman and member

**Sir Grafton Elliot Smith**

Sir Grafton Elliot Smith, the anatomist and anthropologist, has died at the age of 65. Born at Grafton, New South Wales, of English and Welsh stock, he was educated at the University of Sydney, graduating M.B., Ch.M. in 1892. In 1900 he was appointed the first professor of anatomy at the new Cairo Medical School, established by the government. He supervised the examination of the skeletal remains of 30,000 Egyptian burials, predynastic and dynastic, and also examined mummies. He next studied the history and pathology of the ancient Egyptians and the process of mummification. The results were "The Ancient Egyptians," published in 1911, which was received with enthusiasm by many anthropologists, and "The Royal Mummies," published in 1921, which threw a new light on Egyptian history. He deduced the intrusion of a new racial element (Armenoid) into ancient Egypt.

In 1909 he was appointed professor of anatomy at Manchester University and in 1919 professor at University College, London. He introduced the cranial cast for the study of the brain of early man—a method that has been pronounced probably his greatest contribution to human paleontology. His work on human paleontology was embodied in "The Evolution of Man," published in 1924. He expounded the importance of the "Peking man," discovered by his friend the late Davidson Black.

His peculiar distinction was that he was preeminent both as a physical and as a cultural anthropologist. His studies led him to formulate the theory that all civilization originated in Egypt, whence it spread all over the world. He took the lead in exposing the Aryan and Nordic myths. At the University College he reorganized the department of anatomy with the aid of a grant from the Rockefeller trustees. He planned it so that the study of man's evolution and physical structure should proceed side by side with the study of the development of culture. His plans were brought to fruition by the appointment in 1927 of a co-worker, W. J. Perry, as reader in cultural anthropology.

**Transmission of the Human Influenza Virus**

At the Nov. 24, 1936, meeting of the Académie de médecine the results of experiments on the transmission of the virus of human influenza to ferrets were reported by de la Rivière and Cheve. They have confirmed the work of British and American investigators who showed that ferrets can be infected either with the rhinopharyngeal mucus of human beings suffering from influenza or from ferrets previously inoculated. The contamination follows either in an indirect manner by placing infected ferrets in cages in which there are noninfected ferrets, or directly by intranasal instillation or intrapulmonary inoculation of the nasopharyngeal secretion of influenza patients. The animals show marked symptoms of influenza, such as oculonasal catarrh, sneezing, a diphasic temperature curve, somnolence and anorexia. These symptoms recede rapidly and the animal recovers in the majority of cases. The virus can be transmitted to a series of ferrets and even to mice. The latter can be infected only following ether anesthesia and only with a virus derived from an infected ferret. Mice cannot be infected directly by the human virus. The disease in ferrets is contagious for human beings, as has been shown in England and the United States. The virus is a filtrable one, which passes through a 12 Chamberland filter as well as collodion filters. Both human beings and animals that have been infected by the ferret virus show marked immunity for a certain length of time.

**Tuberculous Meningitis from Unboiled Cow's Milk**

A paper which adds another link in the chain of evidence that unboiled milk from tuberculous cows can result in tuberculous meningitis in children was read by Lesne, Saenz, Salembiez

and Costil at the Nov. 17, 1936, meeting of the Académie de médecine of Paris. The rôle of the bovine bacillus in the etiology of tuberculous meningitis has been studied but little in France, so that a complete review of the experience in other countries was first given. During the past four years the authors studied bacteriologically the cerebrospinal fluid in 138 cases of meningitis in the children's service of Lesne at the Trousseau hospital. None of these children had been given the BCG vaccine. In only eight cases was a negative result obtained. The clinical evolution of these eight cases showed that the meningeal syndromes were nontuberculous and curable (secondary meningeal reactions or serous benign meningitis).

The use of the Loewenstein culture medium as modified by Saenz showed that it was the best which is available at present, for detection of tubercle bacilli in the cerebrospinal fluid, because inspection of the colonies on the inoculated medium, before inoculation of rabbits is done, enables the bacteriologist to distinguish the bovine and human types of tubercle bacilli. Every specimen of the cerebrospinal fluid was inoculated on from six to eight tubes and placed in an incubator at 37 C.

Of the 130 cases thus studied, 121 showed, in the cultures, tubercle bacilli of the human and nine of the bovine type. The date of appearance of the colonies in the case of the human type varied from eleven to twenty-nine days, whereas those of the bovine type appeared later, from thirty to seventy-two days. The number of colonies of the human were far more numerous than those of the bovine type. Inoculation into rabbits of the colonies from the nine patients in whom the bovine type was found confirmed the cultural evidence that the bacilli were of this type. It is a well established fact that the guinea-pig is not susceptible to the bovine type of tubercle bacillus, whereas the rabbit is.

Seven of the nine children in whom the bovine type was found were less than 5 years of age, and eight of the nine had been given unboiled milk during most of their life. Nearly all of the nine children had been raised in country districts, not a single one having ever lived in Paris. In five of the nine cases, familial contamination could be excluded. In the other four, no information as to this point could be obtained. In the ninth case, although the father had suffered from a pulmonary tuberculosis, the child had been given only unboiled milk.

This occurrence of tuberculous meningitis of the bovine type in children who had been given only unboiled milk is in striking contrast to the 121 cases in which the human type was found in the cerebrospinal fluid. Of these 121 patients (human type), 50.61 per cent lived in Paris, 25.70 per cent in the suburbs and only 10 per cent in country districts. In almost all, inter-human contagion was found as the etiologic factor. All of these 121 children were raised on pasteurized or boiled milk.

These studies prove that unboiled milk is the source of infection in children who have tuberculous meningitis of the bovine type. It has been shown that the milk of cows with tuberculous mastitis is a common source of infection. As high as 100,000 virulent bacilli per cubic centimeter have been found in such milk. Other sources of infection of milk are found in soiling of the udders by stable dust or excreta. Gosio of Milan reported that, in a single farm, out of 107 samples of milk examined, sixteen were found to contain tubercle bacilli. Sixteen of these 107 samples were obtained from animals in which no effort had been made to cleanse the udders. On another farm, where such precautions were constantly taken, only one cow of fifty-six had infected milk.

In the discussion Martel maintained that, in spite of the progress in surveillance of cows with and without evident tuberculous lesions, some tuberculous cows are sold because there is no law in France which renders possible an obligatory

### FACTORS IN THE GROWTH AND IDENTIFICATION OF THE GONOCOCCUS

To the Editor:—I have read with interest in Current Comment (THE JOURNAL, Nov. 7, 1936, p. 1564) the paragraph entitled "Cultural Methods for the Diagnosis of Gonococcal Infections." In the course of several years' study I have had an opportunity to compare the various mediums recommended for the growth of the gonococcus. Included in two papers (Proc. Soc. Exper. Biol. & Med. 31:899 [May] 1934 and J. Infect. Dis. 55:328 [Nov.-Dec.] 1934) is the description of what proved a most efficient medium. This was a modification of Hitchen's semisolid agar, which differs from the standard mediums in that it contains potassium nitrate (0.2 per cent) instead of sodium chloride (0.5 per cent). Enrichment fluids were added to the medium used for plating and these included whole blood, egg yolk, serum and transudates, each with good result. However, ascitic fluid was found more practical since it was easily obtained, could be filtered through a Berkefeld filter to guarantee sterility, and, since it rendered the medium transparent, proved very desirable for colony study. Autoclaved peptones were used in both the semisolid and the solid agar mediums and, contrary to the results of McLeod and his associates, no inhibitory effect was noted.

There are a number of factors about the growth of the gonococcus which are learned by experience and often by trial and error methods. For instance, freshly poured agar plates and the presence of sufficient moisture in the incubator are important to initial growth. If plated directly, dilution of the pus in a few cubic centimeters of physiologic solution of sodium chloride before streaking may mean a positive culture on the one hand, while failure to do so will often result in a negative culture.

Decreased oxygen tension or the addition of 10 per cent carbon dioxide to the atmosphere in which the gonococcus is grown stimulates the growth, it is true, but this is true not only for the gonococcus but for other organisms as well, so that often the separation is made more difficult. The same purpose is served by the maintenance of a proper incubator humidity.

I have tried the "oxydase test" of Gordon and McLeod and have found it helpful in some instances, but when other organisms also take the dye one is again confronted with the task of picking and staining from a plate which is swimming in dye and the whole flora is more or less confluent. Of course, isolation and subculture are made more difficult in the latter event.

My methods of isolation and growth are described in the papers mentioned. I prefer to inoculate the infectious material directly into test tubes containing semisolid medium, staining by Gram's method after incubation of from eighteen to twenty-four hours, then subculturing to ascitic fluid agar plates and finally identifying the colony types within the next twenty-four to forty-eight hours. If preferred, the infectious material may be diluted in a few cubic centimeters of physiologic solution of sodium chloride and planted directly on freshly poured ascitic agar plates. Instances are encountered in which the growth is sluggish and appears as a faint haze in semisolid agar (and negative when planted directly on solid medium); when stained by Gram's method, the culture may show gram-negative particles, which are suggestive but not definite in morphology. These cultures should not be discarded but transplanted to fresh medium and watched carefully. Several transplants in series will be often rewarded by a culture which finally shows typical forms of the gonococcus.

Absolute identification should not only include fermentation tests, dye tests and Gram's staining, which are all presumptive evidence, but also agglutination or complement fixation, with the use of a number of type specific antisera.

The problem of identification in chronic cases must be left in the hands of experienced workers. Although bacterial dissociation of the gonococcus is not yet universally accepted, it has nevertheless proved that the gonococcus may change in morphology, staining and biochemical reactions. This knowledge has shown how hazardous it is to dismiss a patient as cured when he may harbor these changed forms of the gonococcus which under proper conditions, either in the same or on transfer to a new host, may reactivate or initiate an acute manifestation of the gonorrheal infection.

CLARA RAVEN, Chicago.

Resident in Pathology, Cook County Hospital.

### "LIVER DEATH A HEPATORENAL SYNDROME"

To the Editor:—Your editorial entitled "Liver Death a Hepatorenal Syndrome" (THE JOURNAL, January 23, p. 301) directs attention to a very important subject. The discussion following the mention of the three groups is confined largely to the second and third groups, in which death is due to uremia rather than to cholemia and in which a substitution of the term "hepatorenal syndrome" for "liver death" would tend to diminish confusion. In view of the fact that in group 1 death follows not only cholecystectomy but likewise cholecystostomy and other operations not related to the biliary tract, and that it also occurs under certain circumstances without an antecedent operation, the matter of "trauma to the liver" would seem to be a comparatively unimportant factor, with relationship of the liver quite uncertain. Therefore the descriptive term "rapid high temperature death" might very well replace that of "liver death" until more exact information regarding its cause (probably cerebral) has been determined.

FRANK GREGORY CONNELL, M.D., Oshkosh, Wis.

### EUTHANASIA

To the Editor:—An article in the New York Herald Tribune for Sunday, January 17, has just been brought to my attention. It is entitled "Mercy Deaths for 'Incurables' Opposed by 54 per cent in Nation Poll, but Physicians Approve by 53 per cent." This attributes to me, in a survey made by the American Institute of Public Opinion, the following statement:

Sentimental prejudice should not stand in the way of civilization. It is my opinion that not only incurables, but kidnapers, murderers, habitual criminals of all kinds, as well as the hopelessly insane, should be quietly and painlessly disposed of.

Inasmuch as the following paragraph states that you "take violent exception to this point of view," I wish to inform you that I have never advocated the killing of incurables, although quotations of this sort have been attributed to me several times. In my book "Man, the Unknown," on pages 318-319, I wrote:

Those who have murdered, robbed while armed with automatic pistol or machine gun, kidnaped children, despoiled the poor of their savings, misled the public in important matters, should be humanely and efficiently disposed of in small euthanasic institutions supplied with proper gases. A similar treatment could be advantageously applied to the organic guilty of criminal acts. Modern society should not hesitate to organize itself with reference to the normal individual. Philosophical systems and sentimental prejudices must give way before such a necessity. The development of human personality is the ultimate purpose of civilization.

This is the only statement on the subject of euthanasia that I have ever made. When asked on different occasions for my opinion on "mercy killings of incurables," I have referred the inquirer to this exact reference in my book.

ALEXIS CARREL, M.D.,  
Rockefeller Institute for Medical Research, New York.

the internationally known radiologist, who is still active at the age of 80 years. Dr. Bécère is an ex-president of the Académie de médecine and is an emeritus attending radiologist in the public hospital service of Paris.

#### Annual Election of the Academy of Surgery

The leading surgical society in France, the Académie de chirurgie de Paris, has chosen as officers for 1937 Dr. Baumgartner as president and Dr. Chevassu as vice president. The London surgeons G. E. Gask and G. G. Turner were elected associate foreign members.

#### The German National Health Bureau

The National Health Bureau, which recently celebrated its sixtieth anniversary, has undergone reorganization within recent years. Ten years ago, at the time of its fifty-year jubilee, the bureau was divided into four sections: the human-medical, the veterinary medical, the food and chemical and the biologic-bacteriologic-zoological. At that time the staff comprised, in addition to the president and the four sectional directors, sixty-one scientific officials and employees, among whom were twenty-five physicians, eighteen chemists and three pharmacists. As Dr. Schütt, the director of a section, states in "Der öffentliche Gesundheitsdienst": The basic acceptance of the National Socialist weltanschauung necessitated a tremendous expansion of public health activities and this called for drastic changes in the organization of the bureau.

In place of the former four sections there are now twelve sections. Section A, the human-medical section, has remained essentially the same and is now as before the foundation of the bureau. It is a clearing house for statistical data on a diversity of subject matter: nationwide campaigns against disease, antituberculosis, anticancer, antivenereal; vaccination legislation, reforms in the curriculums of medical schools, new regulation of roentgen and radium irradiation, affairs of organizations such as the associations of hospitals, of midwives, of watering places and of health stations; problems of maternity, infant and child welfare, dental supervision in the schools and so on. Special circumstances have necessitated the creation of a separate bureau on abuses in the field of medicine.

Section B is devoted to all aspects of veterinary medicine throughout the reich: antiepidemic campaigns and so on.

Section C, food and chemistry, deals with problems presented by trade in foodstuffs and so on. This section makes exhaustive studies of the bread problem. The National Commission for Research on Wine is also a part of section C.

Section D deals with sanitary problems of water supplies, drainage and housing. It no longer exists as a single section, for its functions have been assumed by the State Institute for Hygiene of the Water, Soil and Air, of which the president of the National Health Bureau is also a member.

Section E is the industrial hygiene section. It deals with all questions that relate to labor and the protection of the workers' health. By its merger with the former general hygiene section, new duties have accrued to section E. These have to do with various problems of sanitation and hygiene presented by municipalities, dwellings, rural settlement projects and also the problems of traffic safety and hygiene.

Section F deals with problems of pharmacology and physiology. It has undergone expansion through the creation of a special bureau for homeopathy. For the rest it functions in close collaboration with section G, the section on pharmaceutical substances and opium. The latter section deals with all the problems of pharmacy. The revision of the statutes governing pharmacy, which has been in progress for the past decade, has been among the duties of this section. A special subdivision

is the "opium center"; one of the newly established card catalogues of this department vouchsafes a surveillance of all the narcotics in the German reich.

Section H, which formerly concerned itself with experimental research in bacteriology and biology, has been merged with the Robert Koch Institute for Infectious Diseases.

Section I was formed from a biochemical subdivision of section H for the performance of certain special functions.

Section K is synonymous with the before mentioned Robert Koch Institute, which now confines its activities to the human-medical-bacteriologic sphere. The former section on veterinary medicine has been annexed to section B.

Section L, on eugenics and racial supervision, is a complete innovation, an outgrowth of the new official German ideology. It was set up in March 1935. Its principal objective is the organization of a genetic-biologic survey of the entire German population. The section itself serves as headquarters for this project. Already it has assembled more than a million catalogue cards. These are uniform for the entire reich and are at present undergoing scientific and statistical evaluation. Moreover, it is contemplated to introduce uniform criminologic-biologic investigations of all penal institutions and to initiate a survey of the psychopathic hospitals. Next will follow a study of the inmates of orphanages.

Section M, the section for genetic research, is likewise a new creation. Its aim is to study problems of public health policy while making ample use of scientific genetic experimentation with animals and plants. The attempt is being made to arrive through such experimentation at conclusions applicable to human biology. Various laboratories are given over to special fields of research, such as *Drosophila* genetics, genetic population research, fish genetics, protozoology, and experimental constitutional research.

Section N is concerned with the physiology of nutrition. It is also a new unit organized for the study of national food problems. This section maintains a laboratory for research on the physiology of nutrition. The German Society for Research on Nutrition and the National Cooperative Association for Nutrition collaborate closely with the work of section N (THE JOURNAL, May 5, 1934, p. 1510). The ultimate objective of this section is a domestic production of foodstuffs sufficient to sustain the entire nation.

The staff of the National Health Bureau comprises at present about 500 persons, 200 of whom are university trained. The personnel of the Robert Koch Institute for Infectious Diseases and of the National Institute for Hygiene of the Water, Soil and Air are included in these figures. The bureau is under the ministry of the interior but because of its manifold functions it is also affiliated with other ministries. Among the current publications of the bureau are "Reichs-Gesundheitsblatt," "Arbeiten aus dem Reichsgesundheitsamt" and more recently "Schriftenreihe des Reichsgesundheitsamt" and the journal *Die Ernährung*.

#### The Increase in Occupational Diseases

The increase of around 22 per cent in the number of full time employees, which took place in 1934, was paralleled by an increase of around 7 per cent in the number of reported cases of occupational disease. But the number of such cases in which compensation was granted for the first time in that year showed a decrease of 17 per cent compared with 1933. In 1935 the number of full time workers underwent a further increase of 10 per cent: from 9,450,000 in 1934 to 10,430,000 in 1935. The number of reported cases of occupational disease increased 12.2 per cent in 1935 compared with the preceding year; there were 7,664 cases in 1934 and, according to tentative computation, 8,601 in 1935. Newly compensated cases increased by a mere 0.7 per cent: 1,043 cases in 1934, 1,125 cases in 1935.

doses of the alkyl nitrates, aminophylline, bismuth subnitrate 0.65 Gm. three times a day or intramuscular magnesium sulfate may be tried. (See Stieglitz, *Abnormal Arterial Tension*, New York, National Medical Book Company, 1935.) Sodium thiocyanate is a dangerous drug in inexperienced hands and in the presence of renal impairment is contraindicated. The only safe method of using thiocyanate clinically is that of Barker (*THE JOURNAL*, March 7, 1936, p. 762), which involves frequent determination of the blood and urine thiocyanate content to warn of retention of the drug. The last principle of therapy, which is often grossly neglected, includes energetic attempts at correcting anemia, which is commonly present in hypertensive disease, and in insuring adequate nutrition.

#### EFFECTS OF ALUM IN DIABETES

*To the Editor:*—A woman, aged 52, had markedly severe diabetes some years ago and with diet now has only infrequent symptoms. She can make herself sugar free if and when she does adhere to a more or less restricted diet. Like all patients with diabetes, she likes to go on a spree once in a while. To get to the point in question, however, she tells me that for a number of years she has been able without dieting much, if any, after one of these sprees to cause her urine to test sugar free and to feel much better by taking a solution of ordinary alum; i. e., 4 teaspoonfuls of water and one teaspoonful of powdered alum, taking one teaspoonful in half a glass of milk from three to four times daily. This, she says, will make her urine "clear" in about three days to one week, being "red" at the start. Can you tell me the pharmacology and possibly the physiologic reason for this? I have not tested her urine before and after this medication, as she is a thoroughly reliable person. Needless to say, blood sugar tests are done infrequently here and I have not done them. I thought that possibly the alum might have an action on the kidneys to raise the threshold for sugar. However, it seems to me that if that were true her blood sugar would rise and she would feel worse instead of better. Please omit name.

M.D., Michigan.

**ANSWER.**—We have been unable to find any reference in the scientific literature to the use of alum in the treatment of diabetes.

If, as suggested, the alum raises the kidney threshold for sugar, simultaneous blood and urine sugar determinations at that time would reveal this effect.

This patient can render herself sugar free after a spree by following a restricted diet. A more probable explanation of the effect of alum may therefore be that this strongly astringent material interferes with the absorption of foodstuffs from the gastro-intestinal tract and is therefore equivalent to a dietary restriction.

#### KINGSBURY-CLARK METHOD FOR ALBUMIN IN URINE

*To the Editor:*—Recently I have had the opportunity of seeing described in several medical journals various methods for rapidly determining the presence of albumin in the urine. Though the Kingsbury-Clark method has been described previously I feel that it again should be called to the attention of the general profession, especially since the model C Clark lamp has been placed on the market. During the past ten months all the urinalyses made in the office laboratory have been done by this method, which include approximately 3,000 examinations. This lamp is so devised that it is possible, by an extremely simple procedure, to examine fifteen specimens within fifteen minutes and the results obtained are unusually accurate. The apparatus has been most beneficial for making urinalyses for insurance companies, in which a definite amount of albumin in 100 cc. of urine can be reported. This method is also most helpful when combined with a microscopic study of the urine in observing the progress of the various inflammatory conditions of the kidneys. The model C Clark lamp with instructions for the technic employed can be purchased from R. P. Cargille Company, 118 Liberty Street, New York, at a very reasonable cost.

CHESTER W. LONG, M.D., Milwaukee.

**ANSWER.**—The Kingsbury-Clark method for the determination of albumin in the urine was described by N. R. Blatherwick, Ph.D., in the *Journal-Lancet* 53:57 (Feb. 1) 1933. The article also included a technic for the Benedict picrate method for sugar determination in the urine.

This method is quantitative and therefore of great value in following the progress of renal disease. The test is based on the precipitation of albumin by sulfosalicylic acid. The amount of albumin is determined by comparing with a series of standards representing from 10 to 100 mg. of albumin per hundred cubic centimeters of urine. This comparison can be made by daylight or better still by using the model C Clark lamp, to be described.

The Kingsbury-Clark test is performed as follows: Pipette 2.5 cc. of centrifugated urine into a test tube graduated at 10 cc. and add 3 per cent sulfosalicylic acid to the 10 cc. mark. The sulfosalicylic acid solution is made by dissolving 30 Gm. and diluting to 1,000 cc. with distilled water. Invert the tube to mix and allow to stand ten minutes, and compare the tur-

bidity with the permanent turbidity standards. Record the value of the standard most closely matched as the albumin content of the urine. The standards are 10, 20, 30, 40, 50, 75 and 100 mg. of albumin per hundred cubic centimeters of urine. When more than 100 mg. is present the urine is diluted quantitatively and reexamined. A value of 50 mg. per hundred cubic centimeters corresponds to what is usually called a trace by the Heller nitric acid or heat and acetic acid tests. The standards should be replaced every nine months.

The model C Clark lamp was originated by Dr. Charles P. Clark of the Mutual Benefit Life Insurance Company. It has been used by life insurance and clinical laboratories since 1925. It provides a constant source of light which permits comparisons to be made independently of variations of natural daylight. It yields results of great accuracy. Differences of 0.001 per cent of albumin in the range 0 to 0.03 per cent of albumin are said to be detectable with this lamp. The tubes are lighted nephelometrically, but a black strip at the bottom of the rack enables the observer to make comparisons by transmitted light, or turbidimetrically. The lamp is also useful for observing minute traces of any precipitate, or insoluble or suspended matter.

The price of the Clark lamp, model C, is \$26.50. The set of eight standards costs \$7, and matched tubes graduated at 2.5 and 10 cc. are \$2 a dozen. These are supplied by the R. P. Cargille Company, 118 Liberty Street, New York.

#### SENSITIZATION DERMATITIS IN ASTHMATIC PATIENT

*To the Editor:*—I am 24 years old and for six years have had what has been diagnosed as chronic eczema, allergic eczema and neurodermatitis of the face, neck and scalp, and at various times on the antecubital and postpopliteal areas, the wrists and the groin. The eczema of the hand followed a severe impetigo for which ammoniated mercury was used. During the past two years I have been subject occasionally to asthmatic attacks. During these six years I have used various metallic and other ointments and also received a great variety of injections, both metallic and endocrine in nature. I also received x-ray and ultraviolet ray treatments. I have also experimented extensively with elimination diets and have spent several weeks in "allergen-free" rooms. None of these therapeutic efforts have been of any avail. About seven months ago, blurring of the vision led to the discovery of incipient bilateral cataracts, which have progressed rapidly until now reading is impossible. The opacities are located centrally near the posterior capsules of both lenses. I should like what information you can give me as to the etiology and prognosis of these cataracts. I have received different opinions from different sources, some saying that operation is inevitable and others telling me of cases in which the cataracts receded with a cure of the eczema. My next therapeutic effort will be a change of climate and I should like to know whether to relieve my eye symptoms before I do so. Could you also tell me how often these stubborn eczemas respond to changes of climate and are there any particular localities that you recommend? I thank you for any information you may give me and for any suggestions you may offer. I should appreciate a prompt reply, as my eye condition is progressing rapidly and I should like to make a decision. Please withhold name.

M.D., New York.

**ANSWER.**—The description is that of a sensitization dermatitis occurring in an allergic individual (asthma). This type of eczema is usually stubborn in its response to therapy, because of the multiplicity of factors that usually form the basis for the sensitivity. Nervous factors such as strain or exhaustion are profound contributors in the precipitation or aggravation of the attack.

The effect of climate on cases of this type is variable. Improvement is often noted after a change, but it is a question in some cases whether this improvement is due to a change of certain sensitizing factors in the old environment or is a result of the calm and relief of nervous tension usually obtained in new surroundings. The choice of a locality should be governed chiefly by previous experience with the effect of hot dry climates, or of moisture and dampness on the asthma.

Although mention is made of numerous intelligent therapeutic measures, together with elimination diets, there is no comment regarding skin tests. Investigation by scratch, intradermal or patch test methods for possible sensitivity to foods, pollens, bacterial proteins and animal epidermals should be instituted to see whether any information can be gained from these sources regarding precipitating factors for the asthma and eczema. Such information would be of value also in the selection of suitable regions to accomplish a beneficial change of climate.

There is probably no direct relation of the lens opacities to the eczema, except as a possible associated defect of vulnerable ectodermal tissue. If there is definite injury of the lens fibers with opacities, this damage is permanent, and one cannot expect a restoration of these definitely damaged areas with clearing up of the eczema.

If the eye condition is making rapid progress, the decision of the attending ophthalmologist should be followed as to the

scholar divided the infections into urogenic or ascending, hematogenic or descending, and lymphogenic. In each type bacteria may enter the blood stream of the kidney and obstruct the vascular loops of the glomeruli. In urogenic infections the lower urinary passages have been for the most part already infected, and from this location the infection travels to the kidneys. The lymphogenic infection is only rarely demonstrable with certainty. It may develop in cases of appendicitis or suppurative adnexitis. The colon bacillus appears as the most frequent agent in renal abscess. Streptococci and staphylococci follow in the order named. Differentiated clinically are (1) suppurative nephritis, (2) suppurative pyelonephritis and (3) pyonephrosis or contracted kidney. The greater number of cases fall into the second group.

Illyes makes the following recommendations with regard to therapeutic measures: In the cases of group 1, nephrectomy for patients who are in poor general health and who have chills, pain and fever; otherwise decapsulation. In renal carbuncles, either nephrectomy or, if the carbuncle is more favorably situated, incision and drainage (open treatment). For the cases of group 2 in which the retention of urine plays the most important part (renal calculi, calculi in the ureters, prostatic hypertrophy, stricture, compressions) the conservation method is preferable, as the author has been persuaded after observation of 455 cases. Pyelitis gravidarum requires operation only infrequently (sixteen of 207 cases). For the cases of group 3, which represents the terminal form of the renal suppuration, diagnosis is not difficult and the therapy should, wherever possible, consist of radical operation, although the latter is frequently difficult and heroic. Only in the most urgent cases is nephrotomy to be performed.

Necker's discussion dealt with other aspects of the same topic: On the basis of animal experimentation and after observation of a large number of cases, Necker differentiates a primary and a secondary parenchymatous suppuration. Primary suppuration denotes a circumscribed disease process of the cortex of the kidney, produced by pyogenic cocci. There are present diffuse miliary abscesses and infarcts as well as large intrarenal abscesses. The cortex is always involved.

The secondary parenchymatous suppuration is usually a colon bacillus infection. Its development depends on dynamic factors in the excretory urinary passages. Predominant symptoms are fever and pain due to pressure in the renal region. The pathologic pictures are seldom typical, usually obscure. Diagnosis is in many instances difficult, since the temperature becomes normal from time to time and the changes in the urine are not always unequivocal. Of greater significance is the continuous observation of the hemogram and of the blood sedimentation rate. If the condition is detected early enough, a surgical intervention (incision, excochleation) will produce favorable results. Secondary parenchymatous suppuration frequently causes such damage to a kidney that the maintenance of the organ is rendered impossible, although in certain cases favorable results may still be obtained by removal of obstructions from the urinary tract. Prognosis is, however, at best none too good, as not infrequently both kidneys are affected.

Professor Rubritius of Vienna next discussed the physiology of the excretory urinary passages. The basis of his experimentation was the behavior of the muscular hollow organs. He pointed out the close relationship between the function of the particular zones of these muscular organs. One section acts as a detrusor, another as a sphincter; the entire hollow organ is, so to speak, split up into functional segments that are coupled together with one another. For example, while the bladder is contracted, the peristalsis of the upper urinary passage ceases. In addition, however, the mucous membranes of the urinary tract are not without function, as they are the

seat of resorption. The excretory urinary passages constitute a closed system, the individual parts of which work together hand in hand. Therein are to be found both muscular activity and resorption; the latter supplies important data for future investigations.

A final discussion was provided by Professor Snapper of Amsterdam on the pathologic physiology of urinary secretion. The urine is a functional result of the various, wholly disparate physiologic processes in the glomeruli and the tubules. In the glomeruli an ultrafiltrate is separated from the blood plasma and this exhibits all the crystalloids of the plasma in the same concentration as in the blood. The colloids (proteins) do not pass through the glomerulus membrane. In the canaliculi a resorption of water and of various substances takes place, however. Experimentation has demonstrated that in one minute's time the astonishingly large amount of from 110 to 170 cc. of glomerular filtrate may be secreted and that from 97 per cent to 99 per cent of this water is reabsorbed in the canaliculi. The level of the blood pressure is of essential importance for the glomerular function, and this means not only the pressure in the aorta but also the independent self-sustaining alterations of blood pressure in the glomerulus. For the protection of the renal parenchyma during the secretion of the acids, the formation of ammonia is of greater significance. For clinical diagnosis the different functional tests are of the greatest value; in particular the urea-clearance test, the phenolsulfonphthalein test, the creatinine test and the dilution-concentration test. The nonsecretory renal functions should also be considered: important syntheses (hippuric acid), oxidations (acetone bodies) and the formation of ammonia.

In addition to these principal discussions, a hundred other important communications were scheduled to be submitted; so the Austrian delegates, as hosts, waived the reading of their own papers. More than eighty foreign urologists were accordingly given time in which to present their contributions. In the open discussion, however, all the delegates participated in appropriate measure, each speaker being allowed the floor for only five or ten minutes.

There were also the customary social and official receptions and entertainments, as well as the tours of inspection of scientific institutions.

## Marriages

BENNETTE EDWARD STEPHENSON JR., Weldon, N. C., to Miss Alma Hazel McGee of Willow Springs in Raleigh, Dec. 26, 1936.

HENRY CLAY ROBERTSON JR., Charleston, S. C., to Miss Caroline Elizabeth Lebby of Washington, D. C., January 2.

GEORGE AUDNEY REYNOLDS, Bowling Green, Va., to Miss Pearle Maupin Young of Fredericksburg, Dec. 31, 1936.

BENJAMIN WHEELER JENKINS, Philadelphia, to Miss Mary Agnes Wills of Jenkintown, Pa., Dec. 30, 1936.

WALLACE BROWN BRADFORD, Charlotte, N. C., to Miss Margaret Godfrey of Ambler, Pa., January 8.

LLOYD L. THOMPSON, West Point, Neb., to Miss Betty Lou Tapscott in Greenfield, Ind., Dec. 29, 1936.

JOHN THOMAS ASSEY JR., Georgetown, S. C., to Miss Helen Louise Maguire of Charleston, January 5.

KUTCHEN T. KLEIN, Meridian, Miss., to Miss Thelma Weatherford of Decatur, Dec. 30, 1936.

GUSTAVUS A. RUSH JR., Meridian, Miss., to Miss Helen Virginia Arline of Atlanta, Ga., January 11.

ARTHUR DAVID BUSSEY, Two Rivers, Wis., to Miss Henrietta S. Heller of Milwaukee, Nov. 14, 1936.

PAUL K. CANDLER, Emory, Va., to Miss Leah Estelle Haynie of Reedville, Dec. 22, 1936.

DANIEL CATLIN to Miss Doris Havemeyer, both of New York, February 9.

## EDEMA OF ANKLES

To the Editor:—A man, aged 38, complains of swelling of both ankles and feet for the last fifteen years. He has been employed in a slaughterhouse for the past twenty-two years and has been handling hogs and hog meat constantly during this period. He works at least ten hours a day and is called on to perform duties in the smokehouse, where the temperature averages 100 F., and in the refrigerators, where the temperature averages 30 F., continually going from the one extreme to the other for short intervals. The family history is entirely negative; his past history is noteworthy because he states that he has had none of the childhood diseases. He had influenza in 1918, has occasional sore throats, and three years ago had "yellow jaundice" and vomiting, which was diagnosed by a physician as ptomaine poisoning. There is no history of cardiac, lobar, renal, circulatory, syphilitic or malignant states. His ankles began to swell about 1920, when they "puffed up considerably all of a sudden." They do not swell at all in winter but, as soon as warm weather begins, "puff up and hang that way." The swelling disappears completely during the night but begins immediately on arising and gradually grows more severe as the day progresses. The condition has become worse during the last four weeks, so that he is no longer able to tighten his shoes. The last four days, since the onset of the extremely warm weather, the swelling has not receded at all during the night. He is able to walk without any difficulty, though he is "very tired in his legs." Above his knees he feels perfectly well but below them he feels played out. Other contributing facts are that the bowels are constipated; purgatives are necessary but the medication has not been too severe and has varied. There are occasional frontal headaches, probably due to refractive error; he drinks from eighteen to twenty cups of coffee every day, sleeps well and is not nervous. He has no aches or pains and is in excellent health, excepting for the condition described. On examination he is apparently healthy, is well developed and nourished, and lies comfortably on his back. There is no cyanosis. The pupils react to light and in accommodation. There is a superficial grayish ulceration of the lower gum which the patient ascribes to irritation from his dental plate. There is no glandular enlargement. The lungs are clear on auscultation and there is no impairment on percussion. The heart sounds are clear and are regular in rate, force and rhythm. The abdomen is normal; there is no enlargement of the liver or tenderness over this region. The genitalia and rectum are normal. Both ankles and the dorsum of both feet are edematous; the skin is tense and shiny and pits deeply on pressure. There is no discoloration of the skin. However, there are numerous small crusted excoriated areas with an inflamed areola over both legs and feet. There are a few small blebs present and one large area where a large bleb ruptured. Complete laboratory work (blood and urine) is negative. The blood pressure is 130 systolic, 80 diastolic. Is this edema due to circulatory deficiency resulting from the long standing exposure to variable extremes in temperature? Is there any occupational disease that would account for the condition? Do you think that passive vascular exercise would be helpful? Please omit name.

M.D., Maryland.

ANSWER.—The edema described is suggestive of some impediment to the return venous flow. It is sometimes seen in those whose employment forces them to work for long periods in a standing position, and especially when associated with high room temperature. It is at first due to a decreased tone in the vessel walls, secondarily to the heat, and to the prolonged standing position. Later varicosities frequently develop. Other sources of mechanical obstruction to the return venous flow should be considered. The condition appears from the description to be of circulatory origin, but a lymphatic edema must be considered. Passive vascular exercise is not indicated in this case. Well fitting elastic stockings might be tried.

## ZINC OXIDE FUMES FROM EFFECTS OF ACETYLENE TORCH ON GALVANIZED IRON

To the Editor:—I am interested in knowing what type of fume or gas is given off in the process of cutting galvanized iron sheeting with an acetylene torch; also which of these gases are deleterious when inhaled in the process of cutting galvanized iron sheeting with an acetylene torch and without the use of any mask for protection. Do the fumes from ordinary tar when boiling, and inhaled in the course of work, entail any great danger? I should also like to be referred to any literature that I can investigate.

M.D., Ohio.

ANSWER.—The chief fume produced in the burning off of galvanizing with an acetylene torch is zinc oxide. This zinc oxide is likewise the chief disturbing agent for exposed workmen: The high temperature of an acetylene torch readily vaporizes galvanized coating. This operation, because of the high temperatures involved, constitutes one of the most ready causes of zinc "metal fume fever." In the trades this condition is widely known as "zinc chill," "zinc ague," "spelter chill," "brassfounders' ague," and so on. Remotely the possibility exists that other gases or fumes might arise from this operation. Lead may be present in small quantities as an impurity in the zinc. Carbon monoxide has been known to arise. Hydrogen sulfide has been found in acetylene gas. However, the presence of these other gases or fumes ordinarily may be disregarded as improbable. The practical hazard is from the zinc.

Ordinary coal tar, when boiling, emits vapors that may be somewhat irritating to the skin, conjunctivae and mucous membranes. So complex is the mixture of these vapors that significance may not be attached to any one agent. One case attributed to boiling tar was reported in THE JOURNAL, March 2, 1929, page 695. In view of the wide applications of hot tars and asphalts, both inside buildings and in the open, such as on road work, it would appear that proved ill effects are not well established.

## DINITROPHENOL—DELAYED HEALING OF WOUNDS

To the Editor:—In July 1934 a patient of mine took an advertised dinitrophenol product for one month. During this period she lost 15 pounds (13.6 Kg.). Thereafter she took no more of this preparation and soon regained the pounds that she had lost. In October 1935, a year and three months after the dinitrophenol episode, she was operated on by a surgeon for prolapse of the uterus. The usual midline incision was made. Following the operation the patient developed a "stitch abscess" and this was followed by complete nonunion and sloughing of the tissues of the abdominal wall. In spite of all the usual methods of combating such a problem, namely, the use of various antiseptic dressings, exposure to the air, light therapy, and so on, the process has been progressive. Recently there has been a breaking down of the tissues overlying the anterior spines of the ilia, with tunneling extending to the original site of incision. The laboratory work in this case has not been comprehensive, showing only the presence of staphylococcus organisms. There does not appear to be any evidence of actinomycosis, blastomycosis or other fungus disease. In summary it may be said that the abdominal wall tissue apparently have no resisting and healing properties and the question arises whether the dinitrophenol medication fifteen months before operation could be a factor in the lack of healing properties demonstrated at this time. I should appreciate some word as to whether the dinitrophenol could be a factor in the nonhealing of this wound. Please omit name.

M.D., Illinois.

ANSWER.—Dinitrophenol has no influence on the healing of wounds. Experimental attempts have been made to determine whether or not it might increase the speed of healing of incisions, but carefully controlled experiments showed that it had no effect whatever. Dinitrophenol is excreted from the body within a few days after taking, so that there could not possibly be any effect on the healing of a wound incurred fifteen months after the administration of dinitrophenol.

The infection sustained in this instance resembles the type of infection so aptly and completely described by Meloney of New York. He finds that a 50 per cent suspension of zinc peroxide in water is a very effective agent in the treatment of these infections. The infection described is probably due to the so-called micro-aerophilic hemolytic streptococcus. Zinc peroxide slowly liberates oxygen in the depths of the tissue and in Meloney's hands has proved an excellent therapeutic agent. There are three cases reported in the literature of similar infections controlled by the use of maggots according to the method of Baer of Baltimore. Allantoin is replacing maggot therapy, and more recently urea, a decomposition product of allantoin, has been indicated as the basic agent in the effectiveness of this therapy.

## ANESTHESIA OF CHILD

To the Editor:—A girl of 6, of what used to be called "nervous temperament," who has a mitral systolic murmur but no other evidence of heart disease, was given ether for a tonsillectomy. No drugs were given before the ether. She went to sleep without any struggle and as soon as she was under the anesthetic her pupils dilated to the fullest extent and would not respond to light. The cornea remained moist. In all other ways she seemed in good condition. Pulse, respiration, etc., were all good, and only a minimum amount of ether was needed to keep her quiet, and the anesthetic was continued until the operation was finished. She recovered well. I was alarmed, because I understood that such pupils are a danger signal unless the patient is coming out of the anesthetic. Did I need to be alarmed? The pupils remained dilated until she was well awake.

C. E. CASWELL, M.D., Wichita, Kan.

ANSWER.—Anesthesia may be divided into several degrees or stages of narcosis. The three stages recognized are the stage of light anesthesia, the stage of deep anesthesia and the stage of paralysis or death. The depth or degree of narcosis may be known by the pupillary reaction to light.

When patients have been given no hypnotic drug as a preliminary to anesthesia, the pupillary reaction is the most valuable guide that the administrator has to the depth or degree of narcosis. Dilatation from operative stimuli is transient and need not be confounded with that produced by the anesthetic. A dilated pupil that reacts quickly to light indicates a light anesthesia. A dilated pupil that reacts slowly to light means a profound anesthesia. A pupil that is widely dilated and does not react to light shows a dangerously deep anesthesia, and respiratory paralysis is at hand. A contracted pupil indicates

of the school board; for many years attending physician at the Utah State Industrial School; aged 69; died, Dec. 28, 1936, of cerebral hemorrhage.

**George W. Moore**, Ashland, Ky.; University of Louisville Medical Department, 1889; member of the Kentucky State Medical Association; formerly county health officer; director and member of the staff of the King's Daughters' Hospital; aged 78; died, Dec. 24, 1936, of myocarditis and chronic bronchitis.

**Jesse J. Adams**, Glasgow, Ky.; Hospital College of Medicine, Louisville, 1890; member of the Kentucky State Medical Association; formerly secretary of the Hart County Medical Society; at one time member of the Hart County Board of Health; aged 70; died, January 6, of heart disease.

**Nathaniel Palmquist**, Smithland, Iowa; Barnes Medical College, St. Louis, 1909; served during the World War; visiting member on the staff of the Methodist Hospital, Sioux City; aged 58; died, Dec. 26, 1936, in the Veterans Administration Facility, Des Moines, of coronary occlusion.

**James Laurence McCarthy**, Butte, Mont.; John A. Creighton Medical College, Omaha, 1900; member of the Medical Association of Montana; county physician and county health officer; on the staff of St. James Hospital; aged 59; died, Dec. 20, 1936, of coronary occlusion.

**Frank Jay Murphy**, Sioux City, Iowa; Rush Medical College, Chicago, 1887; member of the Iowa State Medical Society; served during the Spanish-American and World wars; aged 71; died, Dec. 23, 1936, of carcinoma of the testicle with metastasis to the retroperitoneal glands.

**Andrew Joseph Noome**, Wheeling, W. Va.; Jefferson Medical College of Philadelphia, 1900; fellow of the American College of Surgeons; on the staff of the Wheeling Hospital; aged 67; died, Dec. 4, 1936, of carcinoma of the colon with metastasis to the liver.

**Eugene B. Pribble**, Salem, Ill.; Medical College of Ohio, Cincinnati, 1906; member of the Illinois State Medical Society; formerly member of the city council; aged 59; died, Dec. 30, 1936, of pneumonia, fracture of the hip as the result of a fall, and hypertension.

**William F. X. Dierkes**, Westfield, Mass.; Kansas City (Mo.) University of Physicians and Surgeons, 1920; veteran of the Spanish-American War; on the staff of the Noble Hospital; aged 64; died, Dec. 5, 1936, in Northampton, of cerebral hemorrhage.

**Jesse Lee Russell**, Adairville, Ky.; University of Louisville Medical Department, 1911; also a graduate in pharmacy; past president of the Logan County Medical Society; served during the World War; aged 51; died, Dec. 23, 1936, of heart disease.

**George Moses Felton**, Schenectady, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1910; member of the Medical Society of the State of New York; aged 52; died suddenly, Dec. 31, 1936, in Fort Lauderdale, Fla.

**Septimio Caruso**, Boston; Tufts College Medical School, Boston, 1918; member of the Massachusetts Medical Society; aged 44; died, Dec. 24, 1936, in St. Elizabeth's Hospital, of ruptured diverticulitis of the sigmoid and general peritonitis.

**William M. Lively**, Dallas, Texas; Arkansas Industrial University Medical Department, Little Rock, 1892; formerly professor of obstetrics at Baylor University College of Medicine; aged 72; died, Dec. 27, 1936, of coronary occlusion.

**James L. Seibert**, Bellefonte, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; county medical director; on the staff of the Center County Hospital; aged 85; died, Dec. 29, 1936, of coronary artery occlusion.

**Joseph Wade Thompson**, Independence, Miss.; University of Tennessee College of Medicine, Memphis, 1915; member of the Mississippi State Medical Association; aged 61; died, Dec. 25, 1936, in Sanatorium of pulmonary tuberculosis.

**Frederic D. H. MacMaster**, Syracuse, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1897; veteran of the Spanish-American War; aged 68; died, Dec. 24, 1936, of arteriosclerotic heart disease and bronchopneumonia.

**Gustave Adolph Thielke**, Wausau, Wis.; Milwaukee Medical College, 1903; served during the World War; aged 61; died, Dec. 20, 1936, in the Wisconsin General Hospital, Madison, of hypertensive heart disease and bronchopneumonia.

**Charles Calvin Addoms**, Hondo, Calif.; Ensworth Medical College, St. Joseph, Mo., 1891; formerly a practitioner in St. Louis; aged 84; died, Dec. 16, 1936, of arteriosclerosis, hypertension and chronic myocarditis.

**Louis Philippe Adelard Dorion**, Haverhill, Mass.; School of Medicine and Surgery of Montreal, Que., Canada, 1888; also a druggist; aged 72; died, Dec. 23, 1936, in Montreal, of carcinoma of the descending colon.

**J. Chauncey Huntsinger**, Muskegon Heights, Mich.; Hahnemann Medical College and Hospital, Chicago, 1889; aged 79; died, Dec. 29, 1936, of acute pericarditis with effusion and chronic valvular heart disease.

**John Mettauer Williams**, Roanoke, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; member of Medical Society of Virginia; aged 85; died, Dec. 24, 1936, of chronic myocarditis.

**Elza Carl Porter**, Chicago; University of Illinois College of Medicine, Chicago, 1927; served during the World War; on the staff of the Lake View Hospital; aged 38; died, Dec. 25, 1936, of lobar pneumonia.

**Guy Boyd Maxwell**, Canton, Ohio; Chicago College of Medicine and Surgery, 1911; served during the World War; aged 50; died, Dec. 22, 1936, in the Mercy Hospital, Brownsville, Texas, of nephritis.

**Elwin Otis Church**, Menno, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; aged 64; died suddenly, Dec. 3, 1936, of heart disease.

**Charles William Igou**, Colorado Springs, Colo.; Northwestern University Medical School, Chicago, 1896; aged 66; died, Dec. 23, 1936, of amebic dysentery and coronary thrombosis.

**Ora Waldo Drake**, Grand Rapids, Ohio; Toledo Medical College, 1906; formerly member of the board of education; aged 58; died, January 1, of arteriosclerosis and complications.

**Robert Edward Fortune**, Damascus, Va.; University College of Medicine, Richmond, 1898; member of the Medical Society of Virginia; aged 66; died, Dec. 26, 1936, of pneumonia.

**Redmond O. Davis**, Princeton, Ky.; Hospital College of Medicine, Louisville, 1900; member of the county board of education; aged 68; died, Dec. 23, 1936, of cirrhosis of the liver.

**William H. Farrar**, Hickory, N. C.; St. Louis Medical College, 1875; member of the Missouri State Medical Association; aged 80; died, Dec. 23, 1936, of intestinal obstruction.

**Zuingless U. Loop**, Los Angeles; Kentucky School of Medicine, Louisville, 1882; formerly a practitioner in Galveston, Ind.; aged 85; died, Dec. 27, 1936, of coronary thrombosis.

**E. Herman Wakelee**, Big Flats, N. Y.; University of Maryland School of Medicine, Baltimore, 1884; also a pharmacist; aged 78; died, Nov. 23, 1936, of coronary thrombosis.

**George P. Paschal**, New York; National University of Athens School of Medicine, Greece, 1911; aged 47; died, Dec. 13, 1936, of angina pectoris and coronary sclerosis.

**Rosalie M. Blitzstein**, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1898; aged 62; died, Dec. 25, 1936, of hemiplegia and arteriosclerosis.

**Thomas F. Costner**, Lumberton, N. C.; Jefferson Medical College of Philadelphia, 1882; aged 78; died, Dec. 27, 1936, of cerebral hemorrhage and hypostatic pneumonia.

**Gilbert Simpson Bovard**, Sierra Madre, Calif.; Stanford University School of Medicine, San Francisco, 1922; aged 46; died, Dec. 12, 1936, of pulmonary tuberculosis.

**John C. Toler**, Los Angeles; Missouri Medical College, St. Louis, 1881; aged 76; died, Dec. 18, 1936, of teratoma of the left testicle with metastases to the lung.

**Frank E. Corwin**, Morro Bay, Calif.; Keokuk (Iowa) Medical College, 1897; aged 63; died, Dec. 11, 1936, in Fresno, of gangrene of the leg and arteriosclerosis.

**Joseph Patrick Sweeney**, Springfield, Mass.; Jefferson Medical College of Philadelphia, 1920; aged 43; died, Dec. 26, 1936, of illuminating gas, self administered.

**James Edward Pounds**, Avondale Estates, Ga.; Atlanta College of Physicians and Surgeons, 1911; aged 49; was killed, Dec. 23, 1936, in an automobile accident.

**Jessie Helen MacDonald**, Montreal, Que., Canada; University of Bishop College Faculty of Medicine, Montreal, 1897; aged 76; died, Nov. 24, 1936.

**Joseph Kernochan Miller**, Bloomingburg, N. Y.; Boston University School of Medicine, 1912; aged 56; died, Dec. 13, 1936, of angina pectoris.

tions. If granulations are found, these should be treated with sounds. Sounds should be passed once every five days and allowed to remain in the urethra for two or three minutes and it might be well to massage the urethra on the sound. Following the passage of sounds a urethral injection of from 0.5 to 1 per cent silver nitrate should be done at the office. At home the patient may use a hand injection of 0.26 Gm. of zinc sulfate, alum and phenol in 120 cc. of water, every morning and evening. The complement fixation test would not add anything much in the way of mapping out the program of treatment.

#### INVOLUNTARY BOWEL ACTION IN DIABETIC PATIENT

*To the Editor:*—A diabetic patient consulted me recently concerning a distressing condition; namely, involuntary bowel movements while asleep. He is a white man, aged 29, fairly well nourished, and is able to do office work. He has been under diabetic treatment for about twelve years, during which time he has been hospitalized both for hyperglycemia and for insulin shock. He is doing well now on 30 units of insulin before meals. Last September he had a severe edema of the lower extremities and was told by his doctor that it was due to an existing hyperglycemia. This condition gradually cleared up, but he immediately developed the present bowel trouble. He has complete control of defecation while awake. The involuntary action occurs almost every morning about 3 o'clock. Other history and examination are essentially negative except for an infected antrum, which developed after the present complaint. The blood Wassermann reaction is negative. Paregoric has been taken in large doses and gives slight relief. Please inform me as to the cause and treatment of this condition. Omit name, please, if published.

M.D., West Virginia.

*ANSWER.*—Usually in diabetic patients, diarrhea can be traced to some such cause as colitis, enteritis or achlorhydria, or to some other complication. However, diarrhea without blood or pus in the movements is especially difficult to contend with at night. Sometimes it occurs in young or middle-aged patients. Usually, but not always, it is associated with emaciation and lack of control of the diabetes, and achlorhydria is usually present. Sometimes a deficiency of the external secretion of the pancreas and an increased fat content of the stool can be demonstrated.

In a man, aged 25, recently studied, x-ray evidence of a deficiency disease was shown in the roentgenograms of the small intestine. The treatment of the condition is often unsatisfactory. The use of vitamins, sometimes of liver extract, and adequate control of the diabetes are of fundamental importance.

#### CANCER OF CERVIX IN PREGNANT WOMAN

*To the Editor:*—A sextigravida, aged 35, with four living children, has an epidermoid carcinoma of the cervix proved by biopsy. She is also pregnant at about the four and one-half to fifth month. I sent her to a well known cancer hospital in New York for confirmation of these observations. Epidermoid carcinoma of the cervix also was found, but whereas I felt that it was an early case, the hospital examiners felt that it was midway between the early and the middle stage of growth. Every competent person, from both the obstetric and the radium therapeutic point of view, agreed that one of the following two procedures is the treatment of choice: (1) simple cesarean section with radium treatment of the cervix, and x-ray treatment of the pelvis; (2) simple hysterectomy with radium treatment of the cervix and x-ray treatment of the pelvis. All but one agreed that to allow this woman to carry her pregnancy to completion would be definitely detrimental to her future welfare. The doctor taking exception to this agreement is a very competent man. I would therefore like to obtain your opinion in this matter. Should the woman be allowed to go to term under the circumstances?

M.D., New York.

*ANSWER.*—The pregnancy would have to continue at least ten weeks to secure a viable premature infant whose chances of survival would be about 50 per cent.

Every week during which active treatment of the carcinomatous lesion is postponed lessens the chances of a cure in the mother, who already has four living children, who will need her for years to come.

The best chance for increasing her life expectancy and possibly effecting a cure would be by complete radium and x-ray therapy. This cannot be carried out effectively as long as the pregnancy exists. The production of an abortion by means of x-rays is a questionable and certainly not an established procedure.

In most cases of cervical carcinoma there exists a superimposed infection. An abdominal hysterectomy or cesarean section would carry with it a relatively high mortality. A Porro operation or an incomplete hysterectomy with bilateral salpingo-oophorectomy should be the procedure of choice. Enough cervix could be left to permit subsequent treatment with radium—or such treatment could precede the operation by not more than twenty-four hours. As soon as the operative field is free from

actual or potential infection, high voltage x-ray therapy should be instituted and carried to the limit of tolerance, preferably by the use of six portals with probably a total of about 120 roentgens to each portal. The amount of filtered radium should probably be somewhere between 3,500 and 4,000 hours.

#### FOREIGN BODY AND INFECTION OF TOOTH SOCKET

*To the Editor:*—About six or seven weeks ago annoying pains in the right elbow and knee that existed for some time prompted me to have my teeth roentgenographed, when the dentist found an abscessed second lower left molar, which he proceeded to extract. One root defied his efforts, and he referred me to an oral surgeon in the big city, who completed its extraction. The cavity showed evidence of good healing until two weeks later, when some "proud flesh" appeared in the socket, which was accompanied by some pus and bled easily. The face was slightly swollen. A visit to the oral surgeon resulted in a curetting and packing, with the prognosis of good healing. About two or three weeks later the condition recurred and to this date there is some red, hypertrophied tissue with some pus and bleeding. 1. What could be the cause of this delayed healing of a socket after an extraction? My general health is good and the joint pains that occasioned the extraction have never recurred. 2. Is there a possibility of a malignant condition? 3. Do you recommend another curetting? What other treatment would you recommend? Please omit name.

M.D., Michigan.

*ANSWER.*—1. The usual cause for the symptoms described after the extraction of a tooth is the presence of some foreign body plus infection. The commonest foreign bodies are broken fragments of tooth root not removed in the extraction, and large or small fragments of necrosed bone broken from the supporting bone in the extraction. Rarely are other forms of foreign matter found. As long as the drainage is free, the relief of the systemic symptoms is to be expected.

2. There is virtually no possibility of a malignant condition.

3. The question of another curettement can be decided only by the appearance of the case. The first thing that should be done is to roentgenograph the area to determine the possible presence of foreign bodies. There may be portions of necrotic bone in a case in which the roentgenogram is otherwise negative. If so, the wound will not heal until the sequestrum is absorbed or exfoliated. Roentgen and violet ray treatment are sometimes helpful in these cases.

#### H. G. WELLS AND DIABETES

*To the Editor:*—Is H. G. Wells (British author) a victim of diabetes? Was he an organizer and is he now an officer in a lay organization of diabetic patients? Does he and do they use insulin?

F. GREGORY CONNELL, M.D., Oshkosh, Wis.

*ANSWER.*—Mr. H. G. Wells would undoubtedly resent the implication that he is a "victim" of diabetes. More likely he glories in it and oft repeats to himself those lines of Hemley, written some time ago:

It matters not how straight the gate,  
How charged with punishments the scroll;  
I am the master of my fate,  
I am the captain of my soul.

As a matter of fact, he is president of the "Diabetic Association," an English society organized for the benefit of and service to persons with diabetes. The association issues a quarterly journal of high character in which any diabetic person would find reliable, useful and entertaining information. Full membership in the association is 1 pound 1 shilling and 6 pence a year. All classes of members receive a copy of the *Diabetic Journal*. The address of the secretary, Miss Crerar, is 124 Baker Street, W. 1, London, England.

Insulin is the only medicine recommended by the Diabetic Association for the treatment of diabetes.

#### PROPHYLAXIS OF VENEREAL DISEASE IN FEMALE

*To the Editor:*—In a recent answer to a query you gave the prophylaxis treatment against syphilis, but for the male only. What do you advise for the female? Also what prophylaxis do you advise the female to take against gonorrhea? Please omit name.

M.D., New York.

*ANSWER.*—Chemical prophylaxis, either for gonorrhea or for syphilis, is unsuitable for the female. The best method of protection from either one of these diseases for the female is mechanical prophylaxis; i. e., that the woman insist that her sexual partner wear a condom. While this mechanical protection does not eliminate infection with syphilis from lesions elsewhere than on the penis, and while it obviously does not protect against extragenital infection by kissing, it is nevertheless the only satisfactory prophylactic treatment for the

## CHEMOTHERAPY IN STREPTOCOCCIC INFECTIONS

To the Editor:—One sentence in the leading editorial in THE JOURNAL, January 2, might suggest that my colleagues and I were the first to investigate the protective action of *p*-aminobenzenesulfonamide in streptococcic infections of mice. I should much appreciate it if you would allow me to point out that J. and Mme. Tréfouël, F. Nitti and D. Bovet (*Compt. rend. Soc. de biol.* 120:756 [No. 36] 1935) were the first to show the activity of this substance in streptococcic infections. We were able to confirm their work, and we further showed that the sulfonamide treatment of mice infected with hemolytic streptococci and meningococci (see also Proom, *Lancet* 1:16 [Jan. 2] 1937) was more effective than that with the original prontosil.

G. A. H. BUTTLE, Langley Court,  
Beckenham, Kent, England.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## SKIN DISCOLORATION

To the Editor:—Will you kindly let me know the etiology, treatment and medical term of the condition of skin discoloration, especially during the summer months? This condition is not due to argyria or to "bismuthia," for the patient has not partaken of any of these drugs at any time. Please omit name.

M.D., New York.

ANSWER.—Any pigmentary disorder in which melanin is the pigment concerned is apt to take a deeper shade in the summer, as the production of melanin is stimulated by the more intense light. The query does not state definitely which of the hyperpigmentations is meant; but it is assumed that common sun tan, freckles or pigmented nevi are not intended.

Chloasma is the most common of the really pathologic hyperpigmentations, characterized by patches, usually ill defined, of light yellow to brown or almost black, occurring most frequently in females and located usually on the forehead or cheeks. The lesions may, however, be anywhere on the skin, symmetrical or asymmetrical, even unilateral at times. The skin is of normal texture in most cases.

Many cases of chloasma occur in women who are pregnant or who suffer from pelvic disorders, or even in young girls about puberty, some of whom have chlorosis. Termination of the pregnancy or cure of the underlying disease often clears the complexion. Several recent writers have maintained that a number of these cases are due to avitaminosis, yielding to administration of vitamin C. Schroeder and Einhauser (Ueber einen Zusammenhang zwischen gestörter Vitamin-C-Resorption und pathologische Pigmentierung bei Gastroenteritis und Achylia gastrica, *München. med. Wchnschr.* 93:923 [June 5] 1936) assert, however, that infections of the upper bowel may destroy the vitamin ingested or that achylia gastrica may inhibit its absorption. Because of this they recommend its parenteral administration.

It has long been recognized that hypofunction of the anterior lobe of the pituitary gland may cause abnormal pigmentation, just as disease of the adrenal gland causes the pigmentation of Addison's disease. Exophthalmic goiter, the administration of arsenic over long periods, Hodgkin's disease, leukemia, scleroderma, pellagra and many other diseases are associated with abnormal pigmentation of the skin, subject to increase in the summer.

Tinea versicolor increases in the summer because of increase of sweating. The action of sunlight on skin that has recently been wet with certain perfumes or toilet waters may result in sharply defined patches of pigment.

For the removal of pigment not amenable to treatment of its cause or in the numerous cases in which no cause can be found, local bleaching may be tried, it being kept in mind that too

energetic methods may result in the increase of the color instead of its removal. The commonest method is the application every evening of:

	Gm. or Cc.
Mercury bichloride .....	0.6
Alcohol .....	40.0
Distilled water .....	to make 120.0

M. Sig.: For external use. (Poison.)

This is allowed to dry on and is washed off in the morning. After a number of applications, a slight inflammation may indicate that the process has been carried far enough and the application of the lotion should cease until exfoliation has been completed. Then, if necessary, the process may be repeated.

Other methods of bleaching the skin were mentioned in Queries and Minor Notes in THE JOURNAL, Aug. 22, 1936, page 608.

## ESSENTIAL HYPERTENSION

To the Editor:—A French-Canadian boy, aged 17 years, has had more or less continuous headaches for the last four years confined chiefly to the back and right side of the head. The headache is much worse on exertion and precludes all forms of exercise or games. Physical examination showed a systolic blood pressure of 190, diastolic 120, urinalysis negative. No other pathologic condition is found on examination. The condition is presumed to be one of essential hypertension. Please outline treatment and prognosis. Please omit name.

M.D., Ontario.

ANSWER.—The data presented are inadequate for the formulation of proper treatment or prognosis. It is almost inconceivable that, other than the arterial hypertension, "no other pathologic condition is found on examination." If hypertensive arterial disease is responsible for the boy's headaches and his hypertension and it has persisted for at least four years, as intimated by the duration of the occipital pain, certainly changes in the heart, retinas and kidney function should be detectable. The fact that the urinalysis is "negative" does not preclude impairment of the renal function. In chronic glomerular nephritis, such as may be a late sequel of acute nephritis following scarlet fever, the urine may be free of more than traces of protein and show only a few erythroplasts and casts and yet the ability of the kidneys to concentrate the urine may be grossly impaired.

A truly comprehensive, useful diagnosis should so far as possible include consideration of the probable etiology, the anatomic or organic condition and the degree of functional impairment. Merely giving a disorder a name does not suffice. In view of the patient's youth, certain possible etiologic factors stand out with prominence. The following factors must be considered and either ruled out or proved present: pituitary basophilism, brain tumor (both suggested by the severe headaches), coarctation of the aorta (rare, but a factor one must not forget), nephritis, chromaffin tumor, usually of the adrenal (very rare, but still worthy of thought), and metal intoxication such as from arsenic (exposure perhaps due to previous and unsuspected medication, as with solution of potassium arsenite). Polycythemia vera may also be mentioned as a possible factor. Data regarding the boy's family history might be most valuable in revealing constitutional vulnerability.

In hypertensive arterial disease, commonly called "essential hypertension," it is the rule that the younger the patient the more rapid is the progression of the disease and therefore the darker the prognosis. In brain tumor the prognosis depends not on the hypertension but on the primary disease. A persistent diastolic tension of 120 mm. is of ominous import, particularly if it is fixed and does not fall with vasodilator medication. The amyl nitrite test should determine this point. If the diastolic tension remains relatively fixed, it is more than probable that extensive nephrosclerosis exists. This should be confirmed by renal function studies. Uremia is the more common termination of hypertensive disease in patients as young as this one. On the other hand, hypertension due to coarctation of the aorta offers a relatively good prognosis.

Therapy is dependent on accurate diagnosis and recognition, so far as possible, of the probable etiologic factors. Curative therapy is logically divided into three principles: (1) therapy directed against etiology, (2) therapy to aid in giving rest to the injured structures and (3) therapy attempting to insure adequate tissue nutrition and oxygenation. The first principle is applied in removal of foci of infection, correction of dietary and other indiscretions, attention to noninfective intoxications and recognition of other causative factors. As in hypertensive arterial disease the arterioles, myocardium and renal parenchyma are the structures primarily injured, rest for these is best assured with vasodilator medication, which may (if arteriolar sclerosis is not extensive and if the causative pressor factors are not too active and persistent) reduce the arteriolar spasm, relieve the myocardium of some of the excessive burden and improve the renal circulation. Small, frequently repeated

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, February 20, page 666.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants will be held in various cities throughout the country on April 17. Oral examinations for Group A and B applicants will be held in Philadelphia, June 7-8.* Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination will be held simultaneously in different centers of the United States and Canada in March. Practical examination will be given in St. Louis in April and at Philadelphia in June.* Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants will be held in various cities throughout the United States and Canada, March 6. Practical, oral and clinical examinations for Group A and B applicants will be held at Atlantic City, N. J., must be received at least sixty days prior to the* Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (Pa.).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7. *All applications and case reports, in duplicate, must be filed not later than April 7.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Philadelphia, June 12. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY AND PSYCHOLOGY: Philadelphia, June. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., D. C.

AMERICAN BOARD OF RADIOLOGY: June 4-6. Sec., Dr. Byrl R. Kirklind, Mayo Clinic.

AMERICAN BOARD OF UROLOGY: *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

### New York June Examination

Mr. Herbert J. Hamilton, chief, Professional Examinations Bureau, reports the written examination held by the New York State Board of Medical Examiners at Albany, Buffalo, New York and Syracuse, June 22-25, 1936. The examination covered 9 subjects and included 10 questions. An average of 75 per cent was required to pass. Six hundred and sixty-six candidates were examined, 539 of whom passed and 127 failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
University of Arkansas School of Medicine... (1932), (1934)	2

present immediate management. However, if in his judgment a delay of a few months is not associated with any great danger of marked progression, a change of climate, in the light of these comments, might be in order. Improvement in the skin condition may result in considerable improvement of the general and nervous state, with its associated possible beneficial influence on the eye condition, and favorably influence subsequent operative procedures.

#### PYELITIS IN PREGNANCY

*To the Editor:*—A primigravida one week over seven months, aged 27, weight 115 pounds (52 Kg.), started vomiting early in January, about as usual. Early in April she complained of her urine scalding her and then of frequent urination. In about one week she went to bed with a pronounced chill, a temperature of 103 F., and severe pain in the back midway between the kidney and the bladder, sensitive to touch and not relieved by any medicine or posture. Methenamine made little difference in the slide picture, which had plenty of pus cells, some blood cells, little clumping and no casts. After one week in bed the patient was up and about, feeling well, although medicine was continued, when in a week's time the same chill, temperature and pain recurred. She got so she could not even take water and keep it down. I took away all medicine and sent her to the hospital in care of one of our best surgeons, and now after one week of dextrose intravenously she is back home in bed and taking three meals; but still the first thing in the morning she raises or spits up. Now delivery is as yet seven weeks away. This in my opinion will light up again as soon as she gets about. She certainly cannot lose any more and go that long. If a cesarean is the elected operation, should she be sterilized? I should think that a catheter would be dangerous in a pyelitis of this type. How much longer am I to chance with nature? What will be the borderline here? Please advise me what to do and when to do it or just to keep her in bed. If she becomes pregnant again will the same condition recur or is this the colon bacillus? Please withhold my name.

M.D., New York.

**ANSWER.**—The patient should have ureteral catheterization for drainage of the kidney pelvis if there is persistent pyuria and fever. That should suffice to permit the pregnancy to progress to a normal termination. If nourishment sufficient to maintain nutrition is retained, the blood pressure remains low and the urine remains relatively free from albumin and casts, expectant care is preferable to intervention.

The patient should be at rest, most of the time in bed.

Pyelitis is not, in itself, an indication for sterilization at the time of cesarean section. The general health of the patient and her wishes relative to having more children are equally important factors in determining whether further childbearing should be prevented. Many patients escape recurrence of the pyelitis in subsequent pregnancies.

#### PERIPHERAL NERVE INJURY DURING CHILDBIRTH

*To the Editor:*—I have under my care a 2 weeks old male infant who has a congenital deformity of the right external ear, it being about one-fourth the size of the left. The child has also a right facial paralysis (central). The pregnancy was normal and the labor was short and not difficult. However, the infant was pale and lethargic for about four days after birth. Now it is alert, takes feedings well and is gaining properly. The facial paralysis persists even though there is apparently no evidence of increased intracranial pressure or other neurologic signs indicating an extensive lesion. The questions confronting me are these: 1. Does the facial paralysis result from a birth injury or is it congenital? 2. If either, what therapeutic procedures may be followed advantageously? Should one consider nerve transplanting later? When should plastic surgery be resorted to for correction of the ear deformity? If delay is advised are there any measures that might prove helpful if done in the meantime. Kindly omit name.

M.D., Tennessee.

**ANSWER.**—1. It is possible that facial paralysis may have resulted from a trauma inflicted on the peripheral nerve during birth, in which case the electrical excitability of the area supplied by the peripheral nerve would be diminished or absent. It has also been suggested that retardation of the growth of the external ear and injury to the peripheral facial nerve might be due to the pressure of amniotic bands in utero. In the central or supranuclear form of paralysis either the upper or the lower branches of the facial nerve are involved, and consequently there is an absence of complete paralysis of this nerve. The response to electrical stimulation in cases of facial paralysis of central origin is normal. A lesion of central origin may be due to hemorrhage or edema or aplasia of the nuclear centers.

2. Peripheral lesions frequently recover spontaneously. Treatment with the faradic current has been advised in the later stages. Nerve transplantation would offer no hope in the treatment of this patient.

The congenital deformity of the ear, also known as microtia, may be of variable degree, from defective development to complete absence of the external ear. It has been observed that

most of these malformations occur on the right side. Not infrequently there is associated with this deformity partial or complete atresia of the external meatus or of the auditory canal. Gustav Alexander believes that, on account of the undeveloped condition of the cartilage, plastic operations in this region should not be undertaken until the sixth or eighth year (*Die Ohrenkrankheiten im Kindesalter*, Pfäundler and Schlossmann, *Handbuch der Kinderheilkunde*, vol. 7). Joseph C. Beck (in Jackson and Choates, *The Nose, Throat and Ear, and Their Diseases*) notes that there is great difficulty in obtaining a good cosmetic result when the external ear is more than two-thirds absent. He believes that surgery has not proved equal to the task. Both he and Alexander believe that for the present the use of a prosthesis, the replacement of an absent part by an artificial one, gives the most satisfactory results.

#### MENSTRUAL SKIN ERUPTIONS

*To the Editor:*—A white woman, aged 28, married and childless, has been complaining intermittently for several years of irritation of the inner aspects of the labia minora. This condition presents itself in the form of sebaceous cysts ranging in size from a green pea to the head of an ordinary straight pin. I have removed under local anesthesia two of the larger cysts in toto and have opened the smaller ones and expressed sebaceous material or thin watery appearing pus. At the menstrual period these lesions become extremely painful from the contact of the sanitary pad. I have advised the use of mildly antiseptic and healing douches and also application of butyn or nupercaine ointment. These measures give only temporary relief and in a few days there appear one or two small white heads at the opening of the ducts of the labia. The vaginal secretion is normal in amount and alkaline in reaction. I have not attempted any form of cauterization because the appearance of the cysts and the frequency of recurrence almost prohibit it. Please advise me as to some method of treatment. Please omit name.

M.D., Florida.

**ANSWER.**—The local measures employed would seem in the main to have been rational, though ointments are usually not as satisfactory in the treatment of such local infections as the frequent application, two or three times a day, of some mild antiseptic, such as 5 per cent mercurochrome. As douches have been recommended, it is assumed that the patient has a leukorrhea, which might well be keeping up the vulvar infection. If, as is likely, the leukorrhea is of cervical origin, active treatment of the latter is indicated, preferably with cauterization if there is a definite endocervicitis or erosion.

Increased activity of the vulvar sebaceous glands is normal during menstruation, so that a flare up of the condition at this time is not surprising, aside from possible irritation by the menstrual napkin or discharge. In fact, it is not rare to see vulvar skin eruptions, especially herpes, occurring only in relation to the periods. For this reason it may be worth while to try organotherapy in this case. Good results have been reported in various menstrual skin eruptions from the use of both estrogenic substances and the anterior pituitary-like principles of pregnancy urine. If the former are used, a good plan would be to give theelin or similar type of preparation in hypodermic doses of about 2,500 international units every second or third day, beginning five or six days before the periods and keeping these up until after the period is over. If this is not effective, the same plan may be followed with antuitrin-S or follutein, in an intramuscular dosage of 100 units.

#### TREATMENT OF ASPHALT BURNS

*To the Editor:*—Kindly inform me as to what is the best method of caring for asphalt burns—immediate as well as office care.

C. J. PATTHOFF, M.D., Springfield, Ill.

**ANSWER.**—Asphalt burns and tar burns are characterized by a rapid fixation on the surface of the traumatizing agent. In burns of this type the crust formed by the fixation of the tissues with asphalt or tar may be allowed to remain if it is obvious that the burn is superficial. When the burn is severe and deep, débridement should be done, preferably under gas anesthesia. A satisfactory dressing of the wound following débridement is accomplished by the direct application to the surface of fine mesh gauze (40 by 44), over which fluffs of gauze should be placed. In this second layer, several perforated tubes should be incorporated to serve as a means of keeping the wound constantly wet with saline solution. In large wounds, skin grafting should be resorted to as soon as practicable. When burns are superficial and there has been no fixation of the tarry substance on the surface, tanning of the burned area with 5 per cent tannic acid solution is a satisfactory method of treatment. Butesin picrate ointment is also an efficacious dressing for these relatively mild burns.

The purpose of the book seems to be to present the results of treatment with so-called protein stabilization. This means that sufficient protein is given for the metabolic needs of the mother, the fetus, and whatever protein is lost in the urine. Improvement in patients with preeclampsia and the fact that they have had no patients with eclampsia who were treated with their protein stabilization methods leads him to ascribe the results to this treatment. However, it is well known that most large clinics, with varied types of treatment, many of them almost starvation, have too few cases of eclampsia for study or demonstration to students.

*Die Wege und Ergebnisse chemischer Krebsforschung.* Von Privatdozent Dr. R. Wilhelm, Assistent am Institut für medizinische Chemie der Universität Wien, und Dr. K. Stern. Paper. Price, 9 marks. Pp. 473. Vienna: Aesculap-Verlag, Gesellschaft m. b. H., 1936.

This is an elaborate and comprehensive book dealing with all phases of the relationship of cancer to chemistry in the broadest meaning of both words. It deals with the chemical aspects of cancer etiology, diagnosis and therapy. The broad scope of the book can be seen from the subjects of its chapters: inorganic chemistry, organic chemistry, physical chemistry, ferments, nutrition and vitamins, tumor metabolism, endocrine glands and hormones, immunology, and biologic and chemical tumor diagnosis. Although one might believe it impossible to cover this enormous field adequately in such a comparatively short presentation, this has been accomplished not only by an enumeration of the facts but always with an effort to give a critical evaluation of these facts. Naturally, the value of the chapters is not equal, depending on the actual state of our knowledge as well as on the special interest and experience of the authors. In spite of this, one must appreciate that there is always the tendency not to overemphasize particular sections because of a personal interest but to give every phase of the subject its merited importance. Since in almost all these fields definite conclusions are lacking today and the experimental results as well as the conclusions of different authors are in many instances completely contradictory, naturally this book could not become and was not intended to become a textbook reaching definite conclusions and doctrines. It affords, however, an extremely valuable basis for any one interested in one of these problems, since it gives a comprehensive and reliable summary of what is known today and what is not known. The critical and objective discussion, together with the extensive bibliography, makes the book extremely valuable as a reference work which will be consulted by every one in the future who might need reliable and complete information as to the objective status of these problems without toilsome search in the scattered literature.

*Lecciones de patología médica. Tomo II.* Por el Dr. C. Jiménez Díaz. Half-leather. Pp. 1,403, with 297 illustrations. Barcelona: Editorial Científico Médica, 1936.

It is hard to review a book of this character because of the rather unusual form in which it has been compiled. As explained in the title page, these are a professor's lectures to his class as taken down by a stenographer, lacking in other words the final touches and polish which any work of such technical nature requires. Much of the criticism that could be aimed at this bulky volume probably arises from this cause. There is a lot of valuable, painstaking and perhaps too minute and often unmethodical pathologic information in these pages, especially on the kidneys (548 pages), but also on the nervous system and a number of its diseases, and various lung, heart, gallbladder and bowel conditions, including appendicitis and colitis. Much of it, however, seems rather incoordinated and unnecessarily prolix. Too much space appears also to be taken by the presentation of patients and the discussion of symptoms. Although the characteristics of the audience may explain this, it often deflects the discussion from its textbook nature into a series of clinical reports without general conclusions as to the disease dealt with. A number of original illustrations bring out salient points. Various authors have contributed sections on diagnosis and even treatment, which is a rather unusual feature in a textbook on pathology. On some points the author does not seem to have kept up with the latest developments; for instance, in his statement (p. 1242) that sprue is a disease of the tropics and especially of Puerto Rico. The lack of an index is almost inexcusable in a book of this size and scope.

*Paget's Disease of the Nipple and Its Relation to Surface Cancers and Precancerous States in General.* By Keith Inglis, M.D., Ch.M., Professor of Pathology in the University of Sydney. Cloth. Price, \$13. Pp. 255, with 237 illustrations. New York & London: Oxford University Press, 1936.

This book is a valuable archive of detailed reports of cases of Paget's disease together with excellent and beautiful gross pathologic and histologic illustrations. On the basis of his carefully examined material and a critical consideration of the literature, the author believes that Paget's disease is a special variety of cancer of the mammary ducts, beginning at the junction of the lactiferous duct with the epidermis and growing downward in the epithelium lining the duct wall of the acini as well as outward in the epidermis of the nipple. The most important difference between this disease and diseases that might produce similar changes in the squamous cell epithelium (as for instance Bowen's disease, Paget's disease in other parts of the body and precancerous lesions in the squamous cell epithelium of the mucous membrane of the upper respiratory tract or of the cervix) is that in these conditions the malignant cells originate in situ whereas in Paget's disease the author considers that the cancerous cells have already invaded the epithelium of the overlying skin.

*Apicius: Cookery and Dining in Imperial Rome.* A Bibliography, Critical Review and Translation of the Ancient Book Known as *Apicius de re Coquinaria*, now for the First Time Rendered into English. By Joseph Dommers Vehling. With a Dictionary of Technical Terms, Many Notes, Facsimiles of Originals, and Views and Sketches of Ancient Culinary Objects Made by the Author. Introduction by Prof. Frederick Starr. Boards. Price, \$7.50. Pp. 301, with 49 illustrations. Chicago: Walter M. Hill, 1936.

This cookery book, dating back to imperial Rome, contains some 500 recipes in cookery with a sprinkling of medical formulas and hints as to hygiene. The author of the volume is unknown, and it is presumably a repetition of Greek knowledge compiled by an unknown Roman cook. Especially interesting are the equivalents of our modern cocktails, laxative wines, the salts, vegetable dinners, and the various items which, because of symbolism, were supposed to have special value in relationship to body function. Special interest attaches to the product *Garum*, which was a fish oil made from the livers of fish, exposed to the sun, fermented and preserved. This product in ancient Rome was renowned for its medicinal properties.

*El tratamiento médico-quirúrgico de las supuraciones pulmonares.* Por Hernán Oyangueren M. Prólogo del Dr. Gonzalo Corbalán T. Paper. Pp. 94, with 45 illustrations. Santiago de Chile: Imprenta "Leblanc," 1936.

In this short monograph Dr. Hernán Oyangueren M. reviews his experience in the treatment of pulmonary infections (lung abscess, bronchiectasis, and so on). His opinions follow, in general, those expressed in almost every modern textbook on the subject and in most of the literature of today. The monograph might well be used as a chapter in such a work. Although written in Spanish, it is easily read by any one who has a slight knowledge of that language, and the summary, which is translated into English, makes it available for American physicians. The author demonstrates that even a comparatively small number of cases can be used as a basis of an excellent piece of work, provided sufficient care is taken in their study.

*The Physiology of the Elephant.* By Francis G. Benedict, Director, Nutrition Laboratory, Carnegie Institution of Washington. Publication No. 474. Paper. Pp. 302, with 13 illustrations. Washington, D. C.: Carnegie Institution of Washington, 1936.

By means of an apparatus developed particularly for the purpose, the author was able to make a study of the respiratory exchange in the elephant. This original investigation is associated with the important facts regarding the physiology of the elephant, including the relationship between the weight of the new-born elephant and that of its mother, necropsies, basal metabolism and similar factors. It is interesting to know that the average length of life of an elephant is probably about that of man. Many elephants sleep standing up. The elephant matures sexually at about 10 years of age and its period of gestation is about twenty months. A new-born elephant weighs about 200 pounds. A full-grown elephant drinks about 50 gallons of water a day, preferably warm. The total basal metabolism of the average elephant is 4,900 calories for twenty-four hours. A large elephant produces about as much heat as thirty men.

a moderate degree of anesthesia. In testing the pupillary reaction, the amount of light that strikes the pupil must be taken into account. Naturally, if the light is dull the reaction will not be so active. When elevating the lid, the finger should be gently but firmly pressed close to the margin, and the lid suddenly raised. If the lid is slowly brought up and the narcosis is very light, the reaction may be lost. When there is any resistance to manipulating the lid, the anesthesia is very light, too light for operative work.

In all probability, as only a minimum amount of ether was needed for the anesthetic, the patient was in a stage of light anesthesia and there was no cause for alarm.

#### SPONTANEOUS PNEUMOTHORAX

*To the Editor:*—A man, aged 35, whose past history is negative for any serious illness except for a toxic goiter which was removed ten years ago, suddenly developed a spontaneous pneumothorax on the right side six years ago, although apparently in good health. There was no injury or strain, the left lung was normal, and he had no fever at any time, no loss of weight or weakness, and no cough or sputum. Tuberculosis was assumed to be present and he was kept at rest for three months. The lung expanded completely and x-ray examination showed no evidence of tuberculosis, except some pleural adhesions at the base. The man gained in weight, remained in good health for six years, and then again, without apparent cause, there was a recurrence of the spontaneous pneumothorax on the same side. I would appreciate any suggestions as to cause and further treatment, especially as to prevention of future accidents.

E. M. BERGER, M.D., Chicago.

**ANSWER.**—The most common cause of rupture of the visceral pleura producing pneumothorax is tuberculosis. From 70 to 90 per cent of cases may be traced to this cause. When pneumothorax develops in tuberculosis it is usually seen in moderately or well advanced cases. It may be found in minimal cases in which the initial lesion is situated close to the surface of the lung, more commonly in the lower part of the lung rather than at the apex. The x-ray evidence of pleural adhesions at the base of the lung in this case is at least suggestive of tuberculosis as the cause of the pneumothorax. There is a group of cases, which have been called spontaneous or idiopathic, in which a healthy young person develops pneumothorax without any apparent cause. In such cases it is always difficult to exclude tuberculosis with absolute certainty. The most common cause of spontaneous idiopathic pneumothorax is the rupture of an emphysematous vesicle. These vesicles depend on scar tissue involving a bronchiole in such a manner as to produce expiratory obstruction. There results gradual overinflation of the affected lobule, with ultimate perforation into the pleural cavity. The great majority of these cases occur in the male sex, more than 60 per cent in the third decade. This might be explained in part by the greater physical activity of the sex and also suggests the treatment as to the prevention of future accidents; that is, to lessen the activity of the patient.

#### BITE OF BLISTER BEETLE

*To the Editor:*—I would appreciate information on a case which I have, the history of which is as follows: The patient left my office late one evening and proceeded to his home in Philadelphia by way of automobile. In the course of the drive he felt an insect on the anterior region of his neck, which he crushed and killed where it had alighted. The insect, he states, felt like a beetle. About six hours later he felt an intense burning in this same area on the neck. A few hours later he noticed a large bleb, which peeled off, leaving an area approximately an inch square, which had the appearance and feeling of a severe burn in which the epidermis is destroyed and part of the dermis. Two days later the wound was of the same size, still painful and burning, red, oozing a serous fluid, depressed and sharply margined, with destruction of the superficial layer of the skin. What is the cause of this lesion, what insect could produce it, and what would be the treatment?

M.D., Pennsylvania.

**ANSWER.**—There are many beetles throughout the United States that are related to the *Cantharis* beetle of Europe, from which cantharides powder is made by drying and crushing the bodies. All these insects are known popularly as blister beetles. Some forms are so destructive to potatoes, beans, beets and other vegetables that they have been called potato bugs. They also destroy clematis, asters and other flowers and appear in great numbers in years following those in which grasshoppers have been abundant, as they breed in the ground and their early metamorphic forms feed on the egg cases of the grasshoppers.

One of these blister beetles is so common in Pennsylvania that it is known as the Pennsylvania blister beetle, *Epicautis pennsylvanica*. All forms, as the name implies, have the property, when crushed, of blistering human skin.

The best treatment is prophylaxis. Brush the beetle off respectfully, instead of rudely crushing it. After the bulla

forms, puncture and drain it with care, so that its contents are not left on the neighboring skin, and apply a dry dressing over the collapsed bulla. When the crushed bodies of the beetles come in contact with raw surfaces they sometimes produce serious necrosis. If the top of the bulla has been removed, a cool wet dressing of 8 per cent solution of aluminum acetate may be applied, and then a dressing of 10 per cent boric acid in cold cream.

#### TREATMENT OF SYPHILIS

*To the Editor:*—About a year ago I received the report of an early case of syphilis. The lesion had been diagnosed as a chancre and the darkfield examination had been reported positive by a reliable laboratory. The patient then changed doctors. His present physician told him that he was healed and did not need further treatment and took two Wassermann tests, which were both reported negative. I called the boy in and explained the situation to him, but he is convinced that he is safe and nothing short of armed force, which I hate to resort to, will bring him in for treatment. I dislike also antagonizing the older practitioner by insisting that this case is not closed. I would like your opinion at least for my own satisfaction. To summarize: A young healthy man, aged 20, reports with a clinical chancre, proved by darkfield, and receives a few injections of neoarsphenamine, whereupon the lesion disappears. A month later the Wassermann reaction is negative and he refuses further treatment. Am I within my rights, as assistant health officer in charge of the county venereal clinic, in insisting that he take further treatment? Is the second consultant wrong in advising him that he does not need "any more shots"? What is the ethical thing to do?

M.D., Michigan.

**ANSWER.**—In a seronegative primary syphilis, which the description indicates, continuous treatment for one year should be given. The negative Wassermann reaction mentioned does not relieve the patient of taking or his physician of giving an adequate amount of treatment. Adequate treatment includes approximately twenty-six injections of arsphenamine or its equivalent in neoarsphenamine and from twenty-eight to thirty-two injections of a bismuth compound or its equivalent in mercury. (See Moore, J. E.: *Ven. Dis. Inform.* 10:53 [Feb. 20] 1929.)

#### EPIDIDYMITIS AND PROSTATITIS

*To the Editor:*—A man patient developed a urethral discharge twelve days after sexual intercourse. Fearing gonorrhea, he visited a local doctor. Urethral smears were positive for gonococci. Anterior urethral instillations of 0.5 per cent strong protein silver were instituted by the physician and given daily over a period of two months. Two weeks after the onset of the urethral discharge, a left epididymitis developed, which cleared up in about ten days. However, with the two-glass urine test, shreds persisted in being present in the first glass with the second glass being entirely clear. Because of this, the patient decided to change physicians and came to me two months and one week after onset of the urethral discharge. On examination he presented nontender testicles, normal in size. There was no urethral discharge. The prostate was normal in size and not tender. The first glass of urine showed the presence of a few shreds, the second glass being clear. Treatment instituted was the discontinuance of anterior instillations of strong protein silver and substitution of intradermal injections (0.1 cc.) of Corbus-Ferry gonococcus filtrate every six to seven days. These injections have been given for the past six weeks and also the local use of bacterial antigen daily for the past two weeks. The first urine glass still shows a few shreds with the second glass being clear. A prostatic smear showed no gonococcus organisms. Would a gonococcus complement fixation test be indicated to determine whether gonococcal infection is still present? What does the persistence of shreds in the urine indicate? Does the use of the Corbus-Ferry gonococcus filtrate influence the result of the complement fixation test? Would dilation of the urethra on several occasions aid in clearing up the urine? If so, would full dilation of the urethra be indicated in this case? Kindly omit name.

M.D., New York.

**ANSWER.**—In view of the fact that the patient developed an acute epididymitis following urethral infection, he has, or had at that time, an infection in the prostate and seminal vesicles. Therefore an examination of the strippings from the prostate and seminal vesicles should be made to determine whether or not the strippings show pus. If it is not possible to obtain the expressed fluid at the external urethral orifice, a three glass test should be made and the contents of the third glass centrifuged and the sediment examined for the presence of pus. If there is evidence of prostatitis and vesiculitis the patient should use heat by rectum in the form of a rectal heater or sitz baths and gentle massage every five days, the treatment to be continued until the infection in the prostate and seminal vesicles has cleared up.

The shreds in the first glass mean infection in the anterior urethra. If pus is present at the external urethral orifice, it should be examined for gonococci. If no pus can be obtained, the shreds should be fixed on the slide and stained for gonococci. If no gonococci are found either in the urethral discharge or in the shreds, it is justifiable to examine the anterior urethra with a diagnostic bougie for the presence of granula-

not, the court pointed out, a collateral and conditional promise to pay the debt of the boy's parents, but a primary and direct obligation incurred by the railroad company through the promise of a duly authorized representative. While the acts and promises of the local agent in bringing the boy to the hospital and asking that he be taken care of might not in itself be sufficient to bind the company, yet his acts were ratified by the payment of the ambulance bill incurred in bringing the boy to the hospital and by the subsequent promise by the claim agent to pay the bill. There was no similarity, in the opinion of the court, between the present case and those cited by counsel for the defendants where a person present at an accident calls for medical assistance for one seriously injured without any promise or agreement by the person so making the call to pay for the services, and where the person so making the call owes no legal duty to the injured person to render assistance. In such a case the person is acting the part of a good Samaritan, and no legal obligation is incurred. In the present case, however, the plaintiff proved an agreement to pay for the services. Even though no legal liability for damages may have been incurred by the railroad company because of the accident, nevertheless a claim for damages was made possible by the accident, and the railroad company had an interest in minimizing the damages had the facts developed a liability. At least the company was not in the position of a disinterested stranger.

In the opinion of the court, the judgment of the lower court for the hospital was justified and that judgment was affirmed.—*Eunice Clinic & Hospital, Inc., v. Baldwin et al. (La.)*, 167 So. 868.

**Privileged Communications: Widow's Right to Waive Privilege.**—Section 11494, Ohio General Code, provides in part:

The following persons shall not testify in certain respects:  
 . . . a physician, concerning a communication made to him by his patient in that relation, or his advice to his patient. But the . . . physician may testify (1) by express consent of the . . . patient; (2) and if the . . . patient voluntarily testifies, the . . . physician may be compelled to testify on the same subject.

The appellee's husband died from an injury allegedly sustained in the course of his employment. The appellee, as his widow, was denied benefits by the industrial commission of Ohio. She further prosecuted her claim in the court of common pleas, and to establish the claim she introduced the testimony of a physician who had attended the deceased both before and after the accident. The industrial commission objected to the admission of this testimony on the ground that it came within the purview of the privileged communications statute and that the privilege could be waived only by the patient, that the right to waive does not survive but dies with the patient. The trial court overruled this contention and subsequently gave judgment for the widow. This judgment was affirmed by the court of appeals, and the industrial commission sought a reversal in the Supreme Court of Ohio.

An injured employee, said the court, cannot hide his physical condition and draw compensation under the workmen's compensation act. He must, so long as he lives, give the medical adviser of the industrial commission opportunity to examine him and learn all that his family physician could possibly know. If his dependents make claim for death because of an occupational disease, the industrial commission can pursue his body after death and examine it, before the dependents will be permitted to participate in the state insurance fund. The workmen's compensation act has taken away the privilege the employee enjoyed under the general privileged communications statute. In the present case, the testimony of the attending physician was introduced for the purpose of proving the nature and extent of the personal injuries sustained by the employee. To entitle the widow to death benefits under the workmen's compensation act it was incumbent on her to prove that her husband died from injuries sustained by him during the course of his employment. To do so, it was necessary that she introduce testimony concerning the nature and extent of the injuries sustained by her husband and to establish causal connection between those injuries and his death. To deprive her of the right to waive the privilege accorded by the privileged

communications statute would be to deny her the means of enforcing the rights given to her by the workmen's compensation act. It is inconceivable, said the court, that the legislature intended, on the one hand, to extend to the widow of an employee, whose injuries resulted in death, certain financial benefits, and, on the other hand, to place her beyond reach of such benefits by the interposition of a technical rule of evidence. The privileged communications statute must be construed, the court continued, so as to afford rather than deny to the widow the legal means available for the enforcement of the rights accruing to her under the workmen's compensation act. Furthermore, the weight of authority supports the view that the right to waive the privilege survives the patient. With this view, the court expressed itself as in accord, thereby departing from the holding in a case previously decided, *Swetford v. Miles*, 101 Ohio St. 501, 130 N. E. 22.

The court held, therefore, that the trial court did not err in permitting the attending physician to testify. The judgment of the trial court for the widow was affirmed.—*Industrial Commission of Ohio v. Warnke (Ohio)*, 2 N. E. (2d) 248.

**Evidence: Admissibility of Roentgenograms for Purposes of Comparison.**—The plaintiff's pelvis was fractured when she was struck by an automobile driven by the defendant. She sued the defendant to recover damages and obtained judgment in the trial court. The defendant thereupon appealed to the district court of appeal, third district, California.

The defendant contended that the trial court erred in admitting in evidence, without proper foundation, a roentgenogram of a normal pelvis apparently for the purpose of comparison with a roentgenogram taken of the plaintiff's pelvis. The contention of the defendant was without merit, in the opinion of the district court of appeal. The use of skeletons, charts and diagrams is common in trials to show the normal structure of the human body and the court of appeal could not perceive why the use of roentgenograms of a normal bone arrangement may not likewise be used for illustration and comparison. The roentgenogram offered in evidence was that of the pelvis of a normal woman about the age, size and figure of the plaintiff and, in the opinion of the court, was properly admitted for the purpose of enabling the witness to explain to the jury a roentgenogram already in evidence. Finding no error, the judgment of the trial court was affirmed.—*DeMartini v. McDonnell (Calif.)*, 58 P. (2d) 170.

occasionally exposed female. Sonnenberg of Lodz has been experimenting with the bismuth prophylaxis of syphilis in prostitutes. By means of intramuscular injections of an insoluble bismuth salt, given every two weeks over an indefinite period, even a professional prostitute can be protected against syphilitic infection with a fair degree of certainty.

#### ALLERGIC RHINITIS

*To the Editor:*—A man, aged 36, for the last fifteen years has had sneezing, a running nose and reddened eyes every time he goes to the mountains or the seashore. While there he feels well but on arising in the morning the symptoms appear. He may feel slightly better in the evening but next morning the symptoms appear. He has had submucous resection. He has not had treatments for the nose. Because of the history I am doing the allergic diagnostic tests. Is this the correct procedure? At the present time I have found a two plus positive test for horsehair. Is this enough to cause the symptoms? While in the city, the patient feels well. The reason prompting this letter is whether the present procedure of diagnosis is in keeping with the history. The brother of the patient has hay fever. Please do not publish name.

M.D., New York.

*ANSWER:*—The case is apparently a typical one of allergic rhinitis. The history given does not suggest any clues as to the allergic causes. Skin tests constitute the correct procedure in such a case. If insufficient information is obtained from such tests, intracutaneous tests should be tried. A reaction to horsehair may be significant, especially if there are any horses in the vicinity or if there are any objects in the home in which the hair might be found (mattress, furniture).

#### HEXYLRESORCINOL IN ASCARIASIS

*To the Editor:*—About one year ago there appeared in *THE JOURNAL* an article on the subject of the treatment of roundworm infestation with hexylresorcinol. I should like to know whether this treatment is still considered good and, if so, where these capsules may be obtained. Will you please send all the information available on the treatment of roundworm infestation.

M.D., Pennsylvania.

*ANSWER:*—Hexylresorcinol is considered by some authorities the treatment of choice in ascariasis, as this drug is much less toxic than either santonin or oil of chenopodium. The dosage is 1 Gm. for adults, and from 0.2 to 0.8 Gm. for children 10 years of age. The drug is administered in hard gelatin capsules of 0.2 Gm. each on an empty stomach in the morning followed by a saline cathartic and abstention from food for five hours. Sanitary disposal of feces to prevent ground pollution with *Ascaris* eggs is the requirement of prophylaxis.

#### CESSATION OF FERTILITY IN MENOPAUSE

*To the Editor:*—Is there any test available to the general practitioner whereby he can determine when, in the period of the menopause, a woman is no longer capable of conception? A patient recently stated that his wife, now 42 years of age, had menstruated regularly until about two years ago; then there were one or two scanty menses and since then no menses have occurred. He wished to know whether precautions to avoid pregnancy were still necessary. Hence my inquiry.

M.D., Pennsylvania.

*ANSWER:*—There is no test available for determination of cessation of fertility at the menopause. Testing for the estrogenic hormone is of no clinical value in this type of case.

There is a current impression that women approaching or in the menopause are peculiarly susceptible to conception. Such is not the case. This view has evidently been accepted because women who become pregnant late in their childbearing period are much talked about by their friends and neighbors.

#### DIAGNOSIS OF DIPHThERIA

*To the Editor:*—Is it possible to make a definite diagnosis of diphtheria from a smear alone? Can the laboratory man be certain without a culture? Will diphtheroid and diphtheria organisms have the identical staining appearance and characteristics on the uncultured smear stain?

E. H. COACHMAN, M.D., Muskogee, Okla.

*ANSWER:*—It is not possible to make a definite diagnosis of diphtheria from a smear alone or even from a culture. It is always necessary to consider the clinical symptoms. Diphtheria organisms may be found in smears or cultures taken from the throat or nose of a diphtheria carrier. In cases of active diphtheria, smears taken early might be negative. Diphtheroid and diphtheria organisms cannot be differentiated in an uncultured smear stain in many instances. The diagnosis of diphtheria should be based on the clinical observations and confirmed by nose and throat culture. This does not mean, however, that the antitoxin should be withheld in suspected cases until clinical symptoms are fully developed.

#### HAZARDS OF MOUTH GAG WITH ELECTRIC LIGHT

*To the Editor:*—Please advise me if the Cameron mouth gag with electric light is safe to use with ether anesthesia in the removal of tonsils. This instrument is four or five years old.

JOHN P. SEARLS, M.D., Malakoff, Texas.

*ANSWER:*—So far as we are aware, no accidents have happened with the Cameron mouth gag equipped with an electric light and used with ether anesthesia for tonsillectomy. So long as all connections are secure so that no short circuit or sparking can occur, there seems no reason why this sort of mouth gag should be a menace. We know that it has been used by some operators for some time and believe that with the precautions mentioned its use should be safe.

#### FLUID IN CHEST

*To the Editor:*—A man, aged 74, about four weeks ago developed a cough with free fluid in the left side of the chest. His temperature has been normal for the past three weeks; x-ray examination reveals a moderate amount of free fluid present. This fluid seems to be absorbing very slowly. Would diathermy to the chest help? I hesitate to aspirate because of the patient's age, and complications set in from aspiration. His temperature has been normal and he feels well except for occasional coughing. He feels better with the chest strapped. Any suggestion besides the use of diathermy will be appreciated.

JOSEPH A. SILEO, M.D., Brooklyn.

*ANSWER:*—If the temperature is normal, the fluid is best left alone. At that age there may be some circulatory element, and a mild diuretic, such as some form of theobromine, might be tried. Diathermy is not indicated.

#### DURATION OF POTENCY IN MALES

*To the Editor:*—At about what age does the average male in good health cease to have live active spermatozoa? When does he become impotent? Please omit name.

M.D., Mississippi.

*ANSWER:*—The fact that there are authentic cases of men over 90 who have impregnated women shows that potency and spermatic function can persist to very old age. Even in men who have ceased to cohabit on account of their age, live spermatozoa have been found at necropsy in the seminal vesicles. The average normal man ought to be able to indulge in coitus between 65 and 70 years of age. In the normal individual, live active spermatozoa should persist at least as long as ejaculation is possible.

#### "ICTERUS DURING THE TREATMENT OF SYPHILIS"

*To the Editor:*—In reading *Queries and Minor Notes* in *THE JOURNAL*, January 2, page 67, I noticed that the answer to the query entitled "Icterus During the Treatment for Syphilis" recommended the cessation of arsphenamine therapy during icterus. I should like to call attention to the article by Jankelson and me, entitled "Treatment of Arsenical Hepatitis with Sodium Dehydrocholate" (*Arch. Dermat. & Syph.* 32:422 [Sept.] 1935). In a case of early active syphilis, in which vigorous antisyphilitic treatment is indicated, I have shown that it is possible to continue arsenical therapy, even in the presence of jaundice. If there is bile in the stools, and this is the only important factor to consider, each dose of the arsphenamine may be mixed with 10 cc. of 5 per cent solution of decholin sodium and slowly administered intravenously. Just before each injection blood is withdrawn in a dry, sterile syringe for a quantitative van den Bergh determination. If the figures of this determination show a progressive decrease or if they do not increase, the treatments are continued. Eventually the icterus clears up and treatment may be then continued, either with or without the decholin sodium, cautiously.

If, however, there is no bile in the stools, this treatment is not indicated. The protective effect of the decholin sodium (sodium dehydrocholate) on the liver is entirely adequate for the dose of arsphenamine that is being administered, provided there is some flow of bile out from the liver into the intestinal tract. In such a case there is also a curative effect on the damage already done, because of the washing out effect which the cholerisis produced by this drug establishes. Sodium thio-sulfate is a very poor second under these circumstances.

BERNARD APPEL, M.D., Boston.

#### HEIGHT, WEIGHT, AGE RELATIONSHIP IN CHILDREN

*To the Editor:*—In *Queries and Minor Notes* in *THE JOURNAL*, January 16, page 227, a physician asks for a height, weight, age chart, or a method of calculation. He might be interested in an article by Dr. David Willoughby of Los Angeles, who wrote an article entitled "An Anthropometric Method for Arriving at the Optimal Proportions of the Body in an Adult Individual," published in the *Research Quarterly* of the American Physical Education Association, volume 3, No. 1, 1932.

C. H. WARFIELD, M.D., Wichita, Kan.

**Blood Studies in Tuberculosis Before and After Thoracoplasty.**—Muller analyzed and correlated blood studies, including the corrected sedimentation rate and leukocytic counts, to various factors in forty-seven cases of pulmonary tuberculosis, prior to thoracoplasty and six months after the operation. Patients with a favorable leukocytic index and with a normal or practically normal sedimentation rate before a thoracoplasty are likely to respond well to the operation. Patients with marked activity of the disease process, as revealed by the leukocytic index and the sedimentation rate, likewise respond well if the trend of the blood, as revealed by serial examinations, indicates progressive improvement before the operation. Patients who shortly before the operation show an increase in the sedimentation rate and the leukocytic index and a neutrophilic shift to the left on serial examinations do not derive the expected benefit from the operation and some are made definitely worse. More reliable information is obtained by evaluating all factors combined than by the consideration of a single factor alone.

## Experimental Studies in Carotid-Jugular Anastomosis.

—The phenomena that Blakemore and his associates observed following anastomosis of the carotid artery to the jugular vein

in dogs resembled those reported by previous workers following both experimental and clinical arteriovenous communication between other vessels: there was dilatation of the artery between the fistula and the heart, the heart was both dilated and hypertrophied and the cardiac output was increased greatly. These phenomena differed from those previously reported in the greater degree of the changes in proportion to the size of the fistula and in the fact that hypertension ensued. These differences can be explained by the more direct effects on the carotid sinuses of carotid-jugular fistulas than of fistulas between other arteries and veins. In view of these effects, the production of a carotid-jugular fistula as a therapeutic procedure seems ill advised in any case, is contraindicated in degenerative diseases of the aorta and is dangerous in cases with cardiac damage.

## Prophylactic Foot Treatment in Diabetes Mellitus.

By comparing a group of diabetic patients whose foot ailments were attended to with a group that had no such care Brandaleone and his colleagues find that, in the group in which neither the diabetes nor the feet had been treated, 41.6 per cent required amputation and 38.4 per cent of these patients died. In their clinic group prior to prophylactic foot care, 32.4 per cent required amputation and 8.8 per cent died. Previous control of the diabetes improves the prognosis in a patient with infection of the feet, but, if prophylactic care of the feet is carried out systematically at the same time, the prognosis is improved greatly. Care of the diabetes alone improved the prognosis 77 per cent; when prophylactic foot care was added to this, prognosis improved 90.5 per cent. The major portion of infections occurred between the ages of 50 and 70. There was a definite rise in infections after 40 years of age. The large and small toes were involved almost equally. The care of diabetic patients should include prophylactic foot treatment as a routine part of the treatment. This involves the recognition of vascular inadequacies of the extremities and their dangers to the patient and should always be under the supervision of a physician. The most frequent cause of infection of the feet in these patients is improper shoes. This superimposed on arteriosclerosis, which undoubtedly exists in patients of the age group most frequently involved, is too much for the resistance of a patient with diabetes mellitus.

**Development of Tuberculosis in Adult Life.**—In schools of nursing and medicine where the students come in contact with tuberculous patients, in the absence of an adequate technique for dealing with contagious disease there has in recent years been presented an opportunity to study the development of tuberculosis in young adults that is rarely equaled by animal experimentation. Since 1927 Myers and his associates have seen many students of nursing and medicine become contaminated with tubercle bacilli for the first time, the evidence of this contamination being a positive reaction to tuberculin which appeared after the student was exposed to tuberculous patients. In many of these students there has been no other manifestation of tuberculosis as yet. They are classified as having the first infection type of disease somewhere in their bodies, with the location undetermined. Among this group they have observed subjects in whom, after the tissues had become sensitized, lesions developed in such locations or to such an extent that

## Book Notices

**Food, Health and Income: Report on a Survey of Adequacy of Diet in Relation to Income.** By John Boyd Orr. Boards. Price, \$1. Pp. 72. New York & London: Macmillan & Co., Limited, 1936.

This book reports the results of a large scale investigation of the nutrition of the people in the British Isles, which was carried out by the staff of Rowett Institute in cooperation with the Market Supply Committee. It attacks the problem of nutrition from a more fundamental and comprehensive standpoint than has heretofore been done, for it considers the food supply of the country in relation to the nutrition and health of the people and to their incomes. The total food supply of the country was estimated from agricultural statistics and records of imports, exports and manufacturing output. The nature of dietaries for six different income levels was obtained through analysis of 1,200 family budgets secured in various sections of the country. The adequacy of the diets was determined by comparison of their yield of dietary essentials with Stiebling's standards (U. S. Bureau of Home Economics, Diets at Four Levels of Nutritive Value and Cost). The health and nutritional status was judged by the growth of children in the different income levels, the incidence of diseases in which nutrition plays a part, and the results obtained by supplementary feeding of children of the lower income groups.

The outcome is such as to raise important economic, political and health problems. The total national weekly income was found to average about 30 shillings a head, of which 9 shillings, or about one third, goes for food. In the three lower income groups (under 20 shillings) the food money is less (4, 6 and 8 shillings) but its percentage of the income is higher (from 45 to 60 per cent). The consumption of particular foods shows a striking relation to income. Expenditures for fresh milk, butter, fruit, fresh vegetables, eggs, fish and meat—the foods that are depended on to furnish the protective minerals, vitamins and high quality protein—rise sharply in the three upper income groups, while those for condensed milk and margarine decrease in the same order. The expenditures for cereals, fats and potatoes are similar for all incomes. When the diets obtained in the family budgets are analyzed, the degree of adequacy is also seen to rise with the income. The average diet of the poorest group, which includes four and a half million people, is deficient in every dietary constituent; the diet of the second group comprising nine million people is deficient in all the vitamins and minerals; and though the diets of groups 3 to 5 show progressive improvement, all are lacking in some of the dietary essentials. Only group 6, comprising only 10 per cent of the population, with an average income of 45 shillings per head and a food expenditure of 14 shillings, has a diet that is completely adequate.

The physical status is what would logically be expected from the food consumption studies. Growth data on nearly 68,000 children of different socio-economic levels show striking superiority in height of children in the more favored groups; a difference of 2½ inches at 13 years and of 3½ inches at 17 years.

The incidence of dietary diseases, such as rickets, anemia, dental caries and tuberculosis, is—so far as can be determined from available evidence—also greater at the lower economic levels. That these deficiencies are due to dietary inadequacies rather than to hereditary limitations has been demonstrated by a number of supplementary feeding projects. Such studies of hundreds of children in various parts of the country have shown marked improvement in growth for the supplemented groups as compared with the controls.

Considering these observations in relation to one another, the author concludes that the standard which should be held for the country is that of optimal, not minimal, requirements and he tentatively assumes that this level is the one reached by the higher income groups whose diets were completely adequate. To attain this ideal for the entire country "would involve increases in consumption of a number of the more expensive foodstuffs, viz., milk, eggs, butter, fruit, vegetables, and meat, varying from 12 to 25 per cent."

It is pointed out that the economic, political and health problems involved are not within the sphere of any single department of state and that their solution would involve concerted and cooperative action on the part of all. The conclusions in the report are already being given serious consideration by the departments concerned and "the prominence given to this new social problem at the last assembly of the League of Nations shows that it is occupying the attention of all civilized countries."

**Gesetz zur Verhütung erbkranken Nachwuchses vom 14. Juli 1933 nebst Ausführungsverordnungen.** Bearbeitet und erläutert von Dr. med. Arthur Gütt, Ministerialdirektor im Reichsministerium des Innern, Dr. med. Ernst Rüdin, o. ö. Professor für Psychiatrie an der Universität und Direktor des Kaiser Wilhelm-Instituts für Genealogie und Demographie der Deutschen Forschungsanstalt für Psychiatrie in München, und Dr. jur. Falk Ruttko, Geschäftsführender Direktor des Reichsausschusses für Volksgesundheitsdienst beim Reichsministerium des Innern. Mit Beiträgen: Die Eingriffe zur Unfruchtbarmachung des Mannes und zur Entmannung. Von Geheimrat Prof. Dr. med. Erich Lexer. Die Eingriffe zur Unfruchtbarmachung der Frau. Von Prof. Dr. med. Heinrich Eymers. Second edition. Cloth. Price, 9 marks. Pp. 418, with 26 illustrations. Munich: J. F. Lehmanns Verlag, 1936.

This book in somewhat more abbreviated form was reviewed in THE JOURNAL Sept. 29, 1934. In the second edition it has been enlarged and revised. Eymers is substituted for Döderlein as author of the technical aspects of sterilization in women. Otherwise the authorship appears to be unchanged. The greater part of the revision since the first edition is in the introductory portion, dealing with the genetics of the diseases for which sterilization has been declared mandatory in Germany. There is also a much greater emphasis laid on the studies outside Germany and the development of sterilization laws in other countries. Thus, the laws relative to sterilization both of the United States and of Canada are discussed. No apparent change has been made in the laws as they exist in Germany since the first edition. The book contains a satisfactory glossary, and a bibliography that should be useful to any one interested in eugenics. Although national mandatory sterilization seems to be not yet wholly justified by scientific knowledge, there is no choice but to observe closely the results of the German experiences. Even if nothing else is accomplished, the results should aid in the formulation of eugenic policies elsewhere. It is to be hoped that the next edition will include some preliminary criticism of the policies so far pursued.

**A Study in Pre-Eclampsia and Eclampsia with Special Reference to Protein Stabilization Treatment.** Compiled by Boyd Harden, Instructor in Obstetrics. From the Department of Obstetrics, School of Medicine, University of Pittsburgh, and the Elizabeth Steel Magee Hospital. In Affiliation with the Departments of Medicine, Chemistry, Pathology, Ophthalmology, Otology, Laryngology and Rhinology of the School of Medicine. Paper. Pp. 99, with illustrations. Pittsburgh: University of Pittsburgh, 1936.

The author, in a small book of which the bibliography fills twenty-two pages, has attempted to present certain of the chemical and metabolic changes which occur in normal pregnancy and eclampsia. The style is supposed to be terse but becomes choppy and quite often difficult to read. Little space is devoted to hemoglobin, and here the author uses percentages but does not give the standard to which the percentage refers. He also ascribes significance to changes in hemoglobin of from 6 to 10 per cent. There seems to be no definite system to the arrangement of subject matter. For example, one finds data for normal pregnancy interspersed in the chapter in which the author is presenting his views on the stabilization of eclampsia.

chiatrist for diagnosis and treatment. At least 45.5 per cent of the so-called functional cases were incorrectly diagnosed and unsuccessfully treated as cases of hyperthyroidism. The anxiety syndrome occurs in an individual who is tense and uneasy and is characterized by rather suddenly occurring, transient attacks lasting from a few seconds to an hour, during which the patient subjectively experiences difficulty in breathing, palpitation, precordial discomfort, perspiration or "cold sweats," vertigo, various complaints referable to the gastro-intestinal tract and a feeling of weakness. With these attacks there is invariably existent an underlying and accompanying emotional factor which is best described by the term "anxiety." If the physician elicits the complete complaint, he will usually learn that the patient has difficulty in sleeping, has some anorexia, tires easily, has a "tight" pain in the head, feels slowed up or confused in his thinking, is irritable, is restless, has lost weight, has not been up to par for some time, "feels worried" without knowing what about or why, and almost always feels cold and "cannot get warm enough." The first step in therapy is the elicitation of the complete complaint of the patient. Any situational factors dominant in the production of the illness must be altered if possible, or, if impossible, the patient, through discussions, should be led either to accept the facts as they exist or to modify his attitude toward them. Practically never is one situation or one factor the whole cause of the illness. Any medication given such a patient should be accompanied by a careful and painstaking explanation that the particular medication is only a means of giving symptomatic relief. In the young and middle aged, barbitol in doses of 1 grain (0.065 Gm.) morning and noon, and perhaps 2 grains (0.13 Gm.) at bedtime, will relieve the patient of considerable tension and uneasiness and thus promote clearer thinking, make less likely the occurrence of an anxiety attack, relieve the head sensations and allow for more adequate rest and sleep. In elderly patients isobutylallyl barbituric acid seems to be better tolerated. When gastro-intestinal symptoms exist, 10 drops of tincture of belladonna three times daily, liquid petrolatum and a full diet with some roughage have proved helpful. If the gastro-intestinal symptoms are due more to an atonic condition of the intestine, ergotamine tartrate in doses of 1 mg., twice daily, for a few days, often gives relief. In case of a profound and prolonged anxiety attack with a tendency of the patient to become panicky, acetylcholine bromide in a dose of 1½ grains (0.1 Gm.), given intramuscularly, may aid in ameliorating the attack and thus save the patient from panic.

- Angina Pectoris. A. J. Schwertman, Covington.—p. 35.

**Sulfur Therapy in Arthritis.**—Parmenter administered a solution containing alkaline sulfides and colloidal sulfur to patients with varying types of arthritis, chiefly atrophic. The treatment resulted in complete recovery in 30 per cent of the cases, with relief of pain and reduction of joint swelling; considerable improvement in function in 58 per cent, and no improvement except perhaps in appetite, sleep and general well being in 12 per cent. The results indicate that sulfur in the form used, administered concurrently by bath and orally, has no toxic effect on the system. Rather its action is definitely detoxifying and nonirritant to a degree not true of other drugs in arthritis. It tends to normalize body metabolism and revitalize cell tissues by replenishing existing sulfur deficiencies, as demonstrated by its favorable action on blood pressure, weight and the patients' general symptomatology. Sulfur therapy seems definitely indicated in arthritis and its results, with this method of administration, have been very satisfactory. The healing action of sulfur on the kidneys was quite evident when patients had such complications incidental to the arthritis.

### MEDICOLEGAL ABSTRACTS

**Malpractice: Rubber Drainage Tube Left in Patient; Accrual of Right of Action.**—The defendant, a physician, performed an abdominal operation on Mrs. Huysman, Jan. 3, 1931. A rubber drainage tube was accidentally left in the patient. It was removed by the defendant, Sept. 26, 1932. Mrs. Huysman and her husband filed suit, Jan. 7, 1933, attributing her postoperative suffering to the defendant's negligence in failing sooner to remove the tube. The trial court held that the plaintiff's cause of action arose when the defendant failed to remove the drainage tube after it had served its purpose, namely, Jan. 9, 1931, and that since in California a malpractice suit must be instituted within one year after the cause of action arises, the plaintiffs' suit was barred by the expiration of that time limit. The district court concurred in the judgment of the trial court (*Huysman v. Kirsch* (Calif.), 47 P. (2d) 332; abstr. THE JOURNAL, Feb. 1, 1936, p. 410), and the plaintiffs appealed to the Supreme Court of California.

It is settled in California, said the Supreme Court, that an action by a patient against a physician, for injuries resulting from negligent or unskillful treatment, sounds in tort and is barred unless suit is instituted within one year after the date of the injury. When did the cause of action arise in the present case? In *Sly v. Van Leugen*, 198 N. Y. S. 608, a sponge left in a patient was not removed until two and one-half years thereafter. It was held that the patient's cause of action accrued on the removal of the sponge. In *Gillette v. Tucker*, 67 Ohio St. 106, 65 N. E. 865, another sponge case, the court said:

The facts in the case at bar show a continuous obligation upon the plaintiff in error so long as the relation or employment continued, and each day's failure to remove the sponge was a fresh breach of the contract implied by the law. The removal of the sponge was a part of the operation, and in this respect the surgeon left the operation uncompleted.

The foregoing authorities, said the Supreme Court of California, announce a just and equitable rule and the present case is much stronger than either of the cases cited. In each of those cases the negligent act consisted in not removing the sponge at the time of the operation. The negligence there occurred in the performance of the operation. In the present case the operation, up to the closing of the wound and the leaving of the drainage tube therein, was entirely proper. The negligence occurred thereafter, when the surgeon neglected to remove the tube after it had served its purpose. The negligence continued during the entire time the tube was left in the body of the patient and ended only when it was removed. The plaintiffs' cause of action, therefore, accrued at the time the tube was removed.

There is another principle, said the Supreme Court, on which it might be held that the plaintiffs' cause of action is not barred. An operation like that performed on Mrs. Huysman is not complete until the wound has been closed and all appliances used in the operation have been removed. In *Barnett's Administrator v. Brand*, 165 Ky. 616, 177 S. W. 461, the court said:

In performing an operation, it is the duty of a surgeon to exercise reasonable care and skill. The operation begins when the incision is made and ends when the opening has been closed in the proper way, after all the appliances necessary to a successful operation have been removed from the body. Throughout the operation the law imposes on the surgeon the duty of exercising such care and skill. The removal of the sponges or pads is a part of the operation, and an operation cannot be said to be concluded until such removal takes place.

If the principle thus announced, said the Supreme Court, is applied to the present case, the plaintiffs' cause of action is not barred. Furthermore, it has been held that the statute of limitations should not run against an injured employee's right to compensation during the time the employee was in ignorance of the cause of his disability and could not with reasonable care and diligence ascertain such cause. *Marsh v. Industrial*

*Accident Commission*, 217 Calif. 338, 18 P. (2d) 933. If the principle thus laid down is applied to the present case, said the court, the same result will follow, since the plaintiffs had no knowledge of the presence of the drainage tube in the body of Mrs. Huysman until it was removed Sept. 26, 1932. During all this time she was under the exclusive care of the defendant, and both Mrs. Huysman and her husband relied solely on him for information as to her physical condition and as to her failure to regain her health.

For the reasons stated, the judgment of the superior court for the defendant was reversed.—*Huysman v. Kirsch* (Calif.), 57 P. (2d) 908.

**Privileged Communications: Nurses Not Entitled to Privilege.**—Under the common law, communications between a patient and a physician were not privileged. An Indiana statute, however, provides that the following persons, among others, shall not be competent witnesses:

Physicians, as to matter communicated to them, as such, by patients, in the course of their professional business, or advice given in such cases.

This statute, said the appellate court of Indiana, in banc, is in derogation of the common law and must be strictly construed. The statute refers specifically to "physicians." The privilege does not extend to third persons who are present and overhear a conversation, unless such third person was necessary for the purpose of transmitting the information to the physician. The Supreme Court of Indiana, in *William Laurie Co. v. McCullough*, 174 Ind. 477, 90 N. E. 1014, 92 N. E. 337, Ann. Cas. 1913A, 49, defined the term "physician" as follows:

"The word 'physician' is defined to mean a person who has received the degree of doctor of medicine from an incorporated institution; one lawfully engaged in the practice of medicine." 30 Cyc. 1544.

A nurse, said the appellate court, certainly does not come within this definition and any observation of her own could not be a privileged communication within the meaning of the Indiana statute. To the argument that public policy demands that nurses be included within the privileged class, the court replied that this was a matter solely for the legislature, and that the statute could be extended to cover nurses only by it and not by judicial construction.—*General Accident, Fire & Life Assur. Co., Limited, of Scotland v. Tibbs* (Ind.), 2 N. E. (2d) 229.

**Compensation of Physicians: Liability of Railroad Company for Medical Services Rendered at Request of Claim Agent.**—A boy was severely injured while attempting to board a train of the New Orleans, Texas and Mexico Railway Company. The local agent secured an ambulance and had the boy sent to the Eunice Clinic and Hospital, Inc. The serious nature of the injury necessitated an emergency operation and the boy's leg was amputated on the same day of the accident. The following day, a claim agent of the railroad company whose duty it was to investigate accidents came to the hospital to see the boy. In response to a question propounded by the president of the hospital corporation as to who would be responsible for the expenses, the claim agent replied, according to the testimony of the president: "We will take care of the expenses of this case." The claim agent subsequently denied making this statement. Following a refusal of the company to pay expenses, the plaintiff hospital instituted suit against the defendant trustees of the railway company. Judgment was rendered for the plaintiff, and the defendants appealed to the court of appeal of Louisiana, first circuit.

There can be no serious question, said the court of appeal, of the authority of the claim agent to bind the railway company. He was vested with full authority to handle accident cases of this kind. While he denied having stated that the company would take care of the expenses, other facts and circumstances in the record indicated to the satisfaction of the court that he did make such a statement. The defendants objected to the introduction of evidence to show a promise on the part of the railway company to pay the bill on the ground that it was an effort to prove by parol testimony a promise to pay the debt of a third person—the debt being that of the boy's parents—contrary to article 2278 of the Civil Code. This was

**Appendectomy for So-Called Chronic Appendicitis.**—During the last few years Feldman has encountered a large number of adult patients on whom an appendectomy had been performed for so-called chronic appendicitis in order to obtain relief of their symptoms. A thorough painstaking roentgen examination of the gastro-intestinal tract, gallbladder, colon and genito-urinary tract, including cystoscopic and pyelographic studies when indicated, is necessary in every case of suspected chronic appendicitis. In a study of 115 cases of so-called chronic appendicitis, following removal of the appendix, the roentgen examination revealed pathologic conditions other than in the appendix, which accounted for the gastro-intestinal disturbance. Peptic ulcers accounted for 36.5 per cent of the disorders, pathologic states of the gallbladder for 26 per cent, and the genito-urinary tract was involved in 6 per cent. The differential diagnosis of chronic appendicitis is almost impossible without the aid of roentgen studies, by which means a large number of conditions producing gastro-intestinal symptoms that closely mimic appendical disease may be ruled out. In no instance should operative measures be undertaken for chronic appendicitis until all other conditions have been eliminated. The roentgen method of investigation is of the greatest importance as an aid in the ultimate diagnosis.

\*Interrelationship of Vitamin A and Glycuronic Acid in Mucin Metabolism. I. A. Manville, Portland, Ore.—p. 44.

**Vitamin A and Glycuronic Acid in Mucin Metabolism.**—To throw light on the mechanism of mucus production, Manville instituted means to deplete the glycuronic acid of experimental animals. He has gained the impression that the fundamental cause of ulcerative and erosive changes in the gastro-intestinal mucosa is due to the presence in the body, from any source whatever, of toxins so constituted that for their detoxication they must be conjugated with glycuronic acid. The demands for detoxication evidently take precedence over the demands of mucin production, with the result that, when there is a sufficient accumulation of toxins, erosion and ulcers in the gastro-intestinal tract will develop. Since the conjugation of glycuronic acid and toxins occurs in the liver, any impairment in hepatic function will predispose to an earlier appearance of mucosal damage. It appears that vitamin A is involved in this mechanism. The evidence of Clausen and others that the reserves of vitamin A or its provitamin are nearly, if not entirely, exhausted in septic diseases is not to be explained entirely on the basis of impaired absorption. The fact that it does not seem probable that all the benefit derived by vitamin A deficient animals, when fed whole apple, is due to vitamin A only is further evidence in this connection.

\*Physiologic Changes in Ureter Associated with Pregnancy: Relationship Between Atony and Dilatation of Tract. H. F. Traut, C. M. McLane and Alberta Kuder, New York.—p. 51.

**Cardiac Asthma and Acute Pulmonary Edema.**—Teel and his associates have observed a dramatic and dangerous syndrome, which they call "cardiac asthma," in the course of severe nonconvulsive toxemia. In these cases the toxemic patient, while at bed rest, often without previous dyspnea or signs of embarrassment of the pulmonary circulation, is seized with a severe paroxysm of dyspnea associated with extreme orthopnea, cyanosis and acute pulmonary edema. The behavior of these nonconvulsive toxemic patients suggests an explanation for the development of acute pulmonary edema in eclampsia as well. When cardiac asthma and acute pulmonary edema

have occurred during the course of nonconvulsive toxemia it may be that hypertension, coronary disease or nephritis was present before the onset of pregnancy. This has been particularly true of a number of emergency patients in whom past histories and knowledge of the blood pressure and uric acid observations in the early months of pregnancy were lacking. The case histories of six toxemic patients who developed this syndrome are presented. None of them had valvular heart disease. There were known past histories and prolonged subsequent observation in some, and a necropsy was obtained in one instance. Study of these cases seems to indicate that, in at least four, previous hypertension, coronary disease and nephritis were not involved and that the symptom complex of cardiac asthma and acute pulmonary edema may complicate simple acute preeclampsia. The immediate prognosis for patients who develop this syndrome is grave. If they survive delivery and the early puerperium, the ultimate outlook as regards chronic cardiovascular and renal disease seems to be good. Left ventricular failure may be an important factor in the precipitation of these attacks of "cardiac asthma" in patients with severe preeclampsia. It may also play a dominant part in the production of acute pulmonary edema in eclampsia. The fact that a number of the preeclamptic patients recovered indicates that such left ventricular failure is not necessarily an agonal phenomenon. It might be advisable as a prophylactic measure to digitalize all eclamptic patients and those patients more than 30 years of age who have severe toxemia.

**Changes in Ureter in Pregnancy.**—Traut and his co-workers present new evidence indicating that the physiologic dilatation of the ureter in pregnancy is not due to the weight of the pregnant uterus primarily, although this is undoubtedly a contributing factor. The characteristics of the ureteral atony are thought to be similar in many respects to that affecting the uterine musculature. It is suggested that the phenomena in the two organs may have a similar etiology which is unknown. The ureteral dilatation is roughly proportional to the degree of atony, and both appear and disappear at similar times with regard to the course of pregnancy. Dilatation and atony appear in the third month and are progressive to the seventh month of pregnancy. During the last two months there is a marked increase in motility, accompanied by a moderate decrease in the dimensions of the tract. Following delivery, atony is again marked until the third week, subsequent to which motility returns rapidly to normal levels which are usually attained during the sixth or the seventh week post partum. Dilatation of the tract decreases progressively after delivery and reaches practically the normal values at the seventh week of the puerperium.

**Chorea and Rheumatic Activity.**—Coburn and Moore made a study of the incidence of chorea in relation to rheumatic activity. The material consisted of 114 patients with chorea who have been seen once a month in the rheumatic clinic for from two to ten years and 137 consecutive admissions to the Babies Hospital for chorea. In the rheumatic clinic group, thirty-four of 114 patients with chorea failed to develop any evidence of rheumatic activity other than repeated chorea. In the Babies Hospital group, sixty-nine attacks of chorea occurred in patients without either history or stigmas of rheumatic disease. The other sixty-eight attacks of chorea were in patients who had shown other rheumatic manifestations. However, twenty-nine of these sixty-eight attacks occurred when the rheumatic process appeared quiescent. The remaining thirty-nine attacks of chorea were accompanied by frank manifestations of rheumatic activity. All of which indicates that one half of all cases of chorea in New York may occur in individuals who are not susceptible to rheumatic fever. Choreic children of this type developed no stigmas of rheumatic disease, although each experienced from one to five attacks of chorea. These individuals did not have a familial history of rheumatic fever. Their attacks were not preceded by respiratory infections but seemed to be associated with psychic trauma. Their blood sedimentation rates and leukocytic counts were usually normal.

**Leukemoid Response of Tuberculous Rabbits to Tuberculin.**—To obtain experimentally a leukocytic response comparable to the so-called leukemoid reaction described as occasionally associated with tuberculosis in human beings, Feldman and Stasney observed eleven tuberculous rabbits. The hematologic observations were restricted to the quantitative and qualitative characteristics of the leukocytes. The results indicate quite definitely that tuberculin given to sensitized rabbits provokes an elevation of the leukocyte count, which is often of striking proportions. This increase is predominantly granulocytic and there occurs a marked shift to the left. The definite hyperplasia of the bone marrow, mitosis of the immature myeloid cells of the peripheral blood and other significant changes suggest a condition similar to the "leukemoid" reaction. The monocytes participate in the leukocytosis rather insignifi-

cantly, whereas the lymphocytes show a definite tendency to diminish in number during the reaction that follows the administration of tuberculin. Tuberculin given to nontuberculous rabbits has no significant effect on the leukocyte count.

**Preliminary Pain in Coronary Thrombosis.**—Feil believes that in about 50 per cent of patients the attack of coronary thrombosis is preceded by angina, unrelated to effort or emotion. He has seen fifteen cases with substernal pain preceding the onset of the severe symptoms by hours or days. Substernal or epigastric (rarely precordial) pain is complained of—mild, not related to effort or emotional strain, not severe enough to confine the patient to bed and often not severe enough to lead the patient to consult a physician. This pain is more or less constant, is of a burning and oppressive character and is not relieved by rest or by nitrites. The pain lasts from a few hours to four weeks. If the physician is consulted, he finds no change in the objective symptoms—the blood pressure is unaltered and there is no fever or leukocytosis. The heart sounds are unchanged. After a variable period of preliminary pain, the clinical picture of acute coronary thrombosis suddenly makes its appearance and with it the typical electrocardiographic changes. This preliminary pain occurred in approximately 50 per cent of the cases of coronary thrombosis observed in the last two years. The nature of the preliminary pains was suspected in three of the fifteen cases.

**Coronary Sinus Outflow as Criterion of Coronary Reactions.**—By recording the velocity of coronary sinus flow, returned at once to the superior vena cava, and by calculating the flow per beat and per minute, Johnson and Wiggers observed that the coronary sinus normally empties into the atrium only during systole, that increasing the right ventricular pressure by compression of the pulmonary artery—the heart rate and aortic pressures remaining the same—causes a proportional augmentation of coronary sinus flow, and that the increase in minute flow following only slight elevation of systolic right ventricular pressure is of the same order of magnitude as that frequently reported from stimulation of cardiac nerves or actions of drugs. They present a theory, supported by experiments, that the division of coronary return flow between coronary sinus and thebesian veins is determined not only by the anatomic resistance of these respective paths but by the height to which right ventricular pressure rises during each systole. This accounts for the proportionally larger flow from the coronary sinus in normally beating hearts and the greater drainage by thebesian vessels in dead hearts. It proves that a greater coronary sinus flow can occur through secondary increase in right ventricular pressure alone. Inferences regarding vasomotor actions in the coronary system based on alterations in coronary sinus outflow cannot be accepted as crucial unless it is demonstrated that right ventricular systolic pressure remains unchanged.

- Local Anesthesia in Abdominal Surgery. V. J. Kinsella.—p. 785.

**Routine Wassermann Test.**—From March 1933 Hughes and Gammie performed the Wassermann test on every patient as part of the routine antepartum examination, irrespective of age, parity or social position. In all, 3,404 patients were tested, 3,016 of the tests being true routine tests. The remaining 388 are from another outpatient day and are a routine test on all primiparas. Among the 3,016 patients who were submitted to a routine test the Wassermann reaction was found to be positive thirty-two times, or in 1.06 per cent of patients. When the incidence in multiparous and primiparous women is calculated, it is found that in the former it is 1.31 per cent and in the latter 0.47 per cent. A fact elicited in the investigation was the utter lack of previous history, which might have given a clue to the possibility of a positive result; in other words, if the test had not been done as a routine, but only in suggestive cases, the majority of cases would have been missed, especially in those multiparas whose previous pregnancies had been normal. That is, ten out of twenty-four multiparas with a positive Wassermann reaction had no history of miscarriage, premature labor, neonatal death or stillbirth, infection occurring apparently after the birth of the last child or not showing up in the children till a later date and thus giving a misleading history. The fact remains, however, that these cases will not be detected unless a Wassermann test is carried out as a routine procedure.

**Coronary Infarction in Young Adults.**—May reports four cases (in persons aged 19, 20, 39 and 38 years) which according to clinical investigations present the symptom complex associated with coronary thrombosis. All the ordinary known causes of changes in the T wave and the like could be excluded in these cases. The one condition about which there could reasonably be some duibety is acute rheumatic fever. None of these patients, however, fitted in with a picture of acute rheumatic fever. The argument, therefore, is advanced that the patients under discussion have on some previous occasion suffered from a rheumatic infection which has impaired the coronary circulation in certain limited areas. If the infective processes associated with rheumatism can cause sclerosis of a valve, then in view of the postmortem changes observed in rheumatic fever hearts it can be argued that such changes (venous thrombosis, periarteritis and adventitial infiltration) in a milder infection can cause sclerosis and deformity of limited areas of the coronary circulation. The analogy with the case of mitral stenosis in which the infective processes have been arrested would also explain why many of these cases show no further symptoms. It may also explain the etiology of many of the cases of coronary thrombosis occurring in the fourth and fifth decades in which it is difficult to find any other evidence of arteriosclerosis. The argument, therefore, is put forward to explain the symptom complex, as described in young persons, which in all other ways conforms to the accepted description of an attack of coronary thrombosis. Another possible explanation of these cases is the theory proposed by Leary: The presence of coronary sclerosis in young persons is due to an atherosclerosis, and these lesions arise from the entrance of lipoids into the subendothelial layer of the intima and their phagocytosis by cells referred to as lipid cells.

- Problem of Duodenitis. Gubergritz and E. Tchayka.—p. 1158.
- Diabetes Improved During Progressive Development of Pulmonary Tuberculosis. L. Szyfman and I. Lebowicz.—p. 1172.

**Shock in Treatment of Diseases of Digestive Apparatus.**—Ryss states that a whole series of factors sensitize the gastric cell. They modify its process of reaction and displace the threshold of irritability quantitatively and qualitatively. In other words, they make it "allergic." Allergy provoking factors are toxic and chronic infections, heterogenous and endogenous poisons under certain favorable conditions which are the result of a chain of events: in the vegetative nervous system, nervous trophism and activity of superior nervous centers. The anaphylactic reaction is primarily a cellular process; proteolysis, colloidoclasia in the plasma and in the tissues and also nervous disorders assume an important rôle. The author states that 65.5 per cent of the gastric and duodenal ulcers are of an allergic nature. There exists a local allergy of the gastric tissues. If the tissue is hyperergic, the pathologic reaction manifests itself in the shape of an inflammation which may have the characteristics and, as a nosologic unit, the symptoms of purely mechanical factors. Certain forms of enterocolitis are likewise of an allergic nature. The intestinal inflammation presents itself as mucous catarrh, fibrinous, necrotic and ulcerous forms (processes of fermentation or putrefaction). These disturbances modify the intestinal milieu, its bacterial flora and the antigenic properties of its bacteria and protozoa. In treating allergic disorders of the digestive tract the author uses the shock therapy by means of hemoprotein. However, the shock does not always communicate to the organism an immunity and a permanent desensitization. The shock therapy acts on the injured cell by bringing forth a hyperergic inflammation ending in cicatrization. The choice of the antigen is regarded as important, but the author fails to state his procedure in order to "obviate the repetition of the treatment." He looks forward to future treatment of allergic disturbances of the digestive tract, aware of the complexity of their pathogenesis.

## Bull. et Mém. de la Soc. Méd. des Hôpitaux de Paris

52: 1653-1684 (Dec. 21) 1936. Partial Index

- \*Severe Nervous Accidents and Profound Disorders of Dextrose Regulation in Children. R. Debré, J. Milhit, J. Marie, D. Nachmansohn and P. de Font-Réaulx.—p. 1653.

- Professional Oxycarbonemia. M. Loeper, E. Gilbrin and F. Signier.—p. 1671.
- Endogenous Oxycarbonemia. Loeper, Bioy, Gilbrin and Tonnet.—p. 1676.

**Accidents of Dextrose Regulation.**—Debré and his colleagues call attention to a type of nervous disorder characterized by unusual symptoms. It was observed by them in a child aged 3½ years. The child was in coma, which lasted several hours and was accompanied by abolition of the tendon reflexes and a bilateral Babinski sign. On regaining consciousness, the child was agitated, trembling and not prostrated as is a child recovering from an epileptic attack. She again entered a profound state of coma with abolition of the reflexes. The acetone odor of the breath was noted and resulted in an examination of the urine. The Legal test was strictly positive, but there was neither sugar nor acetic acid. On recovering from these nervous crises, clinical examination was totally negative. No organic disorder was demonstrated. The child was submitted to case study and examination and it was found that the trouble was due to lack of equilibrium in the dextrose regulation. This seemed to be allied to a neuro-endocrine disorder involving the nervous centers and the glands that control the harmonious metabolism of carbohydrates. It did not seem possible to explain the morbid phenomena by a single organic lesion or by deficiency in the production of a single hormone. From a practical standpoint it must be remembered that the presence of acetone and even dextrose in the urine does not indicate the treatment of an infant with insulin before

they could be demonstrated by roentgenograms or other phases of the examination. These subjects are grouped on the basis of the tuberculin reaction, the type of lesion that subsequently developed and other factors. In their experience adults in whom the first infection type of tuberculosis develops, even with considerable involvement of the pulmonary parenchyma and regional lymph nodes, do not require treatment in any form. The prevention of tuberculosis of the first infection type among young adults consists in protecting them against exposure to patients with communicable tuberculosis. For students of nursing and medicine this amounts to a strict technic for dealing with contagious diseases. When the first infection type of disease occurs in the second and third decades of life, it is just as benign as when it occurs in childhood.

**Pathogenesis of Erythema Nodosum.**—Spink gives data which indicate a causal relationship between *Streptococcus haemolyticus* and erythema nodosum: In five of the ten patients that he observed, erythema nodosum was preceded by a sore throat, and cultures in four cases revealed *Streptococcus haemolyticus* of the beta type; intradermal injection of a streptococcus endotoxin (nucleoprotein) produced nodules similar to the lesions of erythema nodosum in eight of the ten patients; excised streptococcal nodules and the lesions of erythema nodosum showed the same histologic appearance, and similar lesions were produced by the injection of broth filtrates of streptococci isolated from two of the patients. The same picture has been produced by the injection of tuberculin. An analysis of the records of 133 patients treated for erythema nodosum at the Boston City Hospital from 1924 to 1934 revealed a similar causal relationship to streptococcal infections and, in addition, to rheumatic fever. Erythema nodosum appears to be a non-specific inflammatory reaction of the skin to a variety of bacterial, toxic and chemical agents.

**Subungual Neuromyo-Arterial Glomus Tumor of Toe.**—This cites a case of senile arteriosclerotic circulatory disease in which normal thermocouple temperature readings followed treatments with alternating positive and negative pressure. After complete relief was obtained from the subjective symptoms, an excruciatingly painful and tender bluish pea-sized tumor was discovered protruding from beneath the right first toe-nail. This nodule had not been noticed previously. Histologic examination of the tumor confirmed the diagnosis of a subungual glomus tumor. In a review of more than 1,400 reported cases of peripheral circulatory disease in which alternating positive and negative pressure therapy was employed, no other glomus tumor was found.

**Hemangioma of Tendon or Tendon Sheath.**—On the basis of a review of all types of tumor of a tendon, Harkins concludes that hemangiomas of a tendon or tendon sheath comprise only a small proportion of tumors of such origin. His study of twenty-four such cases, including a personal case, reveals that in nineteen instances in which the sex was stated there were twelve women and seven men. The side on which the tumor occurred was stated in eighteen instances, the left being involved ten times and the right eight times. This does not indicate the marked preponderance of left-sided involve-

ment mentioned by Burman and Milgram. The upper extremity was involved thirteen times and the lower seven times. This is in opposition to the selective localization of hemangioma of the muscle in the lower extremity, as noted by Jenkins and Delaney. Observation of change in size on elevation and depression of the limb and after application of a constrictor is of importance in the diagnosis. Roentgen examination, as in the case of hemangioma of the muscle, will often reveal multiple calcified phleboliths. Positive results in this regard were reported in five of the twenty-four cases, as well as in Bouquet's case of hemangioma of a muscular aponeurosis. In only one instance were no phleboliths found on roentgen examination. Pathologic examination, as in the case of hemangioma elsewhere in the body, cannot always clearly differentiate between the predominance of endothelial, of fibrous and of hemangiomatous involvement. Likewise, the line of demarcation between lymphangioma and hemangioma and also between capillary and cavernous hemangioma must often be arbitrary. Three definite recurrences are mentioned, as well as two instances in which the operative removal was possibly not complete. Surgical treatment seems to be fairly efficacious, although many of the reported cases were not followed long enough to rule out recurrence.

**Effects of Trauma to Kidney.**—Colston and Baker discuss a series of thirteen cases, in all of which clinical examination or operation has revealed definite pathologic changes either in the kidney or in the perirenal tissue. The patients had been severely injured in the region of the kidney, at varying intervals of time before the patient was seen. The definite relationship of the trauma to the conditions described in these cases has been established, the conditions encountered varying from those causing minimal disability to those causing complete incapacity. The surgeon should be completely familiar with what changes may occur in the kidney or perirenal tissue as a late result of the injuries and should take the proper steps to prevent their development. All patients in whom injury to the kidney is suspected should be studied with special reference to the demonstration of persistent perirenal extravasation. It should be easily recognized by a palpable mass or the obliteration of the outline of the kidney and shadow of the psoas muscle on roentgen examination. In patients in whom hematuria has occurred as a result of an accident, an injury to the pelvis or calices should be suspected, and subsequent pyelographic studies should be carried out to make certain that distortion or particularly obstruction has not occurred as a result of the formation of scar tissue that may lead to subsequent serious damage to the kidney.

**Anxiety Syndrome Confused with Hyperthyroidism.**—Billings asserts that, during the last two years, one out of every twenty-one of the new adult admissions to the Colorado General Hospital and Dispensary was referred to the psy-

the coagulation time. The bleeding time is almost unchanged. The coagulation time increases early and intensely. Lesions of the liver parenchyma, diminished fibrinogenesis, changes of the calcium metabolism and toxic general conditions due to absence of bile in the intestine are the causes which alone or in association induce increase of the coagulation time. The latter is not favorably modified by administration of coagulants from blood platelet extracts. It diminishes transiently by administration of calcium salts and by blood transfusion. The transient results of calcium and roentgen treatments show that they have only a substituting action. Roentgen irradiation of the liver or of the hypogastric regions shortens the coagulation time for a period longer than that induced by calcium and roentgen treatments. It seems advisable to give roentgen irradiations over a region of the abdomen in order to shorten the coagulation time in jaundice. The results of the author's experiments show that the removal of the obstacle to the passage of bile into the intestine is the causal treatment of the disturbances of coagulation in mechanical jaundice. The coagulation time returns to normal, without further changes, as soon as the passage of bile into the intestine is reestablished.

Diagnosis of Multiple Myeloma by Sternal Puncture. A. Ferrata and E. Storti.—p. 1.

\*Histopathologic Study of Carotid Glands. G. M. Rasario.—p. 4.

**Histologic Study of Carotid Glands.**—Rasario studied the histologic and nervous changes of the carotid glands on cadavers of men who died from various diseases at different ages. The carotid glands were found in all cases, regardless of age. Both glands were removed. One of the glands was subjected, after fixation, to the De Castro-Cajal silver impregnation method for the study of the ends of the nervous fibers. The other gland was stained, after fixation, for study of the cellular alterations. The latter as a rule are of lesser importance. They consist especially in proliferation of the connective tissue and small cell infiltration. Alterations of the parenchymal cells cannot be noticed (perhaps because of the early changes of the glandular parenchyma after death). Senile sclerosis of the carotid glands begins at the age of 60 and is obvious at 70, with exceptions, however, because there are cases in which the glands are well preserved after 70. There are two types of cells in the parenchyma of the carotid glands: Cells with large hypochromic nuclei exist in the glands of young persons, whereas cells with dark, round, small nuclei are present in the glands of the elderly. The structure of the specific cells of the carotid glands indicates that the glands have secretory functions which, up to the present, have not been proved. The alterations of the ends of the nervous fibers of the glands are also of lesser importance and probably do not prevent the functions of the gland. According to the author, the carotid glands are not rudimentary, accessory or involutive structures but organs with definite functions which form a part of the depressive vasosensorial system of the carotid sinus.

New Technic for Preparation of Sheep Erythrocytes for Wassermann Reaction. A. Frates.—p. 170.

Spontaneous Amputation of Appendix: Case. G. Cardì.—p. 173.

**Ascoli's Treatment in Malaria.**—Cicchitto reports satisfactory results from Ascoli's treatment (intravenous injections of epinephrine) in malaria. Epinephrine is given in increasing doses of from 0.02 to 0.1 mg. The first two days it is given in association with 0.5 Gm. of quinine, in intravenous injections. An intravenous injection of epinephrine and an intramuscular injection of quinine, of the same amounts as those administered in the morning, are given at noon in severe cases for the first two days. The third morning the patient is given 0.5 Gm. of quinine by mouth and the intravenous injection of epinephrine. The noon treatments are discontinued. From the third day on, administration of quinine is discontinued. Intravenous injections of increasing doses of epinephrine are continued up to com-

pletion of six or eight injections, one every morning, besides those which are administered at noon in grave cases. The author succeeded in controlling many cases of malaria with visceral, digestive, hepatic circulatory, nervous, adrenal, sensorial and sympathetic complications. There are no recurrences or reinfections after the treatment, which has the advantages that quinine resistance is controlled, the dose of quinine given to the patient can be diminished, the disease evolves to rapid recovery and the development of posttropical benign malaria is prevented.

### Beiträge zur klinischen Chirurgie, Berlin

164: 513-672 (Dec. 23) 1936. Partial Index

Urographic Diagnosis of Renal Tumors. W. Staehler.—p. 513.

\*Hereditary Character of Neurofibromatosis of von Recklinghausen. C. H. Schröder.—p. 563.

\*Value of Indirect Roentgenologic Signs in the Diagnosis of End Tumors. H. Hellner.—p. 573.

Amniotic and Hereditary Nature of Flatfoot. C. H. Schröder.—p. 619.

Treatment of Dislocation Fracture of Capitellum Radii. E. Madern.—p. 628.

**Hereditary Character of Neurofibromatosis.**—According to Schröder, the multiplicity of symptoms of von Recklinghausen's disease is simplified by the grouping proposed by Ferdinand Curtius, according to which all its manifestations are divided into three groups: (1) multiple skin tumors (fibromata mollusca) frequently associated with nerve tumors, (2) anomalies of pigmentation of the skin, particularly smaller or larger pigmented nevi referred to as coffee spots, and (3) psychic disturbances, particularly imbecility, more rarely psychoses and psychopathies. Among other symptoms are mentioned skeletal changes, kyphoscolioses, asymmetries of the skull, thickening or rarefaction of bones and subperiosteal cysts. The bones may undergo decalcification or an abnormal increase in calcium. Pseudarthroses are noted in childhood. Another peculiarity is a keloid-like hypertrophy of scars, while disturbances of the glands of internal secretion may lead to hypogenitalism, acromegaly, myxedema, hyperthyroidism and Addison's disease. The histologic study of the multiple tumors reveals that they are neuromas, neurofibromas or pure fibromas. The origin of these tumors is to be seen in faulty differentiation of mesenchymal tissue from the ectoderm. The embryologic origin of the disease is indicated by its hereditary character. Of the 466 cases reported in the literature, a hereditary character was present in 18 per cent of the children and in 16 per cent of the adults. The author reports an observation of a family in which the hereditary transmission of the dominant type was traced for three generations. A father and twin sisters exhibited pigment anomalies and characteristic tumors confirmed by histologic examination. Four other members of the family exhibited an abortive type of the disease in the form of typical pigmentation anomalies of the skin; namely, the so-called coffee spots. One case presented an unusual location of a tumor under the tongue. Two cases of imbecility were present in relatives. Seven of the affected persons showed similar anomalies of pigmentation, while three showed rather large single tumors. Similarity of the symptoms and of the development of the disease suggests the existence of a familial type of the disease.

**Signs of Brain Tumors in Roentgenogram of Skull.**—Diagnosis of brain tumors must answer three questions: the location of the tumor, the size of the tumor and its nature. According to Hellner, the usual roentgenogram of the skull is capable of contributing important information to these queries. The knowledge of the alterations caused by tumors and visualized in an ordinary roentgenogram of the skull, while not as important as the neurologic examination and the knowledge of the course of an individual tumor, is nevertheless of considerable value. The author cites Kornblum, who found in 446 cases of brain tumor confirmed by operation or at necropsy that 6.5 per cent showed calcification. The intracranial tumors exhibiting bone formation were, in the author's experience, principally parasagittal meningiomas, neurinomas and cholesteatomas. Here the roentgenogram furnishes information as to the localization, the size and, to some extent, the nature of the tumor. The author describes localized hyperostoses of the vault and the base of the skull. These were likewise observed principally in meningiomas and occasionally in neurinomas and in neurinomas of the acoustic nerve. The roent-

and early fall. The results indicate that banana powder or pulp may receive favorable consideration in the treatment of those intestinal upsets occurring during the summer and fall months in infants and young children. The greater percentage of success was found in the older group of children. A much greater success was had even with the youngest infants with the banana therapy than with the accepted methods of treatment. Banana pulp therapy gave even better results than the banana powder. The patients of this group were in the outpatient department and were able to be taken care of at home, which does not give one as fair a comparison as do the hospitalized groups, who were more adequately under control and observation. But this treatment is just as efficient as the banana powder therapy, if not more so.

**Gentian Violet Treatment of Leg Ulcers.**—Thurmon and Chaimson believe that any therapeutic measure that may be proposed for the treatment of ulcers not only should aim at correcting an impaired vascular balance but also should possess bactericidal properties and an ability to control excessive granulation and, at the same time, should not injure the tissue cells. Gentian violet in 2 per cent aqueous solution is an agent possessing these qualities. Its use as a topical application in fifteen patients with chronic leg ulcers forms the basis of the authors' study begun Jan. 11, 1934. A topical application of the solution was applied from three to five times the first day, the patient being instructed to repeat this procedure through the following two or three days or until a hard, firm, dry, adherent crust had formed. With each application the solution was permitted to air-dry and at no time were the ulcers bandaged. As long as the violet-stained crust remained firm, dry and adherent it was not disturbed. Should any portion of the crust become loose or pocketed, that portion of the crust was removed with sterile forceps and scissors, the ulceration cleansed with dry sterile gauze and gentian violet reapplied as previously directed or until a new dry crust had formed. Loosening of the crust or pocketing beneath it is usually due to a collection of thin gray purulent material beneath the crust. During the entire period of treatment each patient remained ambulatory. With the exception of the edematous type of ulceration, treatment with 2 per cent aqueous gentian violet solution resulted in progressive healing. Pain and irritation materially subsided after the third or fourth application and usually disappeared after the first two or three days. Similarly the exudate from secondary infection was controlled within a short period of time. Once a firm, dry, adherent crust had formed, no reinfection occurred. Epithelization took place satisfactorily. Complete healing of all ulcers occurred in from eight weeks to seven months. The resulting scars were thin and flexible and in some instances difficult to distinguish from the surrounding

normal skin. With the edematous ulcers the results were unsuccessful until the edema was brought under control. Topical application of gentian violet during the edematous stage was ineffective, since the stain was diluted or completely washed away by the serous exudate. Whenever it was possible to control the local and surrounding edema, the gentian violet treatment was of definite aid in hastening healing.

**Carbohydrate Meal Instead of Fat Meal in Cholecystography.**—Believing that dextrose must have some advantages over fat, Kestel used a carbohydrate meal instead of the usual fat meal when relatively faint shadows were obtained. Two hours later a slightly smaller but considerably denser gallbladder shadow was obtained in each instance. This procedure was then adopted as a routine to replace the fat meal. In fourteen of thirty cases a heavier, smaller shadow was obtained after the carbohydrate meal. In eight cases the shadow was as intense, although reduced in size. Of the remaining eight cases, two showed little change in the shadow, in three it was smaller and fainter, and in the remaining three it had disappeared completely. In one instance a shadow was visualized after the carbohydrate meal when it had not been present before. While the results have not been perfectly uniform, it is certain that the procedure has advantages. With the smaller shadow of relatively increased density, stones or other negative shadows might be discovered when overlooked in the original roentgenogram. For a person of average weight a meal at noon devoid of fats is followed in thirty minutes by 2.5 Gm. of dye. The evening meal at 6:30, consisting largely of carbohydrates, is again followed by 2.5 Gm. of dye. Fruit juices are allowed during the first hour after either administration of the dye. The first roentgenogram is taken the following morning at 8:30 and is followed by a carbohydrate meal. This meal consists of two slices of toast with jam or jelly, a glass of orange juice, and either tea or coffee with sugar. The second and last roentgenogram is taken two hours later. Patients with faint or absent shadows are given the carbohydrate meal and it is repeated two hours later. If the patient has vomited part of the dye or developed diarrhea and the carbohydrate meal fails to intensify the shadow adequately, the cholecystograph is repeated after the intravenous administration of the dye. A second roentgenogram is again taken two hours after a carbohydrate meal. If there is any question of slight motion, another roentgenogram is taken. In the small number of cases examined by this method, no errors have been detected.

an infection of the blood stream, from which the infection was carried in one of the patients to the lung, kidney and brain, and in the other patient to the right cerebral hemisphere, lung, frontal sinus, skin and endocardium. Regarding the location of the primary focus, only suppositions are possible. In the first patient there were indications that it might have been in the intestine, in the second patient in the tonsil.

### Late Postmortem Demonstration of Carbon Monoxide.

—Pieczarkowski states that the literature on death by asphyxiation from illuminating gas is scanty from the medicolegal point of view of demonstrating the cause of death after exhumation of the suspected body. His experiments show that: 1. Demonstrating death from illuminating gas by means of spectral and chemical analysis of the blood and the edematous condition of the exhumed organs was easy after two months. 2. In atelectatic and decomposed parts of the body illuminating gas has been demonstrated even after two and one-half years. 3. If a vessel is filled to the top with blood poisoned by illuminating gas and is sealed air tight, the positive presence of illuminating gas may be demonstrated after twenty years (and even for a much longer time) by chemical and spectral analysis. 4. During one year illuminating gas in the blood may be demonstrated by pouring thickly and drying the blood in a porcelain dish or in a watch glass. 5. If the blood is poured in a vessel which it does not fill completely, and is sealed and shaken so that the air left in the vessel is mixed with the blood, the illuminating gas cannot be demonstrated any more after one month. 6. It can be found for twice as long (fifty-five days) when the vessel has not been shaken. 7. The blood left in an uncovered vessel shows the presence of illuminating gas for about two weeks. 8. If the blood is regularly stirred with air, the illuminating gas is lost in about five hours. 9. The blood mixed with Jäderholm's solution shows illuminating gas for only a short time.

### Parenteral Liver Therapy in Sinus Thrombosis.—

Engelkes, after citing the decrease in rapidity of the blood current and changes in the endothelium and in the blood as the factors that play a part in the pathogenesis of thrombosis, points out that several authors observed that the injection of liver extract exerts a favorable influence on the course of post-operative thrombosis and thrombophlebitis. He describes the histories of two patients with sinus thrombosis, one of whom had the "spontaneous" and one the suppurative type. In both of these patients he resorted to the intramuscular injection of liver extract, giving 2 or 3 cc. twice daily and continuing the injections for two weeks. Later the liver was given by mouth. Both patients recovered. The author concludes that in operative as well as in nonoperative cases of sinus thrombosis injections of liver extract should be given for about a week, eventually followed by oral medication.

### Phosphorus Lipoids in Blood of Patients with Cancer.

—Gezelle Meerburg points out that the phosphorus lipoids or phosphatides, the chief representative of which is lecithin, play an important part in the organism. He reviews the reports of other investigators, such as Marsman's study on the lipid content of the blood of patients with tuberculosis, and then

reports his own studies on twenty-nine cancer patients and on three with other chronic disorders. All the patients were rather undernourished. Tabular reports show that the values varied between 4 and 11.7 mg. per hundred cubic centimeters of blood. In the men the average value was 8.05, in the women 7.62 mg. per hundred cubic centimeters of blood. The author thinks that the undernourished condition influences the phosphatide content of the blood.

**Blood Pressure Reducing Substance.**—Wollheim demonstrates that the urine of normal subjects and of horses contains a blood pressure reducing substance. The urine of patients with essential hypertension is either entirely free from the substance or it is present in only small quantities. The author describes the chemical and physical behavior of this thermostable substance. It is well characterized and readily differentiable from other blood pressure reducing substances by its behavior during boiling with acid and lye and toward the usual solvents and precipitants and by the use of dialysis and electrolysis. A blood pressure reducing substance that is essentially the same can be extracted from the posterior lobe of the hypophysis. The physiologic action of the substance that is extractable from the urine as well as from the posterior hypophysis consists in a considerable dilatation of the peripheral vessels. Its blood pressure reducing effect persists for comparatively long periods and in this respect it differs from all formerly known blood pressure reducing substances. Pure preparations do not influence the heart, the respiration or the intestine. The intramuscular injection of the substance reduces the blood pressure of patients with essential hypertension.

**Edema of the Temples in Thyrotoxicosis.**—Wahlberg describes six cases of edema of the temples in thyrotoxicosis. The edema appeared at the height of the disease or when the other symptoms were subsiding and, as a postoperative symptom, simultaneously with myxedema or during seemingly normal thyroid function. In one case it seemed to be an early symptom of the disease. He discusses the pathogenesis of the eye symptoms in thyrotoxicosis, especially the exophthalmos and the edema of the eyelids.

**Disturbances in Plasma Proteins and Bone Marrow Therapy.**—Ehrström points out that quantitative and qualitative changes in the plasma proteins are quite common. In infections of various types, particularly chronic suppurations, tuberculosis and syphilis, the globulins are increased. Multiple myeloma is usually accompanied by an increase in the total amount of proteins; here too the globulins are usually the chief factor. The hyperproteinemia that is due chiefly to an increase in the albumins is often present in essential hypertension. Hypoproteinemia is even more common than is an increase in the plasma proteins. In this connection the author mentions nephritis, starvation edema, pernicious anemia, myeloid leukemia, cardiac insufficiency, cirrhosis and atrophy of the liver, diarrheas and so on. He reviews what is known about the localization and the manner of production of the plasma proteins, pointing out that investigations in recent years have disclosed that changes in the plasma proteins concur with pathologic processes in certain cells of the bone marrow. After making a comparison between the plasma protein metabolism and the hemoglobin metabolism, he reports a case of hypoproteinemia in which the plasma proteins remained practically the same during nine months of treatment with liver and a diet that had a high protein content. However, when thereafter treatment with a bone marrow extract was continued for only a month, a considerable increase was produced, which involved only the albumins.

\*Estimation of Coagulation Time of Blood: Simplified Method. H. Trought and J. W. Riddoch.—p. 1194.

**Cirroid Aneurysm of Scalp.**—Clunie points out that the etiology of cirroid aneurysm of the scalp does not appear to have been settled. An attractive theory is that cirroid and racemose aneurysm, the aneurysm of anastomosis and the pulsating angioma are due, as is arteriovenous aneurysm, to an abnormal communication between the arterial and venous systems and that such a communication may be either developmental or traumatic in origin. Even large cirroid aneurysms of the scalp may be extirpated by a method which depends for its success on the easy stripping of thrombosed and edematous tissue, including the aneurysm, from the skin layer of the scalp flap. Despite the fact that the vascular layer is stripped from the flap with the aneurysm, the skin flap receives sufficient nourishment and but little sloughing takes place even with a large flap. In the case described the whole aneurysm was excised. Seaby, dealing with a larger aneurysm, excised only two thirds of it and the results were excellent, because the abnormal communication between the arterial and venous systems was abolished. An interval of ninety-six hours between the two stages of the operation should not be exceeded, as necrosis of the flap edges might occur. The operation should not be a formidable one in practiced hands, despite the vascularity of the scalp; hemorrhage will naturally be greater and the operation time will be longer if aneurysmal tissue has to be cut through.

**Blood Transfusion.**—Plummer stresses the risks of transfusion that are dependent on the condition of the recipient. He reports six fatal cases: 1. A case of Addison's anemia in which pulmonary edema developed after transfusion and death occurred in ten hours. 2. In a case of gastric carcinoma with moderate anemia, death took place nineteen hours after transfusion. 3. In a man of 72 with multiple telangiectases and severe anemia, death occurred four hours after transfusion. 4. The fourth case was one of hemolytic anemia with mitral stenosis. After transfusion, pulmonary edema developed and death ensued in two hours. 5. Death occurred in half an hour in a case of chronic empyema after a second transfusion from the same donor. 6. The last case was one of esophageal ulcer with secondary anemia. The patient had had five previous transfusions with a hemolytic reaction and died four days later from uremia. Doubt is cast on the accepted theory of hemoglobin plugging of the tubules in all cases of uremia following transfusion. With all ordinary precautions of grouping and selection of cases, blood transfusion carried with it a risk which indicates that it has to be used with considerable discretion in a number of conditions.

**Estimation of Coagulation Time of Blood.**—In estimating the coagulation time of blood, Trought and Riddoch need one glass tube drawn out into a capillary tube open at both ends and a filter paper divided by pencil into segments from the center for receiving the drops of blood expelled from the tube. Blood is drawn up into the capillary tube by surface tension, and at minute intervals the end is placed in a slanting direction on to the segments of the filter paper. Before coagu-

lation the drop of blood is absorbed into the filter paper. After an interval varying from five to nine minutes for specimens of normal blood, a tiny thread of fibrin stretches out from the filter paper to the end of the capillary tube. The appearance of this thread of fibrin is taken as the coagulation time of the blood in question, and there is no possibility of mistaking the appearance of the fibrin thread in practice, so that uniform results can be easily obtained on repetition.

**Treatment of Obesity in Children.**—Mallam is convinced that dieting is the keystone to treatment in almost all cases of obesity in children, but before prescribing a system of diet a careful family history and knowledge of conditions under which the child is being reared must be obtained. Obesity beginning in childhood often gives rise to endocrine trouble later on, and when one finds a strong dominant obesity factor in the family one should always be prepared to face a more difficult task than in a purely fortuitous case arising from normal stock. Even then, however, a cure, permanent and complete, can be obtained in the majority of cases by simple measures. The treatment must be explained carefully to the child and need not be elaborate. A simple practice is to weigh and measure the child and give it a diet based on the calculated basal requirements for this particular height and size. This is merely a beginning figure, and it may be necessary either to add to or subtract from the initial starting point. The question of the fluid intake is of considerable importance. If these children are counseled to drink early in the morning and then to try not to drink at all through the day, this is often a great help in reducing weight. Appetite is largely a question of satiation and these children must be schooled to eat slowly. Salt and sugar should be cut down to a minimum. Many children appear even fatter than they are because of postural defects. Exercises devoted to training the recti abdominis and correcting any possible lordosis and to making them stretch their overloaded limbs are all valuable. Such exercises are always more effective under trained supervision and are usually better done in a class of several children. Some sort of abdominal support employed temporarily often gives considerable help. At the same time strengthening exercises are absolutely essential, for without them one must either rely on artificial means or face a serious chance of visceroptosis. If a child loses weight consistently under treatment, the treatment is being overdone. If one treats an overweight child of 10 years and at 12 the child weighs the same, one should realize that a great deal has been achieved.

## NEGRO EDUCATION

Our surveys showed a definite improvement in those few medical schools that are devoted to the training of Negro physicians; but there is much to be done if we are to ensure adequate medical care for some 11 per cent of our population, which is widely scattered throughout the nation and in which certain diseases, such as tuberculosis and syphilis, have a very high rate of incidence.

## COMMENT

Some physicians may wonder why such a report as I have just given comes from a council of the American Medical Association. Let us look back for a moment to the rôle which this association has played in medical education:

It is customary to refer the origin of the American Medical Association to a national convention of delegates from medical societies and medical colleges called in 1846 by the Medical Society of the State of New York, mainly through the efforts of Dr. Nathan Smith Davis, for the purpose of raising the standard of medical education, which was then in a deplorable condition in this country. A year later, in Philadelphia, a permanent organization was effected with the avowed objective, according to the preamble of the constitution, of "cultivating and advancing medical knowledge; elevating the standard of medical education; promoting the usefulness, honor, and interests of the medical profession; enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; exciting and encouraging emulation and concert of action in the profession; facilitating and fostering friendly intercourse between those engaged in it." The present constitution, adopted in 1901, has not materially modified this declaration of purpose; but in the light of the vastly increased importance of preventive medicine, the phrase "the broad problems of hygiene" has been substituted for "the duties, responsibilities and requirements of medical men" as the subject regarding which public opinion should be informed.

At the second meeting of the Association, in Baltimore, the Committee on Education reported on existing conditions and recommended, among other things, that greater care should be exercised in the selection of medical students. Unfortunately, the warnings of this committee and its successors were not heeded, and the Association had not at its command the resources with which to follow up the efforts of these pioneers.

Half a century later, under the leadership of Dr. George H. Simmons, the Association again tackled the problem of raising medical education from the deplorably low level to which it had sunk. First he secured from every school, if possible, a catalogue or published announcement of its program and by analysis of these statements was able to show what sort of a medical curriculum was offered, or at least claimed. With few exceptions he found that educational requirements for admission were practically nonexistent. In the laboratory branches trained teachers were rare, and in the clinical subjects teaching was almost wholly didactic. Opportunity for personal contact of student with patient in taking histories and making examinations was for the most part conspicuously absent.

Reports from state licensing boards revealed an excessively large number of failures, although the examinations of these boards were certainly not unreasonably severe.

These facts, reported in *THE JOURNAL*, led to the formation of the Council on Medical Education in order

that the current procedure for training and licensing physicians might be more adequately studied and that written reports might be supplemented by personal visitation. A permanent secretary was appointed, who visited the schools in the United States, reporting his observations to the Council. Two years later all schools were revisited and on the basis of these inspections were classified as A, B or C. Naturally, there was a strong reaction from the schools, and the Association was attacked as a "medical trust."

At this juncture the recently organized Carnegie Foundation for the Advancement of Teaching was brought into the picture. Mr. Abraham Flexner, a man of excellent academic training but with little knowledge of medicine, was employed to make a survey of medical teaching in this country. Accompanied by Dr. Colwell, he visited the schools and recorded his conclusions in the historic Carnegie Report. His criticism, more scathing than that of the Council, could not be discounted on the ground of professional jealousy, and trade union motives could not be attributed to the Carnegie Foundation. The report was accepted by the nation. Public opinion, deeply aroused, compelled a radical revision of the methods and standards of the medical schools and likewise of the state examining boards. In response to public demand, many states passed laws restricting the licensing examination to graduates of class A, or "reputable," schools.

Low grade schools could not exist if their graduates could nowhere obtain a license to practice; but, unfortunately, some states have been slow to adopt the measures necessary to safeguard the health of their citizens. In consequence, even after a quarter of a century some such institutions exist. Public opinion must be again aroused and crystallized in legislative action if all our people are to enjoy the benefits of modern medicine at the hands of properly trained physicians. To arouse and direct public interest, and particularly that of the medical profession, is the present duty of the Council.

It may be asked why the American Medical Association, a professional group, should have assumed responsibility for regulating the training of candidates for medical licensure. Is it not the function of the state to protect the lives of its citizens, and is it not the express purpose of the statutes governing medical practice to discharge this responsibility by excluding all those who have not satisfactorily demonstrated their competence by passing the examination of the state board? In theory this is true, but in fact no merely written examination can test the physician's skill. Only by confronting the candidate with a series of patients can one learn whether he is able to make the requisite examination of the patient and from his observations draw reliable conclusions. Such examinations cost money, and as yet no state has made appropriations to defray the cost of its licensing examinations; the boards exist only on the fees which they can collect from examinees, which are nowhere sufficient to conduct the kind of an examination which would surely exclude the ignorant and incompetent. Having, then, no means of adequately discharging their responsibilities, the boards have necessarily sought elsewhere a method of safeguarding their public, and such assistance they have found in the classification of medical schools by the American Medical Association. Such boards as admit to the examination only the graduates of schools approved by the Council can at least be

verification of the level of blood sugar. Without this precautionary measure, hypoglycemic coma might be caused, possibly with fatal results.

- \*Sexual Function in Chronic Adrenal Insufficiency. G. Marañon.—p. 2057.
- Alimentary Equilibrium and Vitamins. R. Lecoq.—p. 2060.
- Coexistence of Two Recklinghausen Diseases in One Subject. R. Cohen and D. Douady.—p. 2063.
- \*Polyposis of Small Intestine. A. Mukbil Atakam.—p. 2065.

**Sexual Function in Adrenal Insufficiency.**—Many clinical observations have indicated that the adrenals, especially the cortex, exert a definite action on the sexual function. Marañon reports a further clinical and experimental study of this relationship. The majority of cases of Addison's disease begin after puberty; consequently it seems that the relation between the age of first menstruation and the disease cannot give important information. Nevertheless, a study of the age of onset of menstruation indicated that the puberty of women with Addison's disease begins on the average later than that of normal women. Furthermore, it was found that the proportion of cases of menstrual insufficiency in Addisonian women was especially high, which fact reinforces the hypothesis of the action of the adrenal hormone on the gonadal function. A large number of women with Addison's disease were infertile in a much higher percentage than healthy women of the same age groups. The proportion of abortions among the thirty-one Addisonian women was not higher than that of normal pregnant women. Pregnancy, however, in women later affected with Addison's disease was accompanied by a higher percentage of intoxications than normally. Mammary atrophy is also common in Addison's disease and furnished some evidence that the adrenal hormone exerts a stimulating effect on the breast. In the author's observations, symptoms of adrenal insufficiency did not seem to be especially aggravated during the menopause. A definite weakening of the sexual impulse in Addisonian men was frequently noted. The author believes that all these facts coincide with the experimental observations made on adrenalectomized animals and previously reported clinical observations.

**Polyposis of Small Intestine.**—According to Mukbil Atakam, polyposis of the small intestine is encountered rarely. Acute invagination of intestine is seen most often in nurslings and is relatively easy to diagnose. The chronic form, of insidious onset, is difficult to diagnose and less dangerous but is a disease of childhood and adolescence. It is rare in nurslings. The onset is sometimes acute, with periods of quiescence. The severe pain sometimes lasts several weeks. Vomiting is usual after a meal. Sometimes there is constipation and sometimes diarrhea, and sometimes alternation of the two. The general condition is changed from day to day. Recurrences are observed, with periods of quiescence, during which the child sleeps and gives hope of cure. These periods follow one another for a duration of a month to a year. Without surgical intervention the child dies from an occlusion or an intestinal invagination. Intestinal polyposis is dangerous from all points of view and especially from the standpoint of malignant degeneration. Once diagnosed, operation is necessary. Solitary polyps should be excised. Multiple disseminated forms should be resected with the intestine. General treatment must be administered and directed especially against anemia and inanition.

- Chronic Types of Poisoning. W. Heubner.—p. 45.
- Injuries on Tendons of Hand. W. Stahel.—p. 51.
- \*Some Experiences in Quantitative Determination of Alcohol Content of Blood. F. Schwarz.—p. 54.
- \*Treatment of Habitual Dorsal Luxation of First Metacarpus. K. Lenggenhager.—p. 58.

**Determination of Alcohol Content of Blood.**—Schwarz discusses the quantitative determination of the alcohol content of the blood and its significance in connection with motor vehicle accidents. In the living, it is best to examine the blood, for the results of the analysis of the urine are unreliable; however, after death, the analysis of the brain gives the most exact information about the amount of alcohol that has been

taken. The objection repeatedly is made that human subjects do not react to alcohol in a uniform manner, some persons being more sensitive to it than others and the same person being more sensitive at one time than at another. Nevertheless, the reliability of a method is determined by the practical experience with it. The author evaluates the results of alcohol analyses in more than 1,000 cases and reaches the conclusion that his results dispel any doubt as to the practical value of the quantitative alcohol analysis. He maintains that, if values of less than 0.05 per cent are found, the effect of alcohol cannot be considered a causal factor, for with such a concentration of alcohol the majority of persons show no signs of an acute effect of alcohol. If the concentration is between 0.05 and 0.1 per cent, the majority of persons are still free from the signs of alcohol intoxication, but in approximately one third of the cases, particularly in women and young persons, a concentration near 0.1 per cent causes signs of alcohol intoxication. Consequently, such values do not entirely exculpate a person, nor can they alone, without attention to the clinical signs, be considered a sufficient basis for legal evidence. Alcohol concentrations between 0.1 and 0.15 per cent are accompanied by signs of alcohol intoxication in 93.7 per cent of the cases, signs of excitation predominating over paralytic manifestations. Concentrations between 0.1 and 0.15 per cent are found most frequently in cases of traffic accidents, excessive speed and neglect of safety rules, as the result of the excitation caused by alcohol, being the usual causes of such accidents. Concentrations between 0.15 and 0.2 per cent are in the majority of cases accompanied by the signs of true intoxication in that paralytic symptoms are present, but some persons are in a state of excitation, some have already impaired consciousness and a few (2.3 per cent) still appear free from the effects of alcohol. The author thinks that in concentrations of 0.2 per cent and more it may be asserted that the person in question was incapable of coping even with comparatively simple traffic problems. He emphasizes that the withdrawal of the blood specimen should be made as soon after the accident as possible.

**Treatment of Habitual Dorsal Dislocation of Metacarpus.**—In the case reported by Lenggenhager a man, aged 23, in a fall on the left hand sustained a hyperflexion of the carpometacarpal joint and dorsal subluxation of the first metacarpus. The first reduction was effected without great effort, but the dislocation recurred and neither a plaster-of-paris splint nor a leather wristband counteracted the defect. After a surgical intervention had been rejected as useless by others, the patient came under the author's observation, who decided to resort to surgery. He exposed the capsule of the joint and found that the laxity of the formerly torn capsule was responsible for the habitual dorsal dislocation. After studying the mechanism of the dislocation on the exposed capsule, the author decided to secure the joint on both sides by means of sutures in such a manner that a dorsal dislocation of the metacarpus was made impossible. In a diagram the author shows where the sutures were fastened on the articular capsule. The skin was sutured and a volar plaster-of-paris splint was put on to immobilize the basal joint of the thumb. After six days the skin sutures were removed and after ten days the basal joint of the thumb was carefully mobilized. At the end of three weeks a small thread fistula had formed in the otherwise closed surgical wound. Five weeks after the operation the capsule suture could be pulled out and after another week the small fistula had closed. The function of the joint was almost normal and the patient was able to take up his occupation again. Examination four years later showed that the patient was free from trouble, but a slight grating was still perceptible on movement of the carpometacarpal joint.

**Experimental Mechanical Jaundice.**—De Blasi studied the behavior of the bleeding and coagulation time in experimental mechanical jaundice and the action of coagulants, blood transfusion and roentgen irradiations of an abdominal region on

out in 1933<sup>4</sup> that the occurrence of a secondary rise of pressure is beside the point clinically, as no one relies on a single dose of dextrose in a serious case. Later doses, at intervals of from four to six hours, can be relied on to overcome the secondary elevation along with the excessive pressure attributable to the trauma itself.

Rand,<sup>5</sup> discussing brain injury in 1934, wrote: "During the past decade, the use of hypertonic solutions, especially glucose, has become almost universal in treating cerebral edema." With reference to the secondary rise he stated: "Whatever physiological arguments can be brought forth, for or against its use, I am convinced that, since its employment, the necessity for decompressive operations has been greatly reduced." He further stated: "I believe that the use of glucose has saved many lives."

Davis,<sup>6</sup> as late as 1934, continued to recommend osmotic therapy by means of dextrose, and in his textbook,<sup>7</sup> published in 1936, he presents it as a standard treatment.

Numerous clinical papers of recent date could be cited to show that many surgeons continue to adhere to the hypertonic dextrose therapy in cases of brain injury. Apparently they are more persuaded by their clinical observations, which have been favorable on the whole, than by reports of adverse effects of single doses of dextrose given experimentally.

The present authors made use of intravenous dextrose in 50 per cent solution in a series of approximately 100 cases of brain injury and were convinced that it had a life-saving effect on many occasions. We came to the conclusion that there is little profit in withholding, in the face of threatened disaster, a therapeutic agent of known immediate efficacy merely because it may exert an adverse influence later when the patient may be better able to stand it. If the treatment of acute brain injury is conceived of as a race against time, any agent powerful enough to prevent impending death in crises should not lightly be discarded on the ground of delayed disadvantages, which are certainly not prohibitive, as has been proved by countless clinical experiences.

Not to our knowledge has any responsible proponent of osmotic therapy by means of dextrose ever recommended it as other than an adjunct to the management of brain injuries. It seems necessary to stress that brain injuries constitute a group of such varied pathologic features that correct treatment includes many other procedures than intravenous injections.

From our experience in the use of dextrose we came to recognize that dehydration therapy can be carried too far. The patient's water metabolism needs to be maintained at a level adequate for the elimination of nitrogenous wastes and in protracted cases blood chemical determinations should be used as a guide. We also learned that injections of concentrated dextrose can be badly timed. It is certainly wrong to give an intravenous dehydrating agent in every case of acute brain injury immediately on admission to the hospital. There is need to know by clinical signs or by spinal manometry whether the condition to be treated by the osmotic agent really exists. Therefore we came to value lumbar puncture, performed periodically and by a meticulous

technic, as a means of keeping informed of intracranial conditions, of gaining exact indications for administering osmotic treatment, and of assisting in the maintenance of intracranial pressures consistent with life.

The foregoing principles are pertinent to this report of our experience with osmotic therapy in brain injury cases, in which we used 50 per cent sucrose in place of dextrose. In osmotic therapy it is not only the agent that is important but the way in which it is used.

#### EXPERIMENTAL BASIS FOR SUBSTITUTING SUCROSE FOR DEXTROSE

Masserman,<sup>8</sup> in 1934, offered decisive evidence of the late rise of intracranial pressure to levels far higher than the initial ones following the intravenous injection of hypertonic dextrose solution in eighty-five human subjects whose brains were untraumatized. Bullock, Kinney and Gregerson,<sup>9</sup> using dogs, confirmed this relationship. In the same paper, citing the proof by Keith, Power and Peterson<sup>10</sup> of the rapid and almost quantitative excretion of sucrose after its intravenous injection, they reported marked reductions of cerebrospinal fluid pressures without secondary rise during a seven hour period, following the intravenous injection of from 3 to 8 Gm. of sucrose per kilogram of body weight.

Gregerson and Wright<sup>11</sup> found no significant increase in hydrolyzable carbohydrate in the cerebrospinal fluid after the injection of sucrose intravenously, establishing that the substance is unable to pass the blood-brain barrier, at least as far as the cerebrospinal fluid is concerned and in the intact brain. Dextrose, on the other hand, produced a marked glycorrhachia—a result consistent with the preponderance of evidence in a long standing controversy over the relation between blood and spinal fluid dextrose.

Bullock, Gregerson and Kinney<sup>12</sup> reviewed the whole subject very completely and reported additional animal experiments which confirmed their previous report of the efficacy of sucrose in producing large decreases of cerebrospinal fluid pressures without subsequent rise to pressures above the initial ones in twelve hours of observation. Usually the pressure, after a period of marked hypotension lasting about four hours, gradually rose to a level about 10 mm. (of Ringer's solution) below the initial one.

Finally, Masserman,<sup>13</sup> working with thirty-five human intact brains, found that doses of 300 cc. of 50 per cent sucrose produced falls of cerebrospinal fluid pressure as great as 50 mm. of Ringer's solution with no subsequent rise in many hours of observation. With doses of 500 cc. he noted falls of from 75 mm. to 150 mm., lasting from two to three hours. After the larger doses, transient and slight secondary increases to levels above the initial ones were occasionally observed. There were no toxic effects.

genogram furnishes information as to both the localization and the nature of the tumor in the case of meningioma. Histologic studies of meningiomas characterized by a tendency to form hyperostosis demonstrated invasion of bone by tumor cells. The roentgenologic and clinical differentiation of osteoma and meningioma no longer offers serious difficulty. One must be careful in interpreting erosions and atrophies of the skull. They can be caused by general increased brain pressure as well as by the direct pressure of a tumor. They do not furnish any definite evidence of a topographic, qualitative or quantitative kind. The value of roentgenologic signs in the diagnosis of the nature of tumors of the cerebellopontile angle is limited. On the other hand, the topographic diagnosis of tumors of the acoustic nerve is, as a rule, reliable. The size of the tumor cannot be told from a roentgenogram.

Experiences with Radium Treatment of Hemangiomas. H. Aretz.—p. 682.

**Short Wave Therapy Without Heat Effect.**—Liebesny says that the aim of the short wave therapy recommended by him is the opposite of that of diathermy. Whereas in diathermy a more or less intense heating is desired, the athermic short wave therapy avoids heating as much as possible. The author states that short wave therapy with excessive or moderate thermic action involves dangers. He shows the picture of a necrosis that resulted in a case in which relatively high doses were administered and in which the condenser electrodes had been in direct contact with the skin. To be sure, such burns do not result when the distance method is used, which was recommended by Schliephake and by the author. It is pointed out further that, in case of high thermic action of the short waves, tissue injuries may develop also in the deeper lying organs. Athermic short wave therapy exerts a biologic action. He cites examples which prove that short waves elicit biologic actions that are the opposite of heat actions. Finally he demonstrates that by athermic short wave therapy, that is, by excluding heat action as much as possible, favorable therapeutic effects can be obtained in suppurating and inflammatory processes on the surface of the body as well as in the deeper layers.

**Treatment of Cutaneous Cancers with Soft Roentgen Rays.**—Ebbelhoff points out that the biologic reactions will be the same with any quality of gamma rays, provided the distribution of rays within the tissue is the same. He cites reasons why it is desirable to replace radium rays with roentgen rays in the treatment of cutaneous cancer and describes his own efforts with extremely soft roentgen rays. He emphasizes that the rays he uses are not the ones which are usually designated as soft roentgen rays but are "extremely" soft. They are produced with tensions of less than 30 kilovolts and are so soft that, in order to obtain a sufficient quality from the tube, it is necessary to have a so-called Lindemann window melted into the tube. Their half-layer value in aluminum varies between 0.015 and 0.2 mm. and their half-layer value in the skin varies between 0.2 and 2 mm. After citing preliminary experiments on animals and tissues, the author describes his experiences on patients. First he employed borderline rays, which were produced with 12 kilovolts and had a half-layer value in the skin of 0.3 mm. The application of 6,000 roentgens in one session proved adequate in nonmalignant cutaneous growths, but from 8,000 to 20,000 roentgens was applied in patients with cancer. This mode of treatment was employed during 1933, 1934 and 1935 in seventy-two patients with nonmalignant growths, ninety-five patients with cancer and seventeen patients with doubtful growths. It was found that 20,000 roentgens applied with a tension of 12 kilovolts cured cutaneous cancers of a depth of 1 mm. In cases in which the cancer was deeper, the top was removed with a sharp curet and the bed

was irradiated. This procedure did not result in disfiguring scars. Later the author discovered that a slightly harder type of ray could be used successfully for cutaneous cancers of a depth up to 5 mm. These rays are of a quality that is determined by a tension of 25 kilovolts and a half-layer value in the skin of 1.6 mm., following filtration through 0.19 mm. of aluminum. With this type of ray, 5,600 roentgens is applied at once. This quantity can be administered in about eleven minutes. The author emphasizes that the treatment with extremely soft roentgen rays is simple, rapid and inexpensive.

**Blood Picture in Uterine Carcinoma.**—Goecke studied the hematic changes in 110 patients with uterine carcinoma before and after irradiation. He found that before the irradiation the reduction in the hemoglobin content is the greater, the more extensive the carcinoma. The erythrocyte values show a similar behavior. If the carcinoma is in the beginning stage, there is a slight increase in the leukocytes; if it is in a more advanced stage, the increase in leukocytes is more noticeable. During the beginning stage, this is not due to an increased production of granulocytes but rather to a stimulation of the lymphocytopoiesis. This is proved by the high numbers of lymphocytes in comparison to the slight degree of deviation to the left. In the unfavorable cases, however, the leukocytosis is a result of an increase in the neutrophilic cells. This can be deduced from the greater deviation to the left and the small number of lymphocytes. The author emphasizes that the influence of radium and roentgen rays on the blood picture in case of uterine carcinoma cannot be determined by simply comparing the blood status before and after the treatment, as has been done by other investigators, for it cannot be doubted that during the time of observation the blood picture is influenced not only by the irradiation but also by the carcinoma. Consequently, in comparing the blood changes before and after irradiation the author gave especial attention to whether the carcinoma had become improved or exacerbated in the course of the irradiation. He found that in case of exacerbation the signs of secondary anemia are greatly increased. In the white blood picture the leukocytosis increases in case of exacerbation, whereas in case of improvement the opposite behavior is observable. The author admits that, if the condition of the carcinoma is taken into consideration, it cannot be definitely stated how the irradiation has influenced the blood picture, but he considers the fact that the changes in the blood picture have a prognostic value of more importance than the demonstration of a ray effect. He concludes that the prognosis is generally favorable if after the irradiation the hemoglobin content and the erythrocyte values increase and the leukocyte numbers and the deviation to the left decrease. It is unfavorable if the blood status shows the opposite behavior.

### Wiener klinische Wochenschrift, Vienna

\*Enterococcal Infections of Central Nervous System. F. J. Lang, A. Lode and F. Schmuttermayer.—p. 29.

**Enterococcal Infections of Central Nervous System.**—A review of the literature on enterococci revealed to Lang and his associates that it records only three cases of enterococcal infections of the central nervous system. Therefore they feel justified in giving detailed reports of two cases, both of which ended in death. The enterococcal strains that were isolated from these two patients showed great similarity, such as in regard to the multiformity of shapes with predominantly pointed ends, in regard to the clouding of the bouillon and profuse growth already after twenty-four hours and in regard to the great resistance, the fermentative action and the reduction of dyestuffs in milk. In both patients enterococci were found in the cerebrospinal fluid that was withdrawn from the lumbar region and from the cistern. The enterococcal meningitis, which was deduced from the presence of the enterococci in the spinal fluid, was found to be the result of a cerebral abscess and of softening of the brain, which, in turn, had been caused by way of infection of the blood stream. A primary process produced

for a bilateral Babinski sign during the first week. During the first two weeks there were frequent periods of profound coma, associated with bradycardia, Cheyne-Stokes respiration and blood pressures in excess of 200 mm. Sucrose in doses of 100 cc. of 50 per cent solution was given intravenously at these critical periods. A typical response to the procedure was noted: Respirations became more regular, cyanosis was relieved, the pulse rate was increased approximately from 64 to 90, and systolic blood pressures declined from levels around 210 to readings between 150 and 160. There were occasions when deep coma and respiratory difficulty unaccompanied by hypertension and bradycardia were alleviated by the sucrose treatment. Caffeine was also employed several times.

At the end of two weeks the patient began to respond to various stimuli. Although he frequently lapsed into mild coma, he no longer suffered from recurring episodes of medullary distress. At this time he was placed on a program of intravenous sucrose (100 cc. of 50 per cent solution) every other day with spinal fluid drainage on the alternate days. On this treatment the level of consciousness gradually improved, the blood pressure became stabilized at 110/60 and the spinal fluid pressure dropped progressively from a maximum of 25 mm. to 8 mm. of mercury, a level which was reached twenty-three days after admission. During the entire course the patient's water metabolism was carefully controlled to guard against dangerous dehydration. Since his discharge from the hospital he has returned to his usual employment.

During the first phase in this case hypertonic sucrose solution proved its efficacy in relieving dangerous degrees of intracranial hypertension, as was indicated by favorable changes in those cerebral and medullary functions known from experience and experiment to be correlated with intracranial pressure. Drainage of cerebrospinal fluid probably would have been employed during the first phase had the patient not been obese and extremely difficult to manage. It was accounted an advantage that therapeutic results could be achieved without the disturbance of lumbar puncture. The steady decline of cerebrospinal fluid pressures noted during the second phase of the treatment may or may not have been due to the sucrose, which was given every other day.

#### SUMMARY

In the cases that have been presented, the efficacy of hypertonic sucrose solution administered intravenously in reducing traumatically increased intracranial pressure was demonstrated by means of the well established correlation between intracranial hypertension and compensatory arterial hypertension. In all three of these cases, compensatorily elevated systolic pressures were repeatedly lowered with concomitant improvement in the functions of the medullary centers, following administration of the agent.

It is our belief that the vasomotor, cardiomotor and respiratory functions of the brain stem constitute indicators of intracranial tension, at certain critical levels of intracranial hypertension, which probably surpass cerebrospinal fluid manometry in delicacy. Clinical signs such as depth of coma and motor activity are also indicators, and in these cases they were in agreement with the blood pressure changes reflecting improved brain function after the administration of sucrose. These are the results which would be expected from consideration of the experimental work with sucrose reported by others and cited in previous paragraphs.

The dose of sucrose most frequently employed by us was 100 cc. of 50 per cent solution, corresponding to from 0.25 to 1 Gm. of the sugar per kilogram of body weight. Occasionally we gave as much as 2 Gm. per kilogram. In the cited experimental work, doses from 3 to 6 Gm. per kilogram of body weight were

employed. We contented ourselves with the smaller doses because we could see definite therapeutic results from them and because we conceived that a violent osmotic effect on the brain might be injurious, just as the abrupt and extreme reduction of pressure by lumbar drainage of cerebrospinal fluid is known to be dangerous.

In no instance did we observe any untoward effects that could be attributed to sucrose, although in our opinion disadvantageous and even dangerous tissue dehydration might have occurred had the patients' water metabolism not been given careful attention. Profuse diuresis always occurred after the administration of sucrose, and the specific gravity of the urine was always high, owing to the direct excretion of the sugar. For this reason concentration-volume data, which would ordinarily indicate satisfactory renal elimination of nitrogenous products, could not be relied on and recourse was made to determination of blood nitrogen in several instances.

When due consideration is given to questions of nitrogen elimination and water metabolism and to indications for operative intervention, we believe that osmotic therapy is a valuable adjunct in the management of some cases of brain injury and that sucrose is as effective as dextrose in producing therapeutic changes when intracranial pressure is elevated to a critical level. If further experience confirms this impression, sucrose should be adopted as the agent of choice for influencing the brain osmotically because of its freedom from the objectionable (but not prohibitive) feature of producing a secondary rise of intracranial pressure, experimentally proved with respect to dextrose.

#### CONCLUSIONS

1. Literature and our personal experience indicate the usefulness of intravenous treatment with hypertonic dextrose solution as an adjunct in the management of cases of acute brain injury.

2. Literature establishes that the intravenous injection of a single dose of 50 per cent dextrose solution leads to an eventual rise of cerebrospinal fluid pressure beyond the initial pressure. This action of dextrose is interpreted as a disadvantage even though clinical experience shows that repeated, correctly timed doses of the substance obviate serious consequences.

3. Literature establishes that sucrose in 50 per cent solution can be administered intravenously in experimental animals and in human beings with intact brains without producing a secondary rise and with an effective, protracted depression of cerebrospinal fluid pressure.

4. Clinical experience with twenty-five cases of acute brain injury tends to show that 50 per cent sucrose solution injected intravenously is without untoward effects and effectively replaces dextrose for osmotic therapy.

5. In three cases that are presented in summary, clinical signs and blood pressure responses established with considerable certainty that the intravenous injection of 50 per cent sucrose solution led to effective reductions of intracranial pressure.

6. In view of all the facts cited and of our own experience, it is concluded that there is considerable advantage in the substitution of sucrose for dextrose in the osmotic therapy of increased intracranial pressure occurring in cases of acute brain injury.

## LEADERSHIP IN MEDICAL EDUCATION

RAY LYMAN WILBUR, M.D.

Chairman of the Council on Medical Education and Hospitals of the  
American Medical Association

STANFORD UNIVERSITY, CALIF.

Medical education slipped during the depression and has not yet regained its full stride. The recent nationwide survey of the medical schools made by the Council on Medical Education and Hospitals of the American Medical Association has compelled it to remove some medical schools from its approved list and to give warnings or suggestions to others so that improvements can be made. The main functions of the Council are to hold the level of medical education as high as is reasonable, to detect and report weaknesses that may occur, and to bring out the changes taking place in medical knowledge that require a shift in the emphasis on the various subjects making up the medical curriculum.

Primarily the cause of the decline in the efficiency of our medical schools is due to lack of adequate financial resources. More endowments and annual appropriations are needed by practically all the medical schools in the country in order to ensure the carrying on of medical education on a university basis.

Bringing medical education up to university standards has been the great achievement in American medical education of the last quarter of a century.

Private hospitals and university hospitals associated directly with medical schools have had unusual problems to meet because of increased costs, decreased occupancy and lower rates. This has been combined with a growing competition of hospital beds supported in one way or another by taxation. The evidence in our hands at present indicates that there will continue to be further absorption of the hospital field by various units of government. For the general welfare it is most important that the private hospitals, particularly those used by medical schools for the instruction of students, should be strengthened in every way that is possible.

### MEDICAL STUDENTS

There has been a marked increase in the number of students applying for admission to our medical schools. The temptation to take more students than could be well handled was a natural one under the financial pressures to which our schools have been subjected. A reduction in the quota of students received for admission is now being made by a number of our medical schools. When the entering classes are brought into line with the existing facilities there is good reason to believe that a sufficient number of well trained physicians will be graduated to care for the medical needs

of the nation. The range of the ordinary physician has been vastly increased by assistants, nurses, hospitals, automobiles, good highways and telephones.

Most of the students entering our medical schools are well selected and have a good preliminary training. The attempt to evaluate their personal qualities, aside from their records on paper, is beginning to show encouraging results. This is the most difficult part in making selections, for the value of the physician to his patient and to his community depends so much on his own personal qualifications aside from the medical training itself.

Medical students are still deficient in adequate training in those subjects that have to do with our social and economic structure. The specific requirements are held at such a level that only the exceptional student gets that training in language, history, psychology, economics, biology, chemistry and physics that is desirable. The junior college period is too short for an adequate preparation for the medical course. A longer preparation with a required and supervised intern year is needed to ensure a medical profession that knows its job and can keep up to date with all its responsibilities.

### MEDICAL CURRICULUM

Our medical schools still for the most part endeavor to impart too large a body of information to the medical student. There is an aim to be inclusive, rather than selective, in presenting the vast knowledge of the medical world. It is hard for us to realize that we must teach the student to swim in a steadily changing current and that there is no possibility of teaching him all of medicine. Throughout his life he must accommodate himself to new facts as they are brought forward by medical research.

The sense of proprietorship that various well placed departments have in regard to the time of the student has made it difficult in many institutions to bring in adequate training in the prevention of disease, public health, psychiatry, physical therapy, and the social and economic phases of medical practice which have now become dominant in various medical fields.

There is a specific need to coordinate and unify the instruction of the medical student so that such a disease as syphilis, for instance, may be studied in all its aspects rather than handled by a single clinic. It may simplify the treatment of syphilis to have it given in one place, but its diagnosis is a part of every department in the medical school.

### GRADUAL MEDICAL INSTRUCTION

The United States is far behind its possibilities in the instruction of medical graduates. There has been some improvement in certain of our large cities; and the increase in emphasis of the special boards on adequate training is having its influence on our hospitals as well as on the training of specialists.

On admission he had been unconscious for eighteen hours. The respiration was typically Kussmaul and the pulse rate was 120. The blood pressure could not be obtained because he was nearly pulseless. The skin was cold and dripping wet. The urine showed a red test for sugar and no diacetic acid. Although he had received 150 units of insulin before admission, the blood sugar was 0.35 per cent and the plasma carbon dioxide combining power was 17 volumes per cent. The nonprotein nitrogen of the blood was 80 mg. He was given 800 units of insulin during the next seven hours, but during this time the blood sugar steadily rose to 640 and finally to 780 mg. with the carbon dioxide still at 17 volumes per cent. The nonprotein nitrogen rose before death to 93 mg. per hundred cubic centimeters. At autopsy, March 30, the main changes were acute pancreatitis with many areas of fat necrosis. The main pancreatic duct was filled with pus. The liver, weighing 2,400 Gm., showed liver cells infiltrated with fat droplets, but scattered nuclei were distended with glycogen.

CASE 4.—A factory worker, 40 years of age at the onset of diabetes in July 1918, had been under careful treatment since 1920. He began the use of insulin in 1923 and had continued it faithfully since, although he had not constantly been on a careful dietary regimen. He was known to have had angina pectoris, for which treatment had been given in February 1936. February 8 the blood sugar was 0.28 per cent. He entered the Framingham Union Hospital March 6 in the service of Dr.

TABLE 2.—*Lipemia in Diabetic Coma with Pancreatitis (Case 2)*

Date, 1931	Plasma

April 10, 11 p. m. ....	1,162	7,536	6,291
April 11, 2 a. m. ....	1,084	7,000	6,480
April 11, 4 a. m. ....	1,020	8,032	6,922

Roy Morse, through whose courtesy I saw the patient and am able to report the case. The history preceding the onset of coma was vague. Recently he had omitted insulin. Four days previously a tooth had been extracted without anesthesia and he had seemed drowsy ever since that time. On the night before admission he asked for water, suddenly became stiff and appeared to stop breathing. From this time on he was semiconscious.

The blood sugar was 640 mg. per hundred cubic centimeters and the carbon dioxide combining power was 15 volumes per cent. The nonprotein nitrogen was 75 mg. per hundred cubic centimeters. During the first three hours in the hospital he received 170 units of insulin. Gastric lavage gave a large amount of dark brown fluid. A total of 6,000 cc. of salt solution was given during the first ten hours of his stay in the hospital. By that time the blood sugar had fallen to 0.12 per cent. During the night he began to sweat and received 500 cc. of 5 per cent dextrose solution. The next morning he seemed rather bright and in good condition at 10 o'clock; however, the pulse was irregular and some extrasystoles were present. It was thought at this time that coronary occlusion was a possible complication. He died suddenly later that same day. At autopsy the chief pathologic changes were in the pancreas. The entire length of the pancreas was found to contain scattered areas of firm, greenish white tissue, most marked about the head. The pancreatic tissue was reddened and firm and weighed 150 Gm. Scattered over the surface in the upper left quadrant of the abdomen the omentum showed a number of small white rounded fecal areas rather soft in consistency, which gave the appearance of fat necrosis. When the omentum was drawn up the transverse colon and its surface showed also minute white areas of fat necrosis. The liver weighed 1,800 Gm. and showed lipid infiltration.

#### INCIDENCE OF PANCREATITIS

Fitz<sup>1</sup> divided acute pancreatitis into three types in 1889, hemorrhagic, gangrenous and suppurative. Of these three types the suppurative type may be subacute or chronic, although it may also be acute. Acute pancreatitis is rare.

Rienhoff and Lewis<sup>2</sup> analyzed all the cases of pancreatic disease (excluding diabetes) admitted to Johns Hopkins Hospital from 1889 to 1932. Only 15 cases occurred in the surgical service of 78,000 patients. In this group only eighteen cases of acute pancreatitis were found, including two cases of pancreatic abscess. It was diagnosed only seventeen times in seven years at the Mayo Clinic, according to Walters, Puestow and McCaughan.<sup>3</sup> These seventeen cases were not all of the hyperacute stage but included varying degrees of acute and subacute inflammation. Apparently acute pancreatitis is on the increase, however. Hamperl<sup>4</sup> reports sixty-seven cases of acute necrosis of the pancreas among 20,000 autopsies, or one in 300. This is about double the rate in a similar series of autopsies in an earlier period and must have included cases in which there were only small areas of necrosis. Among 21 autopsies on diabetic patients at the Deaconess Hospital, acute pancreatitis was found only in the five cases of coma.

Acute pancreatitis has been extremely rare in diabetes, so far as the clinical diagnosis is concerned. Among 2,052 operations on diabetic patients at the New England Deaconess Hospital in thirteen years, of which 213 were abdominal, primary acute pancreatitis has never been diagnosed preoperatively and has been found only rarely as a complication of acute gallbladder disease. One operation was performed for a pancreatic cyst. In another case chronic pancreatitis had been diagnosed by x-ray examination by means of the numerous calcified areas throughout the pancreatic tissue. In comparison with general autopsy or clinical series, therefore, the frequency of acute pancreatitis in diabetic coma appears extraordinary.

#### GENERAL SYMPTOMS OF ACUTE PANCREATITIS

The symptoms are variable, but the main symptoms are pain, obstipation, collapse and vomiting. The pain is usually epigastric and severe and an important point is that the pain and tenderness to palpation extend to the left as well as the right of the midline. The tenderness corresponds with the actual anatomic outline of the pancreas. Often the onset is with a dull pain, which rapidly increases to maximum severity in a few hours. Sometimes the pain is dull or crampy. The pain simulates gallbladder disease in some instances. Frequently the patients give a history of intermittent abdominal distress or discomfort over a considerable period preceding the present illness. Vomiting is a most important symptom. Persistent vomiting over a period of days, suggesting intestinal obstruction, should lead to the diagnosis of pancreatitis, especially when the vomitus is not fecal in nature. Cyanosis and profound shock are outstanding features in severe cases. The white count is usually elevated. Jaundice occurred in eight of the seventeen cases at the Mayo Clinic, and in 44.4 per cent of the cases at Johns Hopkins Hospital as described by Rienhoff and Lewis.<sup>2</sup> Two patients with jaundice in the Mayo Clinic series gave no evidence whatever of cholecystitis or cholelithiasis even at operation. Diarrhea, often mentioned as a symptom of pancreatitis, was not present in any of their cases. At operation the pancreatitis was found to be the primary cause in ten of the seventeen cases. In the other seven pancreatitis was present, but it was of less importance.

assured that the candidates have been exposed to sound training. There is no other agency capable of supplying the boards with reliable and disinterested information of this character.

It has been said that the medical schools should be allowed to regulate their own affairs and appraise their own efforts; that a professional body should not intervene in matters pertaining to education; that, in any case, a policeman is no longer needed. In the United States, at least, the history of medicine, law and dentistry demonstrates incontrovertibly that professional schools, with their proprietary and commercial background, cannot lift themselves by their own bootstraps. The weaker schools always oppose any raising of standards; and the stronger schools, even though themselves not directly affected, too often lend their influence to protect institutions and practices which they ought fearlessly to condemn. "Senatorial courtesy" and "group solidarity" prevail over sound and unbiased judgment as to the interest of the public and the profession.

From a purely practical standpoint, no other body than the American Medical Association has the means with which to carry out an effective appraisal of medical schools. In connection with the current survey, the Association will have spent between forty and fifty thousand dollars. Is the College Association, the Federation of State Medical Boards or any other group except one of the foundations in a position to do as much? And yet we feel that our study was not as thorough as it should have been. More important is the fact that only the American Medical Association can approach the problem uninfluenced by political pressure or local self interest. Would any one have more confidence in a grading of medical schools conducted by themselves? Or what chance would there be of freedom from political intervention if the approval of schools rested with the state boards?

The record of thirty years shows that the Council on Medical Education, exercising an effective and impartial supervision over the training of physicians, has brought about an advance unparalleled in the history of education. It alone can furnish the state boards a trustworthy list of schools from which graduates should be admitted to the licensing examination, which, in the absence of a comprehensive practical examination, is the only safeguard against ignorance and incompetence in medical practice.

In the efforts of the Council to study the medical schools and the hospitals and thereby protect the public welfare, we have had the assistance of the Association of American Medical Colleges and that of the Federation of State Medical Boards of the United States. As has just been shown, it was inevitable that the primary responsibility of the survey should fall on the Council. All three organizations have a common purpose, however: the improvement of medical education and the protection of the public. At times the Council has sought and received considerable cooperation from the representatives of both these boards, but of late there has been a tendency in some quarters to criticize the Council and to oppose its policies. This is probably inevitable, under the pressures that exist. We hope, though, that there will come about a better understanding of the common purposes which these organizations have in mind and that we can get a degree of cooperation that will permit a uniform and united front in dealing with the inadequacies of some of our medical

schools and hospitals and in raising our standards to keep in harmony with the steady and persistent advances in medical knowledge. Some one organization has to take the lead and the responsibility in difficult and somewhat disagreeable tasks of this kind. That the Council has done for many years, and that it proposes to do in the future. By all working together toward a common end we should be able to improve medical education, hospital care and postgraduate medical instruction in the United States and thereby do more than could be done in any other way to improve the private and public health of the future.

## CLINICAL EXPERIENCE IN THE USE OF SUCROSE INSTEAD OF DEXTROSE

IN THE OSMOTIC THERAPY OF INCREASED INTRACRANIAL PRESSURE OCCURRING IN CASES OF  
ACUTE BRAIN INJURY

E. VERNON HAHN, M.D.

FRANK B. RAMSEY, M.D.

AND

KENNETH G. KOHLSTAEDT, M.D.

INDIANAPOLIS

Since 1922, concentrated dextrose solution injected intravenously has been widely recommended and used in the management of cases of acute brain injury for the purpose of reducing excessive intracranial pressure.<sup>1</sup> Almost from the inauguration of this osmotic therapy, various critics advanced suspicions and ostensible proofs that it does not regularly reduce intracranial pressure and that, when it does, the reduction is followed by a reactive elevation.<sup>2</sup>

Notwithstanding these criticisms of intravenous, concentrated dextrose therapy, the method has continued in use. Sachs,<sup>3</sup> one of the earliest sponsors of osmotic treatment of increased intracranial pressure, pointed

The cooperation of Eli Lilly & Co., which provided 50 per cent sucrose in ampules for the cases treated in the Indianapolis City Hospital, is gratefully acknowledged.

Abnormalities in the lipid content of the blood, liver and spleen represent a fascinating problem alike to pathologist, physiologist and clinician. The large liver with fat-filled cells often associated with lipoid histiocytosis in the spleen is familiar to the pathologist in cases of advanced diabetes, either with acidosis or with great emaciation and often occurring with lipemia. Warren and Root<sup>7</sup> reported three cases studied with various stains to determine the type of fat deposited. Two of these patients died in coma. All three showed fatty deposits in the liver cells and reticulo-endothelial cells lining the sinusoids. Fatty invasion of the liver cells is seen in acute toxic conditions, such as phosphorus or chloroform poisoning, and in a variety of metabolic disturbances, such as pernicious anemia, the Schüller-Christian or the Niemann-Pick syndrome, and obesity. Also in certain stages of glomerulonephritis an increase in the cholesterol of the blood, often with fatty degeneration in the kidney, occurs. To the physiologist the variation in fat content of the liver, produced almost at will in the depancreatized animal by varying the carbohydrate and fat proportions of the diet and the amount of insulin given, represents perhaps the best known method of demonstrating the influence of a hormone on fat deposition. Best<sup>8</sup> has shown that the deposition of fat in the liver in the depancreatized dog can be controlled by the addition of choline in the diet. The influence of the pituitary gland on the fat content of the liver, studied by many physiologists, may be reviewed in the work of Raab<sup>9</sup> and of Houssay.<sup>10</sup> Only recently Dragstedt<sup>11</sup> has isolated a hormone ("lipocaic") from the pancreas with which he is able to influence the amount of fat deposited in the liver cells.

To the clinician accustomed to thinking of lipemia in association with the most severe types of diabetes, the concurrence of acute pancreatitis with severe diabetes would be expected to result in severe lipemia with fat deposition in the liver and spleen. The fact that lipemia occurs in only a limited proportion of cases of coma suggests that in these some special added factor is present. Possibly lipemia is due in such cases to acute pancreatitis. Brunner<sup>11</sup> described lipemia occurring in acute pancreatitis without diabetes, Joël<sup>12</sup> found lipemia in chronic pancreatitis and also in a case of acute pancreatitis without carbohydrate disturbance. Brunner<sup>11</sup> reports four cases of acute pancreatitis without autopsy or surgical verification. The diagnosis rested on the symptoms, physical signs and increased diastase in the blood and urine. In the first of the four cases, a man, aged 35, the total cholesterol of the plasma was 1,040 mg.; free 540 and ester 500. The urine contained 3.2 per cent of sugar, and the blood sugar was 0.218 per cent in one analysis. However, after recovery from the acute attack no evidence of the diabetes could be found, even with dextrose tolerance tests, and he regarded his patient as nondiabetic. In the other three patients plasma cholesterol values were 264 mg. in one and normal in the other two. The first patient was treated with insulin, and a fall in the lipemia occurred. In ten days hypoglycemia attacks were observed. There was no evidence of abnormal fat breakdown, as shown

by acetone tests. It seems possible that the lipemia was not a simple transport lipemia but that the pancreas was directly involved in fat metabolism and so was responsible for the lipemia.

#### CONCLUSIONS

1. Acute pancreatitis, unsuspected during life, was found as a cause of death in four cases out of twenty-six in which death occurred during or after recovery from diabetic coma.

2. Causes of death in diabetic coma cannot be ascertained and statements regarding the efficiency of treatment should not be made without the knowledge afforded by postmortem examinations.

3. Acute pancreatitis must be searched for in every case of severe diabetic coma, and the differential diagnosis should include acute hepatitis, perforated ulcer and acute cholecystitis, as well as the other causes of acute upper abdominal symptoms.

4. Lipemia occurred in the only one of the four patients on whom blood analyses were made. Lipoid infiltration of the liver with enlargement of the latter occurred in all four cases.

### CLINICAL PROBLEMS IN SYPHILIS CONTROL TODAY

JOHN H. STOKES, M.D.

PHILADELPHIA

Gentlemen, the surgeon general and his aides have invited me to perform a high pressure miracle by compressing a syphilis text into thirty minutes of manuscript. I must therefore warn you that alternations of heat and frost are inevitable in such an experiment, that pressure will be enormous, and that any one who leaves the caisson during the presentation will be seized not with the "bends" but with the "whoopies." As the performer of the experiment, allow me to hope that the product will read hot, and the experiment not end in frost.

#### PROBLEM I. THE CHIEF AND HIS CLINIC

The League of Nations investigation brought to the dignity of statistical demonstration the fact that clinics, widely regarded as the chief instruments for the control of syphilis, are so inefficiently run the world over that 20 per cent of their early syphilis material has not received even the minimum of darkfield examination and serologic testing required by the past two decades' knowledge of the disease. It was apparent, moreover, though our faces were saved by an absence of figures, that chiefs do not know what systems their clinics are following, are not able to describe what is actually going on, and believe methods to be in use and procedure in process of study which are not. The moral is obvious, nor can we flatter ourselves that our own country or our most select organizations are exceptions. Know your machines; appear at unexpected times and places, call periodically onto linoleum if not carpet even the most trusted members of your staffs; maintain disagreeable (or what one of my associates once called "bristling") conferences. Insist on annual comparative reports, maintain an arsenical injection register, treatment records that show on a single sheet and at one glance all a patient is receiving and as much of what it is doing to him serologically and symptomatically as

In the literature just cited, as well as in other contributions on dealing with sucrose, it is pointed out that this disaccharide, when injected intravenously, is not hydrolyzed in the blood stream or tissues. It therefore does not add to the available dextrose of the body and is totally without nutritional value. This fact has obvious bearing on the choice between dextrose and sucrose in the treatment of certain cases of brain injury when the nutritional factor is important.

If the effect of hypertonic sucrose solution observed experimentally, as cited in the foregoing account, can be duplicated clinically in cases of brain injury, it is obvious that sucrose offers advantages over dextrose in the treatment of this condition. Indeed, we suspect that many others than ourselves have made this substitution. Nevertheless, we have seen no report of the use of sucrose in brain injury cases, except for brief references by Davis,<sup>7</sup> and by Glass,<sup>14</sup> and feel that our experiences with it will be of interest.

OSMOTIC THERAPY WITH FIFTY PER CENT  
SUCROSE SOLUTION IN CASES OF  
ACUTE BRAIN INJURY

Our combined clinical experience with the administration of 50 per cent sucrose intravenously in cases of brain injury comprises twenty-five cases in which one or more doses of the agent were given. Much of this material does not lend itself to an analysis of the effect of the treatment. Mortality statistics, particularly, would be of no value because of the differing severity of the cases, some of which were so grave that no therapy could be expected to succeed. However, it is pertinent to note that in none of this experience have we seen any untoward results which could reasonably be attributed to the use of sucrose.

For a demonstration of the results which we believe can usually be expected, under certain pathologic conditions, from the intravenous injection of 50 per cent sucrose, we have selected the following three cases, presented in summary together with interpretative comment:

CASE 1.—R. H., a boy, aged, 12 years, sustained a compound fracture a little to the left of the vertex, with depression of fragments. Coma was continuous from the time of the accident for four days and was followed by extremely limited responsiveness for the next two weeks. After this the condition gradually improved and we are advised that he is now substantially normal.

Immediately on admission the compound fracture was treated surgically without anesthesia. Depressed bone was partly removed and partly elevated. The dura was intact and was not opened, in view of the contamination of the wound.

In addition to profound coma, the patient displayed spontaneous convulsive movements involving all the extremities, often with the head and body turning. Babinski's sign was present on both sides and hyperreflexia was general. Periods of Cheyne-Stokes respiration occurred. The blood pressure varied from 110 to 172 systolic, the higher pressures corresponding with pulse rates from 60 to 70.

For the first four days the patient was given 50 per cent sucrose in 50 cc. doses approximately every three hours. The urinary output was watched and kept above 600 cc. for each twenty-four hours by hypodermoclyses until swallowing became effective.

Lumbar puncture was not done in this case, and we have no manometric data as to the effect of the sucrose on intracranial pressure. Clinically, however, it was invariably noted by the intern, by the special nurses and by ourselves that improvement followed each hypertonic treatment. Cheyne-Stokes respiration would frequently give way to normal rhythm within ten minutes after a dose of sucrose. Slight cyanosis and convul-

sive phenomena were likewise abated. On one occasion a blood pressure of 172 systolic, 78 diastolic prior to sucrose fell to 142/88 coincident with improvement of color and respiration. The same sequence was noted a number of times in smaller degree.

It is possible to argue that this extremely severe injury might have been survived without specific treatment. On the other hand, the patient's condition appeared to be critical many times during the first four days, and each time a favorable response to sucrose was obtained. Caffeine, which the special nurse had been ordered to give as a last resort, was never needed.

CASE 2.—C. L., an obese, plethoric man, aged 68, with a history of excessive wine drinking, fell, striking his head in the right occipital region on a concrete floor. After about ten minutes of unconsciousness he was able to walk with assistance. Three hours later he vomited, became semicomatose and was brought to the hospital. Neurologic signs and the general course suggested compression of the right hemisphere. A hematoma was present at the site of the trauma, but a roentgenogram showed no fracture. Lumbar puncture proved to be impossible because of a large hematoma, which added to the excessive thickness of the back. On account of the patient's precarious condition, operation for intracranial hemorrhage could not be carried out until two weeks after his admission, when lumbar puncture showed xanthochromic fluid under a pressure of 30 mm. of mercury. Perforation of the skull in the right parieto-occipital region revealed a subdural hematoma of about 50 cc. Contralateral exploration was not done, since the brain was flaccid after the evacuation of the hematoma and since the patient was still in a most serious condition. Following operation, the patient improved. Lumbar punctures on the third and fourth days showed clear fluid under a pressure of 12 mm. of mercury. The second week after operation, he developed jaundice, hiccup, difficult swallowing and pneumonia, and he died one month after admission. Autopsy was refused.

Treatment during the first two weeks consisted of elevation of the back rest, sedation with codeine when necessary, limitation of fluids to 750 cc. for each twenty-four hours, and 50 per cent sucrose solution intravenously as often as every five hours in doses of 100 cc. when deep coma and Cheyne-Stokes respirations indicated dangerous cerebral and medullary distress.

During the first three days sucrose was given nine times. A record of the blood pressures during this period shows that in no instance was the systolic level raised significantly following the treatment. On the contrary, drops of from 10 to 40 mm. were observed in from one to three hours after the injections in five instances. Each of these periods of lowered systolic pressure corresponded with clinical improvement as indicated by decreased cyanosis, more normal respiratory rhythm, better pulse and rallying consciousness. Fortunately the patient's physician took his blood pressure immediately after the fall, finding it 148/80. On admission it was 174/108. Except for the periodic drops mentioned, it hung about this hypertensive level until after the evacuation of the hematoma, when it became fairly stable at 130/80, persisting at that level until the last few days of the illness.

It appears unlikely that this patient would have survived many of his periods of medullary crisis if nothing had been done to relieve his vital centers of excessive pressure as manifested by the well known compensatory rise of blood pressure as well as by trustworthy clinical signs. During the first two weeks, lumbar puncture was not possible and osmotic therapy was the only alternative to operative treatment, which we feared to employ at that time. Sucrose apparently answered the purpose of osmotic treatment satisfactorily, enabling us to tide the patient over to a time when trephination could be done without precipitating a fatality.

CASE 3.—D. Z., a man, aged 57, sustained a basal skull fracture in an automobile accident and was brought immediately to the hospital in a state of coma, which persisted for three weeks. Neurologic examination was negative at all times except

14. Glass, R. L.: Head Injuries, *J. Indiana M. A.* 29: 568 (Nov.) 1936.

the fourth injection leads to 64 per cent relapse; treatment prolonged to from five to nine injections leads to only 14 per cent relapse. The Cooperative Clinical Group dividing line of 20-20 between much and little is a good one on which to set up one's first target, for twenty injections each of arsenical and heavy metal, or more, have so consistently shown themselves to be superior at all points to anything less that they may well serve as the ring just outside the bullseye of individual cure, for one's shooting efforts.

It is now reasonably established that neoarsphenamine is an adequate drug, even in comparison with its solitary superior, arsphenamine. It should be recognized that its adequacy depends to an unknown degree on the prolonged use with it of a heavy metal, and particularly bismuth, in a continuous system. One should think of neoarsphenamine then only in terms of what I call the standard or 30-60-03 system—thirty injections of the arsenical, sixty of bismuth subsalicylate, no rest intervals during the arsenical phase, three years' minimum of treatment-observation. In terms of courses this is five arsenical, ten bismuth, in sixty-five weeks. Again, one who has been interested for years in testing new drugs takes the liberty of urging physicians as part of public health control not to depart from the established drugs and methods at the lure of each new "discovery," each new sales campaign, or even any single authoritative appraisal. The business of the physician just now is with the established, not the experimental, and experimental a new arsenical remains for five years after its birth, even so far as mere infection control values are concerned. Its ultimate evaluation takes a decade and more at the least.

There is now satisfactory evidence for the belief that arsenical dosage must be larger rather than smaller than it has been in the past. The differences traditional between men and women can be ironed out. The average therapeutic dose of neoarsphenamine should be 0.3 Gm. for the first and from 0.6 to 0.75 Gm. for subsequent injections of a course. Before the dose is set, look at the patient: is it shrimp or a sea-going 500 pound lawyer? Give to each his full desert, by weight.

Thanks to the material of the Cooperative Clinical Group, one can, turning now to the heavy metal factor, define several points of interest. Bismuth has apparently established its worth over mercury, especially in the prevention of relapse; nearly three times as frequent under arsenical-mercury as under arsenical-bismuth therapy in early syphilis. Speaking from personal impression, the use of bismuth does seem to prolong or even stir up seropositiveness, but this is no necessary disadvantage, though the serologic results of a bismuth therapy can often be better judged at the beginning of the next than the end of the present course, so to speak. The heavy metal is apparently the chief aggregate reactivity provoker in treatment, but as between continuous and intermittent use, excluding the arsenical from consideration, there seems to be little difference. With bismuth at least it is possible to give astonishingly long courses of standard preparations without a sign of difficulty, provided the dose is not excessive and the mouth is watched and protected. With bismuth the need for the routine weekly urine examination passes, a great relief to the conscientious clinician.

The serologic and spinal fluid tests in early syphilis deserve several emphatic words. A drug-testing organization should run a weekly test on all patients, but others can reduce the strain on their laboratories by testing only by the course. In the present state of

public understanding of serologic procedures, it is essential to make it clear to the patient at the start that his blood test means nothing with reference to his treatment schedule. One large public, the British, is actually withheld, by recommendation at least, from any knowledge of its serologic progress through the use of code in records, lest it adopt the "fiscal last mark" of Colonel Harrison and vanish with the first or second negative. The performance of multiple tests on treatment patients is not essential as a routine, but it is essential to take seriously weak positives, when they do occur in treated early syphilis, as forewarnings of a relapsing tendency. It is wise, too, to repeat the test on seronegative primary syphilis the week after the first arsphenamine and, if it is then even partially positive, to rate the case as a seropositive primary rather than a seronegative, from the standpoint of total amount of treatment required. A return to a strongly positive blood after a series of negatives in either early or latent syphilis is a serious warning. One should at once examine the spinal fluid and incidentally inspect the skin, feel for the liver and spleen and look at the iris and sclera. The most recent Cooperative Clinical Group studies, under O'Leary, establish this warning of asymptomatic neurosyphilis beyond doubt.

The fixed positive serologic test, emerging from the smoke of a syphilologic battle, especially early in the disease, is apparently one of the most discouraging dénouements the patient and his doctor have to face. It is more than anything else the penalty of irregularity and noncontinuity in treatment, and it would almost seem worth while to tell the patient so at the start, if boggy-man tactics ever do any good. Once the event is established (and it takes a year of effective treatment to prove it), the following lights define the course: Examine the spinal fluid—if negative, draw two full breaths; one for the patient, one for yourself. Then give ten more neoarsphenamine injections if tolerance has been good, and another year of ten-injection bismuth courses with eight week rest intervals. Next stop for a year, or give potassium iodide 20 grains (1.3 Gm.) three times a day, two months on and two off during that time. Don't take tests oftener than once in three months; don't chase a positive through a series of laboratories, multiple test methods and a forest of one, two and three pluses. Unless marriage or child-bearing is imminent, be content to wait awhile at the end of the extra year of treatment. If still positive after that, don't buy or patronize a fever therapy machine or enthusiast; try a little boiled milk intramuscularly first and then some more bismuth. Take the blood serologic test three months after the last bismuth. Panic over irreversible positives in spinal fluid-negative patients is, it seems to me, often needless and rarely calls for anything extreme. A living dog is better than a dead lion, and a wisely indifferent, reassured patient better than a phobic nervous wreck.

The principles governing the examination of the spinal fluid, now a proved necessity in the management of early syphilis, seem to me to be these: The test should not be done until rapport with the patient is fully established. It need not be done before the sixth month of a routine continuous schedule in early syphilis. It should not be deferred beyond the fiftieth to the period, which usually means about the fiftieth to the fifty-fifth week. A fluid normal except for a slight rise in cell count, e. g., above 4, I believe demands a repetition of the test within the ensuing year. On the other hand, an absolutely uneventful serologic reaction

# DIABETIC COMA AND ACUTE PANCREATITIS WITH FATTY LIVERS

HOWARD F. ROOT, M.D.

BOSTON

The occurrence of acute pancreatitis in cases of diabetic coma explains occasional deaths that would seem to be examples of failure in the treatment of the acidosis. In my experience, among twenty-six patients who died during or following diabetic coma, the post-mortem examination revealed acute pancreatitis in four instances, in none of which the diagnosis had been suspected during life. In table 1 only ten of the twenty-six fatal cases of coma represented uncomplicated paths. These were due to tardy diagnosis and delay in treatment before admission to the hospital. Septicemia and infections, such as pneumonia and renal abscesses, account for nine deaths. In three cases the causes were respectively coronary occlusion, pulmonary embolus, and hemorrhage for a duodenal ulcer. The remaining four cases of acute pancreatitis represent an incidence of nearly 15 per cent. So high a frequency clearly indicates that the diagnosis of acute pancreatitis must always be considered in any case of diabetic coma in which the condition of the patient is extreme and in which prompt recovery does not ensue. Therefore it has seemed worth while to report these four cases of acute pancreatitis in diabetic coma which were proved at autopsy, with details of their clinical history.

## REPORT OF CASES

CASE 1.—An American housewife was 40 years of age at the onset of diabetes in September 1922. Aug. 8, 1923, the urine contained 6.6 per cent of sugar, the blood sugar was 0.27 per cent, and she weighed 147 pounds (66.7 Kg.). At this time she was treated in the hospital with good results and discharged, taking 15 units of insulin in two doses, 8 units in the morning and 7 at night.

She reentered the Deaconess Hospital Sept. 25, 1925, with the history that during the past five months she had been breaking her diet and losing strength. Two days before admission she was given a cathartic and hot whisky and had pain in the abdomen. When first seen by her local physician she was thought to be in an insulin reaction and was given the juice of an orange with sugar. Her breathing became labored. On the day before admission, nausea and repeated vomiting occurred; the food was undigested and not bloody. She had received 225 units of insulin. She was finally sent to the hospital because of failure to improve. On admission she had typical Kussmaul respiration, the eyeballs were slightly soft, the tongue was brown and dry, there was a slight acetone odor to the breath, the pulse rate was 108 and the blood pressure was 110 systolic, 80 diastolic. No abdominal tenderness or masses were made out. The report of the chemistry of the blood and urine was important. The specimen of urine showed 0.3 per cent of sugar with only a faint trace of diacetic acid, and an examination of the plasma for acetone (qualitative test) showed a moderate amount. The white blood count was 24,500, the blood sugar was 0.44 per cent, the plasma carbon dioxide combining power was 8 volumes per cent and the non-protein nitrogen of the blood was 98 mg. Red blood cells numbered 4,616,000 and plasma chloride was 607 mg. per hundred cubic centimeters. Between 5 o'clock in the afternoon, when she was admitted, and 7 o'clock the next morning she received 160 units of insulin; the blood sugar had fallen at that time to 0.25 per cent and the carbon dioxide combining power of the blood done on five occasions had risen to 14 volumes per cent. During the next twelve hours she was entirely unresponsive; breathing continued to be labored and gradually became much more feeble and shallow. Râles developed in both bases and over the front of the chest. The liver edge was palpable three fingerbreadths below the costal margin. The abdomen became distended at the time of her death, 7:15

p. m., September 27, when the nonprotein nitrogen was 81 mg. per hundred cubic centimeters and the blood sugar was 0.23 per cent. The autopsy report may be summarized as follows: Numerous areas of fat necrosis were found on the serous surface of the transverse colon medial to the hepatic flexure and on the peritoneum overlying the pancreas. A large firm liver, weighing 2,280 Gm., showed extensive fatty metamorphosis throughout. A gallbladder was filled with small stones with delicate adhesions to the surrounding structure. The heart weighed 310 Gm.; the coronary arteries were hard and tortuous owing to calcified atheromas. Calcified atheromas were present in the aorta. The spleen weighed 185 Gm. and the pancreas weighed 85 Gm. The latter was normal in appearance externally, with the exception of numerous small yellow elevations over its surface. A grayish yellow thick fluid was expressed from the pancreatic duct. Branching areas of necrosis extended throughout the gland, apparently following the course of the pancreatic duct and its branches. The kidneys were large and soft, with a glistening capsule, granular surface and microscopic evidence of chronic vascular nephritis.

CASE 2.—A factory worker was 17 years of age at the onset of diabetes in June 1930. He entered the hospital April 10, 1931, with a history of diabetes in two other members of the family and a record from his physician stating that he had consistently refused to take insulin and follow treatment during the six months preceding his admission. Two days prior to his admission he complained of pain across the upper part

TABLE 1.—Causes of Death in Twenty-Six Cases of Diabetic Coma Occurring from Two to Thirty-Two Days After Admission, with Autopsy

	Cases
Acute pancreatitis .....	4
Septicemia following local infections (appendix, foot, labium, mastoid, prostate, neck).....	6
Other causes (1 case each with coronary occlusion, lobar pneumonia, pulmonary embolus, embolic lung abscess, renal abscesses, hemorrhage from duodenal ulcer).....	6
Coma uncomplicated .....	10

Twenty-five cases from the George F. Baker Clinic, N. E. Deaconess Hospital, Boston	
One case from the Framingham Union Hospital, Framingham, Mass.	

of the abdomen with nausea, but he did not vomit. He was excessively thirsty and complained of labored breathing and cramplike pains in the upper part of the abdomen, which were chiefly on the left side. Labored breathing began on the day of admission and he was unconscious from 4 o'clock in the afternoon until midnight, when he entered the Deaconess Hospital. Respiration was of the typical Kussmaul type; the pulse was of good quality and the systolic blood pressure was only 90. The lungs and abdomen were essentially normal. No patellar reflexes were obtained and there was no Babinski sign. The white blood count was 11,400. The eyeballs were soft. On admission the urine contained 2.9 per cent of sugar, 2 plus diacetic acid and the blood sugar was 0.46 per cent. The plasma carbon dioxide combining power was 9 volumes per cent. During the next twelve hours he received 430 units of insulin and the blood sugar dropped to 0.37 per cent. The plasma carbon dioxide combining power rose to 14 volumes per cent. However, the next day there was no improvement. The white blood count was 10,900. He was not anemic. The blood at all times was lipemic (table 2). The plasma cholesterol was 1,162 mg. on admission and fell during the next five hours to 1,020 mg. per hundred cubic centimeters. The total lipid values, on the contrary, rose to 8,032 mg. per hundred cubic centimeters, as did also the fatty acid value from 6,291 to 6,922 mg. per hundred cubic centimeters. The postmortem examination, April 11, showed an extensive septic pancreatitis with many areas of fat necrosis throughout the peritoneum in the neighborhood of the pancreas.

CASE 3.—A letter carrier was 41 years of age at the development of diabetes in January 1923. He had taken insulin since June 1923. He entered the hospital May 29, 1931, in profound coma. For three days he had not been well. Owing to his wife's illness, his son and daughter had been giving him his insulin. He had not complained of abdominal pain but had spoken of pain in the chest.

appropriately equipped for speculum examinations and all centers prepared for the study of every significant presenting case. For those who have Negro women to deal with, it is worth while to recall that the Cooperative Clinical Group investigation established the special importance of the control of the infectious colored female, in whom secondary infectious genital lesions are three and one-half times as common as in the white male, three times as common as in the colored male, and more than twice as frequent as in the white female. To point the moral of the potentially unmoral, so to speak, let it also be noted that the same study showed the married white woman to stand next to the male of either race and ahead of the colored woman, married or single, as a social factor in the spread of the disease.

In detecting syphilis in the woman, you will be brought into head-on collision with the adamantine inertia of a medical profession opposed through mental logic-tight compartmentism to the alleged degradation of motherhood by the suggestion of a shadow of venereal disease. Two blood tests in each pregnancy is the logical order for present knowledge. The first at the third month makes possible the treatment-before-the-fifth-month rule. The second at the eighth month detects the syphilis transmitted by the husband who stepped out during his wife's carrying of the child. Little short of a public educational backfire will remove this standing block of dead professional timber from the path of progress. The call, therefore, is for torches.

It is impossible to minimize the advance made by the demonstration of the effect of treatment for the syphilitic mother on the health expectancy of the child. The principles, astonishingly simple, are summarizable as follows: (1) recognize infection before the fifth month of the pregnancy; (2) treat every woman known to have had syphilis through each pregnancy, whether Wassermann positive or negative. Take blood pressure and test urine for albumin before each injection; (3) give in excess of 4 Gm. of neoarsphenamine, in a total of at least ten injections; (4) give also at least ten injections of a bismuth compound; (5) rely chiefly on the arsphenamine—end with it; (6) have cord and tenth day blood tests on the baby, not the former alone; (7) follow the child for at least two years, more if possible; have x-ray studies of the bones if suspect, regardless of blood examinations, shortly after birth.

The two weakest spots in our position with reference to antepartum treatment for syphilis are our relative ignorance or indifference to its possible effects on the mother, which have been lost in the chorus of hurrahs in behalf of the child, and our ignorance of the ultimate result for the child. We have been Wassermann bound in our outlook here. It will take years of persistent prolonged observation, utilizing especially Ingraham's contribution on the study of the bones, to enlighten physicians fully here and to clear the air of tosh. Meanwhile let us accept the reality of seminal transmission of the disease to the mother by the asymptomatic carrier-father; the worthlessness of history of infection in the mother; the benignity and obscurity of her still infectious course, as reasons for a thoroughgoing family follow up every time a syphilitic infection, acquired or prenatal, appears. Promise no woman cure, and control her every pregnancy if possible.

#### PROBLEM V. THE SYPHILITIC CHILD

I have but two further advances to record here. First, call again for torches to smoke the ultraconservatives out of their standing prejudice against the ars-

phenamines. Use tear gas on ophthalmologists who refuse to recognize that intensive arsenical and bismuth therapy similar to that for early syphilis or latency can save the involved eye and prevent involvement of the other. A group of competent observers from the late Derby and his associate Carvill, to Guy and to the most recent Cooperative Clinical Group demonstration under Cole's sponsorship, has proved it beyond a doubt. And, second, include fever therapy with malaria or typhoid vaccine systematically in the treatment of resistant prenatal syphilis. By resistant I do not mean mere Wassermann fastness, which is common and relatively unimportant, but all other refractory cases for interstitial keratitis and severe bone involvements, to juvenile dementia paralytica. As soon as possible after the recognition of prenatal syphilis, especially of the tardive type, examine the spinal fluid to forestall the onset of grave neurosyphilis by fever therapy, precisely as one does in acquired syphilis. Few rules will thwart more tragic consequences.

#### PROBLEM VI. NEUROSYPHILIS

It is obviously impossible at this point to review this colossal subject. You have heard me stress the preventive meaning of the routine spinal fluid examination in early and latent syphilis. "No rest without a spinal test"—my unacknowledged slogan baby. Always ask for a spinal fluid examination when a blood test, repeatedly negative, becomes positive or fluctuant in treated early syphilis; the same rule to be applied to latency, though with fewer positive results. There is no need to repeat after an initial negative in a patient first seen in latency; usually no need to repeat if the first test is negative after a year of treatment in early syphilis. Require a spinal test on every tardive prenatal or congenital syphilitic patient; a spinal test at least every six months in every neurosyphilitic under treatment until repeatedly negative. Have no serious anxiety about the spinal fluid picture within two years after malarial therapy in the patient with dementia paralytica. The same rule is good in tryparsamide therapy, continuously given, in both cases provided the patient is making symptomatic improvement. Remember that there are vascular neurosyphilitic patients who tend to have negative spinal fluids at all stages of the disease; that there seems to be even vascular or pseudo-arteriosclerotic dementia paralytica. Remember, too, that there can be false positive serologic reports on spinal fluids—technical from bad handling, biologic, I believe, in encephalitides.

Of the therapy of neurosyphilis, let us first say this. Ravaut, who brought asymptomatic neurosyphilis to light, died ten years too soon. He suggested and would probably have shown, though as a Frenchman he might have disdained statistically to prove, that a great deal of neurosyphilis recovers of itself; that even the paretic formula is compatible with a long, effective and healthy life. Just here is one of the rubs today; one of the flies in our unguentum tryparsamofebrilis, the current popular injunction for all neurosyphilis which does not yield a blank report sheet in the first two years. It is clearly proved that asymptomatic neurosyphilis tends to be withheld from symptomatic expression or cured by a prolongation plus some form of intensification of standard treatment for the disease. It is also pretty well proved that the incidence of asymptomatic neurosyphilis is reduced practically to zero by sufficiently intensive treatment begun early in the disease. The Zuhelle and Krechel figures show

than other conditions, such as perforating peptic ulcers or severe cholecystitis in three cases, and chronic infection located in the gallbladder with extension up the pancreatic ducts.

#### ETIOLOGY

In our series in case 1 gallstones and chronic cholecystitis afford a possible explanation for the pancreatitis. In case 2 the pathologist judged from the distribution of the infection along the course of the pancreatic duct that there had been an ascending infection of the pancreas. In the other two cases there is no clue from the postmortem examination as to the cause of the pancreatitis. The possibility of a blood-borne infection cannot be dismissed, although we have no blood culture or other evidence of a septicemia or bacteremia. It is to be noted that the pancreatitis in all four of these cases was of the septic or infectious type rather than a hemorrhagic pancreatitis. The ages of the subjects varied from 17 to 58 years. The presence of diabetes in the family was known in two of the cases but not known in the other two. In case 4 there was a marked alcoholic history, but the liver was less enlarged and showed no more extensive lipid infiltration than the livers in the other three cases.

The typical necrosis of acute pancreatitis depends on the activation of trypsinogen to trypsin. Ascending infections have been reported in which the active organism has been *Bacillus coli*, *Streptococcus faecalis*, *Ascaris* and other organisms. Proof of blood-borne infection as a cause of pancreatitis has been conspicuously rare. The classic case of Opie in which a gallstone was so impacted at the ampulla of Vater that bile was forced up into the pancreatic ducts suggests strongly that such invasion of the pancreatic ducts may be a cause. Any of the bile acids present in the normal bile possess the power of activating the trypsinogen to trypsin. When by reason of reverse peristalsis or duodenitis there is extension into the pancreatic ducts of the duodenal contents, the enterokinase may be assumed to cause an activation of trypsinogen.

Spasm of the sphincter of Oddi has been suggested by Archibald as a means of causing bile to enter the pancreatic duct. Flexner<sup>5</sup> was able to produce the worst cases of hemorrhagic pancreatitis by injection into the pancreatic duct of bile infected with *Bacillus coli*. Typical fat necrosis has been shown by Langerhans, Hildebrand and Flexner to be due to the action of the fat-splitting ferment present in pancreatic juice. The result is that the neutral fat of the fatty tissue is hydrolyzed by the lipase of the juice, permitting the formation of both soluble soaps and insoluble calcium soaps. It is well known that bile may activate the enzymes and cause destruction of the pancreas. However, Mann and Giordano<sup>6</sup> found in only 3.5 per cent of their experimental cases that it would be anatomically possible for obstruction of the orifice of the ampulla to convert the two ducts into a single channel and allow bile to pass into the pancreatic duct. Although acute pancreatitis could be produced by injecting bile into the pancreatic duct with a syringe, the amount of pressure required to bring about this injection exceeded 1,000 millimeters of bile in all but one case. Furthermore, in eleven cases of acute pancreatitis careful study showed that it was impossible for bile to be injected into the pancreatic duct. Therefore, entrance of bile into the duct by obstruction of the orifice is certainly not always and probably is seldom a cause of acute pancreatitis.

#### DIAGNOSIS OF PANCREATITIS AND DIABETIC COMA

Each of these four cases when first admitted to the hospital seemed to be typical cases of advanced diabetic coma. It is only during their course in the hospital under treatment that one might have noted points which suggested the presence of some condition in addition to diabetic coma. The points may be listed as follows:

1. Prostration more severe than one would expect with a blood pressure of over 100 systolic. This point was shown by the first case.

2. Failure to improve under adequate treatment. Case 1 presented no very great degree of hyperglycemia and yet large doses of insulin failed to improve the clinical condition. In case 3 a steady rise in the blood sugar occurred in spite of large doses of insulin. Similarly in case 4, in spite of chemical improvement, the general condition regressed with a rising pulse and repeated vomiting.

3. Sweating led to a mistaken diagnosis of hypoglycemia in one case and was present in a second case. A dry skin is typical of uncomplicated coma.

4. Sudden onset of extreme pain in the upper part of the abdomen, particularly if it goes through to the back, as an outstanding symptom, and rapid development of coma within six to ten hours suggest the possibility of pancreatitis.

5. Examination of the abdomen in an early stage before unconsciousness may show tenderness and spasm limited to the epigastrium and extending to the left of the midline.

Case 5 illustrates the difficulty of excluding acute pancreatitis in the presence of diabetic coma:

CASE 5.—A youth, aged 21, entered Deaconess Hospital May 31, 1936, with diabetes of seven years' duration. On the previous day the family physician had been called because of pain in the upper part of the abdomen. At this time the urine was practically sugar free. He had been taking 50 units of insulin a day for several years. The doctor found no cause for the pain in the abdomen. That night the condition rapidly became worse, and by 6 o'clock the next morning the patient was unconscious and entered the hospital five hours later, at 11 o'clock. There was profound unconsciousness, with a blood sugar of 0.56 per cent, and carbon dioxide combining power of 2 volumes per cent. With 320 units of insulin during the day and a large amount of salt solution he became conscious at 6 o'clock in the evening. At this time the liver was felt as low as the umbilicus and could be traced into the epigastrium. He complained of great distress in the upper part of the abdomen and into the back. He had vomited throughout the night. The vomitus obtained was clear green fluid such as has been described by Rienhoff and Lewis<sup>2</sup> and other writers. The abdominal examination showed the lower half to be soft, but the upper half was full, resistant and generally tender above the umbilicus. Extremely tender points could be elicited 1 inch to the left of the midline in the epigastrium, over the gallbladder and in the right flank. The tenderness over the pancreas was deep. The blood plasma was lipemic and the plasma cholesterol was 592 mg. per hundred cubic centimeters. The pulse rate had risen to 160. The white blood count was 12,600. The blood bilirubin was 0.9 mg. per hundred cubic centimeters. In differential diagnosis acute hepatitis, acute pancreatitis, perforated ulcer and gallstones were considered. Surgical consultants advised against operation. During the next week he had mild jaundice with fever for three days. The highest fever was 104 F., reached twelve hours after admission, although the rectal temperature on admission was 96 F. Roentgenograms of the gastro-intestinal tract and of the gallbladder by means of the gallbladder dye, however, were negative. The lipemia slowly disappeared.

#### CHANGES IN LIPID METABOLISM

There was definite fatty invasion of the liver cells in three of the four cases and lipid histiocytosis of the spleen in one.

5. Flexner, quoted by Archibald, E. W.: *Internat. Clin.* 2: 1, 1918.  
6. Mann, F. C., and Giordano, A. S.: *The Bile Factor in Pancreatitis*, *Arch. Surg.* 6: 1 (Jan. pt. 1) 1923.

During the winter of 1935 and 1936 this work was carried on with an evaluation of the work done by a number of state, municipal and private laboratories.

It should be mentioned that the work dealt with the use of serodiagnostic tests, and not with the tests used to govern treatment. In other words the quantitative tests were not evaluated, although the committee fully recognized the fact that quantitative tests are of more value in controlling treatment than the purely qualitative tests. There is a prevailing impression among many physicians that the symbols +, ++, +++ and ++++ represent a truly quantitative value in the serodiagnostic tests. This is not true, for there is a wide field beyond the four plus one which can be measured accurately only by determining the number of units of antigen employed to produce a reaction. A very considerable improvement in the serologic condition of the patient can usually be noticed while the ordinary qualitative test still gives a complete positive. The use of the quantitative test is especially urged in the tests on the spinal fluid as an index to the efficacy of treatment. It should be noted that the complement fixation tests lend themselves more readily to quantitative readings than do the flocculation tests. The committee has strongly recommended that tests be reported as negative, positive or doubtful.

The tests naturally fall into four divisions: the complement fixation tests, the flocculation tests, the microscopic tests and the tests on the spinal fluid. Most microscopic tests are modifications of the flocculation tests. They usually require a small amount of blood and the reading is done by means of the microscope. It is obvious that a test which can be done with a little blood drawn from the finger or ear is of great value in infants and stout women, and also on chancre fluid.

Attention should be directed to the Hinton "microscopic test," which in the second evaluation study gave 100 per cent specificity and 91.9 per cent sensitivity. Dr. Kline writes that a single diagnostic or exclusion test can be done on "as little as 0.15 cc. of blood collected in a narrow pipet," although he considers 0.5 cc. to be desirable. In our second evaluation study the specificity of the Kline exclusion test was not satisfactory in two of the three laboratories performing the test. The sensitivity of the Kline diagnostic test is lower than that of the exclusion test but the specificity is much higher.

In the first study a total of 14,238 samples of blood was examined, each serologist receiving comparable samples. In addition, 2,860 comparable samples of spinal fluid were examined. In the second evaluation study a total of 18,840 blood samples was examined. Because of the fact that in the second study there were thirty participating serologists with sixty performances, there was a division into four groups and the members of each group received comparable samples; but the samples sent to the four groups were from different patients and so were not comparable.

The tests were evaluated according to their sensitivity and specificity. It is obvious that sensitivity and specificity alone do not indicate the entire value of a test. Other factors which should be considered are the applicability of the test to other laboratories, the time consumed in making the test, the cost of the test, the amount of blood necessary and, lastly, the adaptability of the test, with certain modifications, to both blood serum and spinal fluid examinations. Could there be a general agreement as to the value to be given

each of these seven factors, the various tests could be evaluated definitely and decisively.

In the first study it was found that in general the tests showed a rather high specificity, although four of the participating serologists had a rating of less than 99 per cent, and only five had a rating of 100 per cent. The committee feels very strongly that any test which fails to show a rating of over 99 per cent specificity should be corrected, as it is believed that a false diagnosis of syphilis is, in the words of Moore, "a major calamity." The sensitivity of the tests varied to a considerable degree. The ratings given were from 65.8 per cent to 88.2 per cent. The committee feels that there is no choice between good complement fixation and good flocculation tests. It is obvious that the use of the latter is on the up grade and the use of the former on the down grade. But again complement fixation tests are the best quantitative ones.

A study of the tests used on the spinal fluid<sup>2</sup> has revealed that certain of the flocculation tests are not suitable, although some others are just as efficient as are the complement fixation tests. It is important to note that tests on patients who have been treated with malaria or with more than twelve injections of trypanamide or fifteen injections of arsphenamine show marked discrepancies in the reports of individual observers. Tests on the fluid from untreated cases of cerebrospinal syphilis show more uniform results. In general it should be noted that even in untreated patients the sensitivity of many tests is unsatisfactory. It is certain that tests on the spinal fluid must be chosen with the greatest care.

From the standpoint of specificity the committee found the following tests satisfactory: Brem, Eagle flocculation, Kahn diagnostic and presumptive tests, Kline diagnostic and exclusion tests, Kolmer, and Lufkin and Rytz. From the standpoint of sensitivity the leading tests are the Kahn diagnostic and the Ruediger tests, with the Brem and Kline diagnostic tests close behind.

A number of special problems were studied in the first project. Patients with leprosy yielded most divergent results.<sup>3</sup> Nearly 59 per cent of all tests performed on lepers yielded positive results. More or less similar results have been reported by other observers. Certain it is that the serologic tests for syphilis are of little value in differentiating syphilis from leprosy, except possibly during the period of septicemia. It would also seem that in suspected instances of leprosy in nonsyphilitic individuals a positive serodiagnostic test for syphilis may be of value as indicating leprosy. Malaria showed an unexpectedly high proportion of positive results, about 15 per cent. Further studies on malaria, as yet unpublished, have strongly fortified this statement. Tuberculosis, jaundice, malignancy, acute febrile conditions, pregnancy and menstruation did not affect the results.

The first study was an evaluation of tests done by expert serologists under relatively ideal conditions and it was expected to produce better results than would be obtained from state, municipal or private laboratories throughout the country. The second study was from such laboratories, and predictions proved correct.

paper can record. Have your serologic laboratory in close contact or under your own thumb. When you become too old to be virulent, retire. In all imaginable seriousness, I place the problem of headship, personnel, coordination, check from every angle, first among the problems of organized syphilology. Discipline among clinicians, physicians, health officers, technicians, non-medical, public health and social service personnel is indispensable—but discipline with inspiration, not subordination, as its keystone.

#### PROBLEM II. EARLY SYPHILIS

Two adequate systems for the treatment of early syphilis can now be issued in black and white for your public health and voluntary agents, including private physicians' reference and use: the British-Danish intermittent and the American continuous alternating. Of the two the Cooperative Clinical Group and the United States Public Health Service believe they have proved the alternating continuous to be the better. Certainly it is better than any American intermittent system which simply departs from the continuous by introducing rest periods and lapse into a system of drug, dosage and interval usage that should be continuous. Against American intermittent procedure of this lapsing type you should be warned and warned again. A simultaneous use of arsenical and heavy metal, as in the British-Danish, can permit short rest periods between double-deck courses. But an American alternating (single-deck) system cannot do so without a striking drop in effectiveness, a sharp rise in relapses, delayed serologic reversals, and irreversible positives. The American continuous alternating system has moreover the additional advantage of saving the difference between sixty-five weeks and ninety weeks, or about six months; and the League report concedes its probable greater effectiveness in keeping the patient in contact and control. Furthermore, intensive study of our American material has shown that under continuous treatment reaction to the arsenical and to the heavy metal is no different, or slightly less, than under the American intermittent systems; rest intervals do not increase the tolerance of drugs. Reaction data for the British-Danish or League intermittent system do not suggest any increased risk from their simultaneous and somewhat more intensive use of arsenical and heavy metal, or yet any gain from their rest periods. It is notable that jaundice seems to assume the character of a regional rather than a treatment system type of reaction. Do not therefore be deterred from the use of the superior continuity by fear of reactivity, for the consequences of noncontinuity are serious and the dangers of increased reactivity are nil. If anything, I give it to you as my personal impression that I would fear more the simultaneous use of arsenical and heavy metal than I would the continuity of a strictly alternate use of the two. There is good evidence that it is the heavy metal that raises the reaction tendency of a system of treatment rather than the arsenical, and the double load, especially in a continuous technic, needs fuller investigation.

The next point of considerable public health as well as individual significance is the difference between the treatment results obtainable in seronegative, seropositive and florid secondary syphilis by continuous and intermittent treatment. It is now apparent that the most refractory stage of early syphilis from the standpoint of control of relapse, serologic results and "cure" is the seropositive primary. Yet, in view of the slow progress being made in darkfield diagnosis, the inevita-

ble tendency of the uneducated public, to bring a self-concealing disease to late diagnosis and treatment and the serologic-mindedness of the medical profession, this is precisely the stage in which most early syphilis will tend to present itself for treatment for a long time to come. Let doctor and patient therefore be warned that this stage of the disease carried the worst, not the best, expectancy; that it can be brought up to the general level only by the use of some fifteen more arsphenamine injections than are called for in seronegative primary syphilis and ten more injections than are called for in a fully developed secondary case, with a corresponding increase in the amount of bismuth administered. The results for seropositive primary syphilis, even with the increased treatment described, are 20 per cent (65 per cent versus 85 per cent) below the best obtainable by treatment begun in the seronegative primary stage.

Fully developed secondary syphilis treated by intermittent or catch-as-catch-can methods yields even worse results than seropositive primary (58 per cent). But in compensation it appears that if secondary syphilis is treated by a continuous system the results quite closely approximate the best obtained in seronegative primary syphilis (81 per cent as compared with 86 per cent). The theoretical basis for this very interesting observation cannot be here discussed but is brought out in recent publications. It offers substantial encouragement for the individual who appears with secondaries in contrast with the comparatively unsatisfactory status of seropositive primary syphilis.

Let me impress you, then, once more with the importance of the continuous treatment of syphilis. Every study of every phase of the disease from chancre to late neurosyphilis conducted by the Cooperative Clinical Group has thus far shown its undoubted superiority to intermittence and the introduction of rest intervals or lapses in American systems of practice. Too much emphasis cannot be placed particularly on the concentration of effort that should be made on the first year of a syphilitic infection; on the first six months, the first three months if nothing better can be done—for every day of treatment continuity means less relapse, less resistant serologic reaction, less visceral, vascular and neurosyphilis for the future. With this final thump on the big bass drum, I turn to the arsenical phase of treatment.

Within the past few years several critically important facts regarding the arsphenamines have been established. First of all, these drugs are the infection controllers of our modern treatment for the disease, and their public health import is therefore paramount. No plan of treatment which excludes or substitutes inferior spirillicides or nonspirillicidal technics for the twenty-four to ninety-six hour surface sterilization obtainable by arsphenamine or neoarsphenamine has a right to consideration in early syphilis in the present stage of knowledge. I emphasize this advisedly because it is inevitable that methods with the drive of enthusiasm behind them, such as fever therapy of primary and secondary syphilis, will attempt to and have already thrust themselves between the established methods and their public health ideal. I hold no brief against the use of new drugs alone or in combination with the arsphenamines, but I insist that spirillicidal value remain the turnstile in the gate to therapeutic acceptance for use in early syphilis.

The critical point in the arsphenamine control of infectiousness lies between the fourth and the ninth injection. Treatment discontinued between the first and

ficity of well over 99 per cent and a sensitivity considerably greater than is usual at present. The work of numerous serologists shows that this is perfectly feasible.

It goes without saying that syphilis can often be diagnosed by other means than serologic. It may be true that during the early eruptive period the serologic test is much the best confirmatory evidence that we possess, but in the early chancre the darkfield in skilled hands is infinitely better. Here it would be well to point out that the mouth contains spirochetes very similar to *Spirochaeta pallida*. Parenthetically it may be remarked that it is conceivable that such organisms might be found on other portions of the body, if only for a short time. In late syphilis an x-ray study of the bones or the aorta may be invaluable. In neurosyphilis there are other valuable tests on the spinal fluid in addition to the serologic ones. It has been my experience that women who have been pregnant frequently show a negative blood serologic test. In this class the history of repeated miscarriages, or the finding of a syphilitic placenta, are of the greatest aid. It should be distinctly understood that I feel that every pregnant woman should have her blood examined for syphilis, preferably during an early period. These few examples by no means complete the list but they should suffice to show that serologic study is not the only way to diagnose syphilis. As is invariably the rule, a laboratory procedure is a good servant but a bad master.

Some may well inquire what can be done without serologic diagnosis of late syphilis. In the second evaluation study my service was being used to furnish donors for blood sent to one group of serologists. It was suddenly discovered that the blood reports furnished by our laboratory were absolutely without value. It was essential to continue the collection of specimens, and this was done on purely clinical and historical evidence. The percentage of positive reports on blood drawn from this series of donors was higher than on two other groups in which the collectors had the additional advantage of serologic information.

Lastly, one type of survey has been made as to the prevalence of syphilis in the United States, based on serologic observations. It is an uncomfortable fact that out of sixty performances in our second evaluation study no fewer than eleven reported a sensitivity of less than 50 per cent, and five reported sensitivity figures of less than 40 per cent. It is obvious that the survey figures must be regarded as entirely too low. The only way to remove this suspicion would be to evaluate the tests as performed at the time of the survey, and this is clearly impossible.

1911 R Street N.W.

**The Common Road Forks Only at Treatment.**—A clinic, let us say on aneurysm, is given on very much the same plan by both physician and surgeon, and their common road forks only at the post of treatment, where down one (and the longer) path beckon Valsalva, Tuffnell and Balfour to rest, a low diet and potassium iodide, and down the other (and shorter) Hunter, Corradi and Matas to some method requiring exposure of the lesion through an incision. The internist has learned that effective operative work cannot be done well for him by one who merely represents his hands, and he would not venture to refer his patients with obstructive jaundice or hematuria or pyloric stenosis to a mere operator who did not have the same knowledge of and the same attitude toward the pathological lesion of liver or kidney or stomach that he himself has.—Cushing, Harvey: *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

## MODERN CLINICAL MANAGEMENT OF GONORRHEA

P. S. PELOUZE, M.D.

PHILADELPHIA

Today we are to launch a nation-wide campaign against the genito-infectious diseases. It is to be expected that syphilis will receive most attention because it has been studied more closely and all those conversant with it and its therapy are sure that it practically can be stamped out or at least greatly reduced. If we allow this phase of the campaign so greatly to overshadow that far more prevalent disease gonorrhea as to make it appear a poor second in importance, we shall play our citizenry a rather sorry trick. My plea, therefore, is that the one receive as much attention as the other and that the seeming hopelessness of the one from the standpoint of disease reduction be viewed as a challenge rather than an excuse for neglect.

I am sure that, if physicians give proper attention to the barriers that in the past have stood in the way of success, the incidence of gonorrhea can be reduced far more than any one has thought it could be reduced. This will not be done by following either your particular plan of treatment or mine. We shall do it by analyzing the disease and its peculiarities, the human beings who have it and the medical agencies that care for it. This is not a battle to be won by air or by water. It is a warfare the success of which depends mostly on just what happens in those front line trenches where the infected patient and the doctor meet. We may reduce contacts in a measure by education, but history tells us that human beings are rather heedless of warnings, that they learn most from their own experiences. And, if they will turn toward sex outlets, as many of them will, the doctor stands at the crossroad and on just what he thinks and does depends a large measure of success or a wealth of dismal failure.

Gonorrhea is a disease that can be transmitted to others as long as there is a single gonococcus present. It is a disease the cure of which depends on the patient's ability to develop certain curative responses. These responses are not developed in patients who repeatedly consume alcohol or indulge in sexual excitement, and there are other factors that often retard them.

There is no treatment known today that lends itself to mass application that quickly renders the patient noncontagious.

In the male the disease is practically 100 per cent curable and in the female it should be almost as much so, so far as the eradication of the gonococcus is concerned. No one can predict just how long it will take each case to reach the point of cure.

In view of these facts our clinical problem is the same as holds with every other contagious disease: the avoidance of contagion-spreading contacts, and the cure of those who have the disease. In other words, it rests in the avoidance of sex contacts during the entire time the gonococcus is present, and no one who knows human beings will think that this is a small order. And, yet, every time it is successful a possible endless chain of infection is broken. Unlike some foreign countries, we have no laws compelling such patients to be treated. True, the boards of health of some of our states and municipalities can isolate the infected, but, in the main, *treatment depends solely on*

Read before the Conference on Venereal Disease Control Work, Washington, D. C., Dec. 28, 1936.

both blood and fluid throughout the sixty-five weeks' course makes a reexamination unnecessary, unless in the ensuing probation a blood test turns up positive. Spinal fluid examinations are unusable for interpretation unless they include cell counts and protein and colloidal tests; and the commonly linked phrase "blood and spinal fluid Wassermann," which one still hears from all quarters, should go into the discard. Knowledge of the grade of involvement of the nervous system, following Moore's and O'Leary's classification, is as important to the patient's future management and outlook as is the mere abnormality. Extended routine management will iron out the slight grades indicated by cell counts and weak positive serologic reactions alone. It is the involvements detected by four abnormal tests that must have special measures to do away with neurosyphilis as a late complication. For on those who treat early syphilis will rest absolutely, barring changes in the disease itself, the responsibility in treated persons for tabes, dementia paralytica and their camp followers. Granted the importance of the spinal test, how make it easy for doctor, clinic and patient? Lumbar puncture can be made an acceptable arduous procedure in our experience at the University of Pennsylvania, thus relieving clientele congestion and delay, by the following measures: (1) a reasonably humane and careful operator; (2) 3 grains (0.2 Gm.) of sodium amytal by mouth forty minutes before the test, after a light breakfast; (3) 2 per cent procaine hydrochloride skin and subcutaneous anesthesia, including infiltration of the ligament; (4) keeping the knees and chin as nearly together as possible; (5) keeping the upper shoulder in the same vertical plane with the lower; (6) talking to the patient before, not after; (7) using a conical-pointed small (Greene point) needle; (8) keeping the patient on his face for one hour after puncture, then sending him home with the advice to rest the day in bed; (9) giving another 3 grains of sodium amytal to the very nervous or overactive patient, to be taken at the evening meal. These steps make painless, almost reactionless lumbar puncture possible to any clinic or operator who deserves the name and do away, I feel, with the unwise exploitation of the much more difficult and risky cistern puncture, at least for any but the most specialized and expert.

The duration and nature of post-treatment probation and observation has been a bit enlightened for us in the past year. To me the curious thing is the way time stretches when one wishes to be absolute, from two to three to five years of observation and then to the individual indefinite reappraisal at such critical junctures as the pregnancy and each decade mark. Can we ever tell them to forget it? If their symptomatic and serologic course under continuous adequate treatment has been totally uneventful, not a ripple; if their five and ten year thoracic fluoroscopy is negative (mine would be repeated, I fear), and if she does not become pregnant—yes. But for every one else there is a perhaps and an individual decision, most especially for the pregnant woman, whether she is seropositive or seronegative.

#### PROBLEM III. LATENCY

Two thirds of my time and space have now gone to the prevention of this and all other categories of the disease. But with the new detection machinery in full movement, an enormous influx of seropositive latency is to be expected and must be evaluated and treated. Hospital, and outpatient and practitioner "pick ups" require (1) adequate complete physical examination,

not mere listening through the shirt and tapping the knees; (2) with a negative physical examination the beginning of treatment, not by the first arsenical "shot" one can reach, but with bismuth subsalicylate weekly, while one gains the patient's confidence and a spinal fluid examination. By the end of a ten injection bismuth course, patient and doctor will know where they are, conditions will not be materially obscured and may even be brought out, and the patient will have had a safe heavy metal preparation rather than the needless chance taking with arsphenamine in a subthreshold lesion, followed by therapeutic shock or paradox. If the spinal fluid is entirely negative, the Cooperative Clinical Group system for early latency (Moore as spokesman) calls for the standard treatment accorded to early syphilis so far as continuity and technic are concerned; but in latency after four years, twenty-four arsphenamine injections are enough, with sixty injections of bismuth preparations interspersed, and a repetition of the bismuth course once a year for a period ranging from three years to a decade. Many will oscillate between positive and negative, especially if enough tests are taken, for a long time. Only about 50 per cent of the patients will become lastingly seronegative. Pregnancy risks are reduced fourfold for the child; 16 per cent of babies apparently healthy at birth without treatment, 65 per cent with treatment, regardless of the amount given. The best results for the pregnancy come from the arsphenamine; for the individual adult with latent syphilis, from the heavy metal given over a period of years.

#### PROBLEM IV. THE SYPHILITIC WOMAN

For two reasons I would place the syphilitic woman first rather than fourth among the modern problems of syphilis. Infectious early syphilis of a woman's genital tract is the *terra incognita* of the public health aspect of the disease. The relatively more benign and inconspicuous course of the whole infection, which Warthin rated as in her almost a disease in a different animal species, fills the terrain with the unexpected and unpredictable and makes epidemiologic and therapeutic certainties rare indeed.

Perhaps it is a lingering trace of chivalry that makes my medical students have such difficulty in realizing that marriage has nothing to do with the transmission of syphilis—at least not marriage *de jure*. It is marriage *de facto* that counts—and not even that, in these days of petting and necking (if those terms are not already antiquated). Every woman therefore is suspect as a carrier of syphilis, even though she is a virgin with an unruptured hymen. I refrain from citation at this point of the evidence for an impression that the vagina is being more often sidetracked in favor of pederasty and sodomy, under the combined influence of fear of pregnancy and fear of venereal disease. Nor is it possible as yet to evaluate the observations and suggestions of Coutts and of Benech and Spillman on the human vagina as a passive carrier of *Spirochaeta pallida* in the asymptomatic syphilitic prostitute. There can be no doubt of the importance of experimental study to determine the fate of passively carried organisms; of technics of local prophylaxis as part of contraceptive measures; of the effect of bismuth "plugging" and of the arsphenamines administered to passive carriers; and, above all, of routine speculum examination of all female contacts of persons with syphilis, to the whole problem of the control of woman's share in the dissemination of the disease. Every clinic should be

In campaigns such as this there is great danger that more attention will be given conditions at the top than at the bottom. Unless we give first thought to the building up of an interested, satisfied personnel among those who come into direct contact with the infected patient our efforts will meet with limited success. Under other conditions the percentage of lapsed and indifferent patients constantly will resow the soil that we so earnestly have tried to clear and we shall look in vain for an improvement in future incidence figures commensurate with the time, thought and financial expenditures given to the present campaign. I therefore urge you who are public health officials that before you hand down too many orders from your points of greater vantage you take some heed to the development of an army that can and will carry them out.

#### SUGGESTIONS

In the building up of this first line of defense, certain clinical procedures are of the utmost importance aside from the reporting and following up delinquent cases and those aspects that so fitly are considered as coming under the social service aspects of disease control. Thus, confining myself to the purely medical side of the question, I would make the following suggestions:

1. A uniform history blank should be used throughout the country. There could be no better time to foster uniformity than the present, and the advantages of it are outstanding. With such uniformity it would be a rather simple matter to decide on the comparative values of the different types of treatment now in use. Also, the study of such histories would do much to teach those using them far more about the disease and the things that are or are not good for it, a gain that would reflect itself in many good ways.

2. The one in charge of a treatment center should be really interested in the disease. Lack of such interest makes for poor work and for poor personnel cooperation. It does little toward disease reduction.

3. Younger men in such dispensaries should be compensated for the services rendered. In dispensaries of size, this probably should fall on the hospital but, if proper thought were given to possibilities for just revenue from the dispensary itself, this rarely need be a matter of direct cost to the hospital. Hospitals that have been in the habit of charging small fees for patients able to pay them merely would have to apply the receipts from this one dispensary to the dispensary rather than to their general funds. In smaller dispensaries and in rural communities, other means would have to be devised.

4. There should be a close alliance between the chiefs of dispensaries, their assistants, their local and state boards of health and the United States Public Health Service as a means of making each one who treats the disease feel that he is a part of a campaign of disease reduction and that some one cares.

5. So far as such a thing is possible, efforts should be made to carry out an educational campaign among those who treat the disease. In this way interest will be stimulated and better work will result. Also, there would be built up a degree of sanity regarding the disease and its treatment that would reduce to a minimum the dangers of the exploitation of treatment methods that have little or nothing to offer. Such things retard advancement and often work to the harm of thousands of patients.

## THE VENEREAL DISEASE CONTROL PROGRAM IN KANSAS

EARLE G. BROWN, M.D.

TOPEKA, KAN.

In accordance with state laws, syphilis and gonorrhea were made notifiable diseases at the quarterly meeting of the Kansas State Board of Health in January 1914. Of especial interest, therefore, is that portion of the report of the secretary and executive officer relating to these two diseases at the annual meeting on June 6, 1914, as follows:

Our statistics are so few as to be of little consequence, but I cannot forbear a few words on this subject. Under the new Morbidity Report Regulation venereal diseases are made notifiable with the provision that all reports of cases by attending physicians shall be made on special report card directly to the State Board of Health, and providing also that the name of the patient need not be given, but only a serial number. Many reports have already come in from physicians. It was not expected that any quarantine or any publicity be attached to this procedure, and as you know, the results can only be statistical. . . . Many physicians, and indeed this is the average, have neither means, time nor equipment to provide their own laboratory diagnosis in these cases, and even if they were able to do so, many of this class of patients are either not able to or will not afford the fees demanded for this work. Obviously, the welfare of the public, of both patients and innocent persons who may suffer, demands that the state should provide free Wassermann and complement fixation tests. Progress in venereal disease control depends upon the education of the individual, and primarily upon the education of the infected individual, whom we can only hope to reach through being able to offer such free scientific and bacteriological information which will instruct him, through his physician, when he may relax vigilance in those measures which are necessary to prevent transmission of his infection.

In the following three years no comment was offered by the secretary regarding the problem. Morbidity records show occasional reports of cases of gonorrhea and syphilis. It is of interest to note, however, that from May 1916 to April 1917 inclusive, a period of twelve months, physicians reported only sixteen cases of syphilis and fifty-five cases of gonorrhea.

With the active participation of the United States in the World War, a new interest developed. At the quarterly meeting of the board on Nov. 2, 1917, the secretary reported that much of the session of the American Public Health Association at Washington, the previous month, had been given over to "a discussion of ways and means for control of venereal diseases, particularly as they relate to the civilian population in or near the various military reservations of the United States." Consequently, a resolution and proposed regulations for the control and suppression of gonorrhea and syphilis within extracantonment zones were introduced and adopted by unanimous vote.

At the third quarterly meeting on March 29, 1918, the venereal disease regulations in force were amended and city and county health officers were authorized to "make examinations of all persons reasonably suspected of having syphilis in the infectious stage or gonococcus infection," and to isolate such persons if such isolation was necessary to protect the public health.

On May 4, 1918, the War Department assigned an officer of the Medical Reserve Corps "for duty as epidemiologist and to have charge of the control of venereal diseases." At the annual meeting in June the

Read before the Conference on Venereal Disease Control Work, Washington, D. C., Dec. 28, 1936.

that simultaneity as well as the alternating continuity of the Cooperative Clinical Group system bring this to pass. The preventive road therefore lies straight before you and with apologies to Kipling "let a good spring sweat come o'er you," as you follow it.

Late neurosyphilis, soon to be almost the only island of private practice, albeit a lush green one, in a swelling sea of public health, needs only this comment. The relative values of mechanized, electrified, proteinized and malarialized fever therapy are in the balance. I place malaria first, believe the best opinion, experience and time-accumulated evidence supports it. "Mene, mene!" is written on the wall for the electrical stuff, or perhaps it is "tekel, upharsin." Every little physical therapist and every little quackster now has his diathermy unit. Riding two summers ago along the streets of a large Western city, I found them rivaling the fecalophiles and colon irrigationists in the gleaming virtuosity of their advertising displays. I plead with science and the public health to step in here and by the controlled particularity of their practice and research effort to clean up the confusion as rapidly as possible. Even the simpler modes of fever therapy are not affairs for the inexperienced. They endanger life, inspire false confidence and can be touted by the rash and foolish to the actual hindrance of progress, as in the present unrestrained advocacy of their use in the treatment of infectious syphilis. Let me close the topic by saying that tests for fields and visual acuity should be made before tryparsamide as well as after it, for the first eight weeks, even in rich patients who get the poorest care. Tryparsamide following fever therapy is a real help, just as fever, especially malaria, will, as Solomon recently pointed out, suddenly clear up a fluid that has for months and years completely resisted tryparsamide. Otherwise the two still run pretty much neck and neck as regards ultimate efficiency. All of us await with great interest the complex interpretations involved in O'Leary's study of Cooperative Clinical Group results, which seem to revive the ghost of intraspinal therapy as genuinely effective in comparison with malaria, and so on, even in the haze of uncertainty as to what mere prolongation of treatment, time and biologic defense can do for neurosyphilis.

#### PROBLEM VII. REACTION CONTROL

I have rather unwisely left this vital topic to the cursory treatment of a hurried close. Let us make it a matter of do's, rather than don'ts.

*Some Do's.*—1. Take minor reactions and discomforts seriously. They spoil attendance, wreck follow up and results. Try to circumvent pain, keep tools in shape, insist on skilled personnel, hold down the pace.

2. Instruct the patient about fore and after care, in writing if possible; light meals before treatment, low carbohydrate, low roughage, high fat, high protein diet; after the arsenical a rest and cathartic; after intramusculars, massage, hot applications, exercise. Have him report gastro-intestinal upsets, dark urine, light or black stools, itching, rash, fever, pain, without delay.

3. Take every precaution against blunders; retain and read ampule labels before injection, watch the drug dissolve; make aspiration, not injection, the first movement with the needle and syringe. Shoot slower than you think you should, stick to and in the upper outer quadrant of the buttock, large or small, and then massage long and firmly, yet longer and more firmly.

4. Establish the inspection of the patient's face, mouth, wrists and elbow bends, ankles if possible, as

preliminary to every arsenical treatment in clinic and practice. Work with the patient's neck exposed. Feel the butt and acknowledge your handiwork before each intramuscular injection.

5. Put every patient through certain routine questions, oral or written, before each intravenous treatment: thirteen of them covering intercurrent infection, warnings of purpura, dermatitis, nitritoids, jaundice, symptomatic progress.

6. Halve the average therapeutic for the first dose; pick the drug with thought, to avoid shock and paradox; with arsenicals, when in doubt *don't* until you can get advice; use much calcium orally and intramuscularly and dextrose intravenously when in a tight place; don't rely on patch tests.

#### CONCLUSION

Gentlemen, as we step into the pressure reducing chamber, let me say that I had an eighth problem to present to you. While the door closes may I remark that all that has gone before is reduced to nothing unless you bring your patient to an unswerving allegiance to yourself and all you represent and advocate, by such a humanity of approach, such an anticipation of his needs and problems as a being like yourself, as only the heart can compass. Injections of chemotherapeutic agents are merely mediated by the hand and head. Effective treatment for syphilis may indeed be mechanized to a certain perfection by knowledge. But the uprooting of the disease from its hold on humanity is done by the eye, the voice, the understanding and sympathetic spirit, without which all our much gathering of knowledge is but the unliving dust.

3800 Chestnut Street.

## THE SERODIAGNOSIS OF SYPHILIS

H. H. HAZEN, M.D.

WASHINGTON, D. C.

In August 1934, at the request of the American Society of Clinical Pathologists, the United States Public Health Service sponsored a study for the evaluation of serodagnostic tests for syphilis in the United States. A committee consisting of two syphilologists, two clinical pathologists and one representative from the Public Health Service was appointed by the surgeon general of the service. The first report was read in June 1935 and was published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and in *Venerel Disease Information*.<sup>1</sup> This study consisted in an evaluation of tests performed by the following serologists: Walter V. Brem, Los Angeles; Harry Eagle, Baltimore; William A. Hinton, Boston; F. M. Johns, New Orleans; Reuben L. Kahn (performing the Kahn standard diagnostic test), Ann Arbor, Mich.; B. S. Kline (performing the Kline diagnostic test), Cleveland; John A. Kolmer, Philadelphia; M. B. Kurtz (performing the Kahn presumptive test), Lansing, Mich.; N. H. Lufkin and F. Rytz, Minneapolis; Charles R. Rein (performing the Kline exclusion test), New York; E. Henry Ruediger, San Diego; Emil Weiss, Chicago, and Capt. W. C. Williams (U. S. Army), Washington, D. C.

Read before the Conference on Venereal Disease Control Work, Washington, D. C., Dec. 28, 1936.

A.* **103**: 1705 (Dec. 8) 1934; **104**: 2083 (June 8) 1935; *Ven. Dis. Inform.* **16**: 189 (June) 1935, reprint 52.

Wassermann test to sign a blank stating that they were unable to pay for the service and also that they were residents of the state of Kansas. However, no further limitations were placed on the work of the laboratory.

The foregoing summary of venereal disease control work from 1914 to 1935 has been presented in order that comparison may be made with the proposed program of the future. As a result of funds allotted to the Kansas State Board of Health by the United States Public Health Service under the provisions of the Social Security Act, a program is in process of development with a full-time director in charge.

The director is a doctor of medicine who graduated nine years ago and, following completion of his internship, was in private practice several years. He attended the short course in public health at Vanderbilt University in the spring of 1936 and for his field work was assigned to one of the Tennessee counties, where an unusually efficient venereal disease program had been an important part of the unit's activities for many years.

The director assumed his new duties on July 1, 1936, and during that month under the guidance of Surgeon O. C. Wenger made a study of the problem from existing records and also appraised the work of the three clinics. In the following month, on the recommendation of Dr. Wenger and with the approval of the surgeon general, the director was given a ten day training course in the diagnosis and treatment and administrative work in venereal disease control at the United States Public Health Service Venereal Disease Clinic at Hot Springs, Ark.

Dr. Wenger, following his trip to Kansas, made the following recommendations:

1. Free serologic service to all physicians by increasing the laboratory staff.
2. The addition of medical and social personnel at the three clinics; also additional equipment if needed.
3. Free neoarsphenamine and heavy metals to physicians for indigent patients.
4. Standard medical record for use in all three clinics.
5. The use of the U. S. Public Health Service classification for syphilis in all clinics to assure better material for study.
6. That an educational program for physicians be started so that they will report their venereal disease cases.
7. When more full-time health units are established throughout the state, that the venereal disease program be included.

The surgeon general for the fiscal year 1937 has approved a budget for the Division of Venereal Diseases of approximately \$10,000, which includes, of course, the salary and travel allowance for the director. Some equipment has been purchased for the laboratory and an additional technician employed. The restriction on Wassermann tests for pregnant women has been lifted.

Assistance has been given to the Kansas City clinic through the payment of small salaries to the part-time clinic director and part-time clerk. One nurse has been employed and assigned to the Kansas City clinic, and the director of health reports the discovery of an average of one new case a day since her employment. A second nurse has been employed and assigned to the Wichita clinic. Request has been made of the surgeon general for the use of lapsed funds for the employment of an investigator for the Topeka clinic for the six months beginning Jan. 1, 1937. Neoarsphenamine is supplied to the Kansas City and Wichita clinics and also will be supplied to physicians for the treatment of indigent cases, in addition to heavy metals.

Request has also been made of the surgeon general for the use of lapsed funds to provide each practicing physician in the state a one year subscription to *Venereal Disease Information*. We have been informed that the request will be approved. It is believed that the physician's interest in the venereal disease problem will be materially stimulated by reading this valuable publication.

During the month of November a resurvey of venereal disease prevalence was completed in the twenty-two counties originally surveyed in 1927. The statistical information, of course, has not yet been compiled. It is interesting, however, that an almost complete return of questionnaires has been received from the physicians.

Under date of Aug. 25, 1936, a request was made of the president of the Kansas Medical Society that a committee be appointed to cooperate with the state board of health in the venereal disease program. The request was granted and a committee of nine appointed, under the chairmanship of a Topeka urologist, and the director of the Topeka clinic. The committee has held two meetings and in addition the chairman has conferred on numerous occasions with the director.

The reaction of Kansas physicians to the proposed program, I believe, is shown by the letter of the president of the Kansas Medical Society to the members, which appeared in the December 1936 journal of the society. It was in part as follows:

It is clear that the next few years will bring about one of the most extensive programs on the subject of venereal disease that has ever been attempted. Dr. Thomas Parran, surgeon general of the United States Public Health Service, has chosen this as the foremost activity of this organization and has requested and received the support of organized medicine in this regard. With a merger of public health and medical forces, there is every possibility for gonorrhea and syphilis to be placed in the category of controlled diseases.

Extensive activity in this direction has already begun in Kansas. At a recent conference . . . arrangements were completed for appointment of a Society Committee on Venereal Disease, and for coordination of Kansas venereal disease programs under its direction.

This committee has been appointed and has already held one meeting. Its present program consists of preparation of a scientific brochure on treatment of gonorrhea and syphilis, which it is hoped will provide a practical desk reference for physicians; arrangements for a scientific symposium on this subject, to be held within the near future in each of the councilor districts; presentation of a venereal disease section in the *Journal*; sponsorship of a scientific information bureau; wide lay educational activities through the medium of the county medical societies, and economic plans for the treatment of indigent syphilitics.

Kansas is fortunate in having a state board of health which is practical and efficient in its viewpoint on all matters within its jurisdiction. . . . We urge, therefore, that all county medical organizations discuss fully all bulletins issued on this subject; that they cooperate extensively with the Kansas State Board of Health and this committee in all of their programs, and that they adopt syphilis and gonorrhea as one of their major responsibilities and a basis for future activity.

Thus the new venereal disease program is under way. Already certain recommendations made by Dr. Wenger in his report to the surgeon general have been complied with. Additional serologic service in the diagnosis of syphilis has been provided; certain personnel has been made available to the Kansas City and Wichita clinics, and free neoarsphenamine and heavy metals are available to the clinics and to private physicians for the treatment of indigent persons with syphilis.

Comparable samples of blood sent to a control laboratory, where the test was performed by the originator of the method, did not produce the same reports in many instances. A number of laboratories reported a sensitivity in the thirties, whereas a control laboratory reported from fifty-nine to eighty-nine per cent. Not enough laboratories reported on the Eagle, Hinton, Kahn presumptive and Kline exclusion tests to enable the committee to draw any conclusions, although in all instances there was marked similarity. The laboratories using the Kline diagnostic test varied much less from the control than did the laboratories performing the Kahn diagnostic test and the Kolmer test.

In the evaluation study of the state, municipal and private laboratories the specificity varied from a low of 91 per cent up to 100 per cent. In general it may be remarked that the specificity figures of the laboratories were better than their sensitivity figures, although twenty-five performances recorded a specificity of 99 per cent or lower. Here one performance gave a new low record of 34.1 per cent, although other methods employed on comparable samples gave as high as 91.4 per cent. A total of eleven performances showed a sensitivity of less than 50 per cent, which is excellent proof that the methods of these laboratories sadly need correction.

In this study there were two objects, one to evaluate state, municipal and private laboratories, and next to evaluate the applicability of tests for use in other laboratories.

The value of serodiagnostic tests in certain stages of syphilis needs special consideration. In the primary stage the committee found the greatest difficulty in determining how long the initial lesion had been present and so could give no results as to how early the serodiagnostic tests became positive. The general average was 72 per cent. This study is being extended and the committee hopes that ere long it can reach definite conclusions. The use of "follow up" serologic tests is strongly urged in all instances in which there is a darkfield and serologic negative sore that is suspected of being a chancre.

In the eruptive stage of secondary syphilis the test was positive in practically all instances.

In late syphilis, tests evaluated in the first study were positive in 74 per cent of the patients; these patients had had varying amounts of treatment, and it is probable that some were really cured and that others were rendered serologically negative as the result of therapy.

It is obvious that a negative finding does not exclude either primary or late syphilis, although a negative sensitive test does nearly exclude early secondary syphilis. In the absence of leprosy, yaws or malaria, the occurrence of two or more reliable positive serodiagnostic tests means syphilis. Unfortunately the reliability of the work done is not uniform in all laboratories. The percentage of false positive reactions, especially with certain very sensitive tests, is too high, and the sensitivity figures of some tests are often too low. With the object of improving these conditions the committee recommends that a permanent opportunity be afforded the state laboratories to have their tests evaluated by the Public Health Service. The committee further recommends that the state laboratories extend the same privileges to other laboratories within their jurisdiction. It is of the utmost importance that the serodiagnostic tests for syphilis be above criticism, which is certainly not true at the present time. In most cities entirely too

many laboratories are bidding for the work. When relatively few tests are performed in a laboratory there are certain results: an increased expense, an infrequent performance of the tests and, too often, neglect of standardization. It is probable that hospital and private laboratories should be afforded the opportunity to have their results checked by the state laboratories, and that if they do not do this voluntarily they cease performing such tests. In other words, it may be necessary to license them. Undoubtedly the question can be raised as to the propriety of the government, state or municipality performing serologic work in syphilis without charge. It is my firm conviction that, if physicians are to engage in a successful campaign against syphilis, free serologic work must be done even though occasionally advantage is taken of it by a designing patient or physician. There are millions of syphilitic persons who simply cannot afford to pay the charges for serologic tests. At the same time the performance of hundreds of free tests is a serious financial drain on a laboratory and, as free tests must be reliable, it would seem only just to subsidize laboratories that perform free tests in a competent manner. It is possible that this can be done under the provisions of title VI of the Social Security Act. It is the further object of the committee to study certain special problems of serology, both of the technic of the tests and of the value of the tests in syphilitic and nonsyphilitic conditions.

Certain special problems deserve, or are receiving, special study:

The cost of the tests varies markedly. Naturally the cost of a test should be the last consideration, but it may make a considerable difference in a health officer's budget. The cost is determined by (1) the overhead of the laboratory, (2) the cost of equipment; (3) the salary of technicians and (4) the cost of supplies for the tests. It is obvious that, if a test takes but a short time to perform, the cost of the technician's time will be less. The cost of materials for performing 500 complement fixation tests a week is variously estimated at from \$7.50 to \$15, while for flocculation tests it ranges from \$0.25 to \$1. In addition, for this number of complement fixation tests from two to three technicians are employed, while for the flocculation tests only one is necessary. In a busy state laboratory the exclusive use of flocculation tests might save some \$350 a month. These figures are based on the estimates of the serologists who were engaged in the first evaluation study.

As regards time, the complement fixation tests require from seven to twenty-four hours, while the flocculation tests can usually be done in from one to one and one-half hours. However, Hinton states that his test requires eighteen hours.

The future of serology for the diagnosis of syphilis is an interesting subject for speculation. Judging from the present trend the flocculation tests will probably displace the complement fixation tests for the diagnosis of syphilis. Where but little blood is available, as in infants, slide microscopic tests requiring but a few drops will be available. Similar tests of great delicacy may also be used on a small quantity of chancre fluid. It is possible that chancre serum will show a positive test while the blood serum is still negative. For controlling treatment, quantitative tests on both the blood and the spinal fluid will be employed. Apparently these will be complement fixation tests. In addition the majority of laboratories will perform tests with a speci-

467,146 doses were distributed during the first ten months of the present year at an estimated cost of approximately \$20,000.

Consultation service is provided through clinics to which patients may be sent for review of their syphilitic diagnosis, and through the appointment of seven part-time consultants. Each of the latter has had special clinical experience in syphilis and, besides supervising clinic activities, is available on request for private consultation.

Under the State Sanitary Code the physician must report by name each syphilis patient who lapses treatment while still in the infectious stage of the disease. This regulation implies an obligation on the part of health officials to find delinquent patients and to see that they are returned to treatment. Except in large cities, facilities for rendering such service are not as yet fully adequate and remain to be developed when trained personnel can be found for the district staffs.

Keeping the medical profession informed as to modern and generally accepted methods for the diagnosis and treatment of syphilis is a proper and necessary health department function. This phase of the New York State program has lagged behind other activities, but informative material for physicians is now in preparation. This material includes a short reference pamphlet describing briefly the continuous method of treatment and giving criteria for the release of patients as arrested or cured. It is also planned to offer without charge to each physician in the state a subscription to the United States Public Health Service *Venereal Disease Information*. In cooperation with the public health committee of the state medical society, county medical societies are to be asked to hold special meetings on syphilis for which speakers and motion pictures will be supplied if desired.

#### AID TO CITIES WITH APPROVED CONTROL PROGRAMS

A special morbidity survey made in April 1935 revealed the fact that of 18,960 syphilis cases under treatment in New York State outside of New York City 8,859, or 46.7 per cent, were being cared for at clinics. This proportion was an increase of 16.8 per cent since a similar survey in 1930. These figures show the importance of the public clinic and the necessity of insuring their effective operation from the standpoints of diagnosis, treatment, follow up and investigation of sources and contacts.

The New York State Department of Health has established a system of granting aid to cities in which health officials agree to carry on approved syphilis control programs. The standards to be maintained if approval is granted cover other features of the program such as record keeping and case investigation in addition to clinic service. Standards for approved clinics, however, contain specific reference to such matters as room space and lighting, equipment, waiting room, and clinic hours. They also provide that a physician shall be in attendance throughout each clinic session, that the plan of treatment shall be continuous, and that each new patient shall have a complete examination. Whenever practicable, a spinal fluid examination is to be performed before the patient is discharged as arrested or cured. Facilities for the follow up of delinquent patients and for the examination of contacts must be provided.

Financial aid from Social Security funds is now being given to fourteen cities in which health officials

have agreed to carry on approved syphilis control programs, and similar assistance is being given to a village and the surrounding territory of a densely populated area. Negotiations are under way for offering aid to at least five other cities which, if successfully completed, will bring about a situation whereby every city in the state of more than 40,000 population is receiving assistance from Social Security funds.

Because of the failure of enabling legislation, we are not in a position to make grants in aid to cities directly. Assistance is rendered by employing full-time state or part-time medical or nursing personnel and assigning persons so employed to work under the direction of city health officers; also equipment and supplies are purchased by the state for municipal use. Although matching by new appropriations has not been strictly required, such appropriations have been encouraged and the maintenance of city appropriations for venereal disease work at their present level has been insisted on.

Municipal syphilis control programs are supervised by the department's central office, by district state health officers and by part-time medical consultants. There are two physicians on the central office staff both trained in syphilis clinically and both graduates of a school of public health. These physicians have visited all cities where aid has been granted or contemplated and, with the assistance of a consultant nurse, have taken steps toward the organization of local programs. Each medical consultant visits regularly the clinics in the territory he serves and advises clinic physicians to general methods of therapy as well as the treatment of individuals. District state health officers have supervision of public health activities, including syphilis control in the areas in which they serve.

#### CASE INVESTIGATION AND FOLLOW UP

Original plans for the New York State syphilis control program called for the investigation of each early and potentially infectious case. The term "potentially infectious" was defined as including the following types of cases regardless of the presence or absence of visible lesions:

1. All patients with acquired syphilis who have received less than twenty injections each of an arsphenamine and a heavy metal, or equivalent treatment, until five years has elapsed since onset.
2. All female patients with acquired syphilis who have received less than twenty injections each of an arsphenamine and a heavy metal, or equivalent treatment, until the menopause has been reached.
3. All patients with early congenital syphilis or showing open lesions.

So many syphilis cases, in large cities literally thousands, fell into this classification that it was not practical to require the examination of all contacts or to attempt to find all sources of infection. Efforts have been made to determine the source of infection of each early case in certain cities and to locate and to have examined contacts both prior and subsequent to infection.

Case investigations of this kind have been found to be time consuming, laborious and often disappointing, particularly in large cities. We have not been able to duplicate in cities the success of Brumfield<sup>2</sup> and others in finding sources in rural or semirural areas. Special efforts have been made to find the source of infection

2. Brumfield, W. A., Jr., and Smith, D. C.: Transmission Sequence of Syphilis, *Am. J. Pub. Health* 24: 576 (June) 1934.

the patient's willingness to take it. Predominantly the reduction of disease spread from infected individuals depends on control by force or persuasion. As the former is seldom possible, the field narrows to just what a medical mind can do with the mind of the infected patient.

Faced with such a clinical problem, we would do well to analyze our front-line trenches to see what the outlook is and what can be done to better it. For, in the final analysis, we are embarked on a campaign of selling good conduct to the patient and keeping it sold, until he no longer has the disease. No industrial concern would pour money into a nation-wide selling campaign without a most careful study of the need for the product, the men who were to sell it and the incentive that could be given them for the selling. We would do well to profit by their experiences.

What is the character of our market, as the industrialist would say? Well, it largely is a cross-cut of pleasure-loving American youth and it rather sharply divides itself into three groups.

Group 1 comprises those conscientious individuals who deplore the plight in which they find themselves and carry out every medical instruction to the letter.

Group 2 is composed of those who are by nature so shiftless that they do as they please.

Group 3 is by far the largest one and is composed of many individuals with group 2 tendencies and an overwhelming proportion of human beings who can be encouraged to follow the light if some one takes pains to show them the light.

About group 1 physicians need have little anxiety so far as disease cure and transference are concerned. We cannot view group 2 with so much complacency; they are active disease spreaders and, if they cannot be persuaded to join group 3, they should be denied human contacts until cured. Group 3 is our real campaign challenge and on just what happens to it hangs the success or failure of all our efforts.

For certain reasons inherent in human beings, the management of gonorrhea in dispensary practice differs widely from that of the usual private medical office. We may talk as we wish about "all men being created free and equal," but no one knows better than the physician who treats patients afflicted with gonorrhea that they are not all similarly endowed with those qualities which make them good patients. It is just this difference that makes the mass treatment of gonorrhea, as such treatment usually is carried out, one of the most discouraging of clinical efforts. It is the combination of this difference and the existing social attitude toward gonorrhea that make its dispensary treatment one of the most thankless and least inspiring of all medical experiences.

In our consideration of the therapeutic attack on this disease we largely have developed the habit of thinking most of the things we lack. Because a few treatments of one type or another do not render the patient incapable of transferring the disease to others, as is the case with syphilis, we have developed somewhat of a defeatist attitude toward the problem of its incidence reduction. Often we have expended much of our effort in phases of the subject which, though interesting and valuable, do not encompass the fields wherein success or failure lies.

We have done much in fact finding and have compiled an array of figures that show, in a measure, to what an appalling extent the disease infects our population. We have indulged in less general propaganda

of an educational sort, but, even here, we have been by no means idle, despite public lethargy. We have studied the disease from many angles until today our knowledge of it and its vagaries is far greater than is the case with many other diseases. But in the domain of treatment we almost ceaselessly have argued about little things; often we have been in error, at times ridiculously so. Usually we have been so because we did not make use of our knowledge of the disease itself but followed the lure of the easy and the immediate for a disease that refused to lend itself to either.

I have spent many years in close contact with the gonorrheal patient and his mentality in both private and dispensary practice and I am not so doubtful about what usually can be done with him from the standpoints of disease cure and conduct control as I am about finding those who conscientiously will try to do it. In this view I am not giving criticism to the medical profession or to those high-minded individuals who aid it in one way or another. I criticize a social attitude that could be so blind in the face of so great a menace as to offer less than no incentive for either. For, other than the personal knowledge that one is of service to mankind, there is no incentive. Aside from the general social attitude there usually is an unhealthy hospital attitude toward the work, the quarters are inadequate and poorly equipped and, no matter how carefully and conscientiously the work is carried out, no one seems to care. It is gloriously to the credit of the workers that they worked at all.

With but a pathetically small number of dispensaries where gonorrhea is treated, there is no waiting list of doctor applicants. It is not a question of whom they will let treat gonorrhea but whom can they get to do it. Usually they limp along with from one half to one third of the physicians that would be needed if any real effort were to be made toward patient cooperation. One of the most outstanding facts in gonorrhea control and cure is that it depends greatly on the nature of the doctor and patient contact. And, unless a way is found to arouse medical interest and add incentive for the doing of tedious, tiresome things there is little hope of a full measure of success.

With proper interest and incentive there is little need for much of the present skepticism regarding the possibility of making great strides toward disease reduction even among the class of patients that is encountered in dispensary practice. Nor is there such great reason to feel that dispensary treatment results cannot be made more nearly to approach those obtainable in private practice. One only has to study the results of Purcell and his co-workers<sup>1</sup> in the Salford Municipal Clinic to see that there is no real need for such a wide variation. As an exhibition of efficient dispensary teamwork I recommend the perusal of their report.

At no time has there been a greater general medical interest in gonorrhea than exists today. To a large extent the treatment atrocities that often did so much to promote the occurrence of complications have been eliminated from general usage. We need not here concern ourselves about just what particular plan of treatment should be used. Our chief concern is to find a way in which our dispensaries can be manned and properly equipped. We should realize that the day of long dispensary apprenticeships has passed and, deplore it as we may, men cannot and usually will not give the needed clinical service without some compensation.

1. Reported in the *British Journal of Venereal Diseases* 7: 151, 1931.

efforts. Every opportunity should be taken to convey to the people the facts as to plans and progress of the fight against syphilis. Conferences, lectures, motion pictures, press, the radio, exhibits, pamphlets and posters are useful and can be employed with satisfactory results provided reasonable skill and discrimination guide our efforts. Special attention should be given to the instruction of persons already infected; no educational work is more productive of good results. Instruction of doctors, nurses and social workers is of great importance. The department of health should take the initiative in providing postgraduate instruction for these groups in order that they may serve more satisfactorily in their respective spheres. Information regarding prophylaxis, chemical and mechanical, undoubtedly has a place in the educational program, but beyond that I am not prepared to go further than to suggest that physicians should be encouraged to administer prophylaxis and to advise regarding it. The fact that prophylaxis was an important element in the successful efforts of the United States Army and Navy to combat syphilis and gonorrhea leads me to believe that this subject should be investigated further with an open mind as to its place in a city program.

#### CASE FINDING

Case finding activities are of two general kinds: those associated with diagnosis and those associated with epidemiology. The health department should not only discover cases of syphilis and gonococcal infections through its own official services but should give every possible aid to physicians and institutions in case finding activities. These aids should include free, prompt and easily usable laboratory services, diagnostic consultation services and epidemiologic services. The service of the serologic laboratory of the city should be available free of charge to any doctor, hospital or clinic that cares to send a specimen of blood. The supply of containers and the collection of specimens should be convenient and the reporting of tests prompt. Furthermore, the health department should conduct diagnostic centers conveniently distributed throughout the city to which patients may be sent by physicians for darkfield, spinal fluid or other examination and for expert advice regarding diagnosis. Such centers should also receive for diagnosis all who come for advice or examination regardless of economic status, and these services should be advertised to the general public. In such diagnostic centers should be kept the names of physicians willing to accept patients who can pay a fee and such patients should be referred impartially to these private physicians. The department of health should promote and encourage diagnostic case finding procedures, such, for example, as routine blood tests in all hospitals, in all clinics, in private practice and in all sorts of groups where such procedures can be properly carried out. It goes without saying that every pregnant woman should be examined and tested for syphilis.

Epidemiologic case finding procedures, although the special duty of the health authority, should not be limited to health department services. Private physicians, hospitals and clinics should be encouraged to search out sources of infection and other contacts and bring them under appropriate control. But when a private physician, hospital or clinic requires the assistance of the health department in controlling sources of infection or contacts, the health authority must be ready in every such case to act promptly. In addition, the health authorities should be prepared to take the initia-

tive in certain cases. Thus where the health department operates clinics, the health authority must bear full responsibility for epidemiology. Also cases of early syphilis reported to the health department should at once raise the question as to the source of infection, and appropriate investigations should be made. In epidemiologic work, special attention should be given to early syphilis because the infection is recent, syphilis in pregnancy because the source of infection is often the husband, and congenital syphilis because the source of infection is the mother. With trained personnel, about 25 per cent of the source of infection of cases of early syphilis coming under clinic care can be found and brought under control.

#### TREATMENT

The solution of the problem of providing treatment for the many neglected cases of syphilis is not to be found in the establishment by the department of health of more and more and larger and larger health department clinics but rather in cooperation with private practitioners and voluntary hospitals and clinics. The department of health in its efforts to see that ample facilities for treatment exist should go as far as possible in aiding private physicians to care for patients having this disease. This aid should include (a) free drugs, regardless of the economic status of the patient, (b) free consultation regarding therapy and (c) the services of public health nurses in the follow up of lapsed cases and restoring them to treatment. Such aids result in many cases remaining under private medical care rather than adding to the burden of the taxpayers.

Clinics and the department of health itself should have lists of physicians who are willing to receive cases referred to them for treatment from the clinics to which they have come for advice. Local medical societies will provide such lists of physicians. Many physicians will accept cases of syphilis for very small fees if the drugs are supplied. But no infectious case of syphilis regardless of economic status should be refused treatment by the department of health.

The department of health should also aid approved voluntary hospital clinics in giving free care to patients. This may be done by providing drugs and follow up service for such clinics.

By aiding private physicians and voluntary hospital clinics to care for a larger number of patients, the department of health lightens its load, but, what is more important, it multiplies many times the facilities for treatment and makes these facilities available in every part of the city. Furthermore, such practical aids gain the cooperation of physicians and clinics in case finding and control activities.

When the facilities for treatment provided by private physicians and hospital clinics are not sufficient to meet the needs of a city (and that is the situation practically everywhere in this country at this time), the department of health must operate clinics. These clinics should maintain high medical standards and should be the centers for educational, advisory, diagnostic and epidemiologic work as well as for treatment. They should be carefully planned to meet the known needs for evening as well as day sessions, be conveniently located, and, of course, be absolutely free. The medical profession of the city should be consulted regarding the need for, the location of and services of health department clinics.

The city should provide ample hospital facilities for the care of all cases of syphilis and gonorrhea requiring

board, by resolution, created the Division of Venereal Diseases, and this medical officer was elected to the position of chief of the division, subject to approval of the surgeon general of the army.

The venereal disease control regulations were subsequently amended, and syphilis and gonorrhea were declared to be infectious, contagious or communicable in nature, and written report was required within forty-eight hours after diagnosis. Through a cooperative agreement with the state board of administration, camps for both men and women were developed at Lansing, where quarantine of infectious cases was not only instituted but also treatment given.

Thus the venereal disease control program developed in our state. In the summer of 1918 there was a general educational program conducted by the State Council of National Defense and the State Board of Health. Visits were made to all cities of more than five thousand population and governing bodies were requested to enact venereal disease control ordinances. As a result, with the exception of two cities, ordinances were adopted by the remaining cities of over ten thousand population.

The first venereal disease clinic was established at Rosedale on July 1, 1918, and the second four days later at Leavenworth. The state laboratory was established at Rosedale in November 1918, in cooperation with the University of Kansas School of Medicine, and serologic and bacteriologic examinations were made for syphilis and gonorrhea, without charge to the physicians.

The Kansas Medical Society at the annual meeting in May 1919 unanimously adopted a resolution endorsing the venereal disease control program, which at that time included (1) free laboratory examinations for syphilis and gonorrhea, (2) distribution of neoarsphenamine for the treatment of indigent cases of syphilis, and (3) distribution to physicians of a manual on the treatment of venereal disease.

In the meantime the validity of the venereal disease control program had been attacked. The Topeka police in a raid had apprehended a number of men and, on examination by the city health officer, several were found to be infected with gonorrhea. Orders were issued to the chief of police by the city health officer to transfer three of the men to "the state penitentiary at Lansing, Kansas, as the place and limit of the area" in which they were to be isolated. However, the infected men employed an attorney and original proceedings in habeas corpus were filed in district court. The writ was denied and then the case was carried to the supreme court of the state, which upheld the validity of the state regulations and city ordinance. The court did state that the term "state penitentiary" should be amended by employing the official designation, "The State Quarantine Camp for Men, at Lansing."

It is desired to refer briefly to one section of the supreme court decision, as follows: "The rules of the state board of health and the city ordinance are assailed as unreasonable. In this instance only those provisions of the rules of the state board of health and of the city ordinance are involved which relate to isolation of persons who have been examined and have been found to be diseased. Reasonableness of provisions relating to discovery and to examination of suspects need not be determined. It may be observed, however, that while provisions of the latter class cut deeply into private personal right, the subject is one respecting which a

mincing policy is not to be tolerated. It affects the public health so intimately and so insidiously that considerations of delicacy and privacy may not be permitted to thwart measures necessary to avert the public peril. Only those invasions of personal privacy are unlawful which are unreasonable, and reasonableness is always relative to gravity of the occasion. Opportunity for abuse of power is no greater than in other fields of governmental activity, and misconduct in the execution of official authority is not to be presumed."

During the life of the Chamberlain-Kahn act, it is believed that Kansas had a venereal disease control program comparable with those in other states, at least of corresponding population. Adequate treatment facilities were available to the indigent population through the services of practicing physicians and the operation of eleven clinics located in the larger cities. Not only was the program coordinated with medical services for the indigent but there was an excellent educational and enforcement program. There was unusual cooperation by the physicians in the reporting of cases.

In 1920, in addition to the director, a social investigator and educational director were employed. In the following year, owing to a reduction in the budget, all aid to clinics was discontinued except supplying free neoarsphenamine. Because of lack of funds to pay his salary, the director resigned effective July 1, 1923, and direction of the work was assumed by the secretary. One year later, and with a further reduction in the budget, it was necessary to dispense with the services of the educational director and the work was then limited to the work of the social investigator and the distribution of pamphlets and posters, slides, moving pictures and free neoarsphenamine. The investigator resigned in 1925.

In the course of time the moving picture films became worn and it was necessary to discard them. Distribution of pamphlets has been continued as the result of the cooperation of the United States Public Health Service in permitting the reprinting of these publications by the Kansas state printer. Distribution of free neoarsphenamine was also continued until 1933, through funds appropriated to the Public Health Laboratory.

Owing to a lack of funds and also the opposition to free treatment, the number of clinics gradually decreased. Since 1930, clinics have operated in only the three large cities; namely, Kansas City, Wichita and Topeka.

In 1927, in cooperation with the United States Public Health Service, a study of venereal disease prevalence was made in twenty-two Kansas counties. Information was requested only as to the total number of cases under treatment or observation on June 1 of that year. The population in the twenty-two counties totaled 617,972 persons. In all, 742 physicians were requested to cooperate. When the data were tabulated it was learned that only 42 per cent of physicians had cases under treatment and that 10 per cent did not treat syphilis or gonorrhea. In all, the 742 physicians reported 1,860 cases of gonorrhea and 1,275 cases of syphilis under observation or treatment on the specified day.

Further reductions were made in the state health department appropriations by the 1933 legislature. It was then necessary to limit the activities of the public health laboratory and at the annual meeting that year a regulation was adopted requiring applicants for a

progresses dangerously. Recently White<sup>5</sup> reported that, among 1,249 hypertensive cases, auricular fibrillation occurred in 171 (13.7 per cent), being paroxysmal in fifty-five.

The material in this study is based on the analysis of 158 cases of hypertensive heart disease with established

TABLE 2.—Percentage of Age Groups at Death

auricular fibrillation. This was 25.3 per cent of 623 cases of hypertensive heart disease previously studied.<sup>6</sup> Forty-four (23 per cent) of the 191 patients with hypertensive heart disease who died had auricular fibrillation. The incidence of this arrhythmia was approxi-

heart disease, since it occurred with equal frequency in all groups of living and deceased patients.

The time of onset of the fibrillation was obtained from the patients by careful questioning, as the arrhythmia was present in the majority of patients when each was first examined. It was not difficult to determine from the stories of these patients whether the auricular fibrillation preceded the onset of the symptoms and signs of congestive heart failure or whether it occurred after the congestive failure had been present for some time. The arrhythmia preceded the onset of the symptoms of cardiac failure in forty-four (27.8 per cent) of the 158 cases.

The patients in whom the arrhythmia appeared previous to the onset of cardiac symptoms came for treatment early, as none were seen later than four months after the appearance of the arrhythmia (table 3). In the remainder of the patients the auricular fibrillation occurred within one month to many years after the symptoms of cardiac failure were first noted. The course of the disease was not greatly influenced by the

mately the same in the deceased and in the living patients. There were 336 white males, of whom 106 (31.5 per cent) had auricular fibrillation, and of the ninety-nine who died twenty-eight (28.2 per cent) had the arrhythmia. There were ninety-four white females, of whom thirty-three (35.1 per cent) had auricular fibrillation, and of twenty-two who died, eight (36.1 per cent) had the irregularity. Of the total number of white patients with hypertensive heart disease 32.3 per cent had auricular fibrillation and of the total deceased white patients 32.2 per cent had the arrhythmia. In the colored patients the percentage of cases in each sex, although much less, indicated the same relationship. There were 144 colored males, of whom fifteen (10.4 per cent) had auricular fibrillation, and of fifty-three who died, six (11.3 per cent) had the arrhythmia. Of forty-nine colored females four (8.1 per cent) had auricular fibrillation and of seventeen who died two (11.8 per cent) had the irregularity. The incidence of auricular fibrillation in the total colored patients was 9.8 per cent and in the total deceased colored patients 11.4 per cent. These details indicate that auricular fibrillation was not a late manifestation of hypertensive

arrhythmia when it followed the appearance of the congestive failure. It supervened in 75.8 per cent of the cases within two years after the onset of cardiac manifestations, and in the remaining 24.2 per cent it appeared from three to ten years after the onset of symptoms.

There is a renewed interest in the problem of syphilis and gonorrhea, not only among professional groups but among lay groups.

Within the past month each of the two newspapers in Topeka printed articles in regard to venereal disease, as compared with the previous custom of referring to them as "social diseases."

It is hoped that additional treatment facilities may be provided through the development of full-time county or district health departments. There are certain areas in the state where it is considered that this would be especially advantageous.

There is nothing spectacular in the Kansas program. Allotment of funds by the Public Health Service has made the program possible. The Kansas State Board of Health and the physicians of Kansas wish to show their appreciation of this service by conducting an efficient, intelligent program to the end that syphilis and gonorrhea may be brought under control.

State House.

## THE NEW YORK STATE PROGRAM FOR SYPHILIS CONTROL

EDWARD S. GODFREY JR., M.D.  
ALBANY, N. Y.

The essential features of the New York State syphilis control program were described by Parran<sup>1</sup> in a paper published in *Venereal Disease Information* over a year ago. This paper called attention to an increased appropriation by the 1935 legislature for syphilis control and certain other services and outlined New York's district plan of health organization of which venereal disease activities were to be a part. The 1936 legislature further increased the department's appropriation and, in addition to state funds, federal grants under the Social Security Act became available. It is my privilege to review the development of the syphilis program made possible by these funds and to report on progress made since Parran's paper.

### CASE REPORTING

It was announced on Jan. 1, 1936, that reports of laboratory examinations for syphilis would no longer be accepted as case reports. Reasons for making this change included recognition of the fact that a positive laboratory report is not of itself a diagnosis in any disease, and a desire to build up accurate morbidity registers reasonably free from duplicates. It was found impossible to enforce the new card reporting requirement throughout the state strictly until the first of September. Since that date a card report has been obtained for each syphilis case whether coming to the knowledge of the health department as the result of a laboratory examination or from some other source.<sup>2</sup> During September, October and November, reports for 3,925 cases were received as compared with 5,760 so-called reports during the preceding three months, when laboratory reports were still accepted from certain localities.

Following the passage of appropriate legislation, syphilis cases in places of less than 50,000 population not served by full-time health officers and in state

institutions were made reportable directly to the district state health officer rather than to the local health officer. This change was made because of the lack of proper facilities for handling records and dealing with other aspects of syphilis control in most communities served by part-time local health officers, and to safeguard the confidential nature of such records.

The new method of transmitting reports has been in effect since June and has been well received by the medical profession. A syphilis register has been established in each of the seventeen district offices. These offices now receive copies of positive reports from laboratories serving their respective jurisdictions. Such reports are checked against the register for duplicates, and card reports are obtained for all new cases. Similar procedures are in force in areas served by full-time officers, so that the state is covered by the morbidity reporting system.

The report card used is simple and calls for a very limited amount of information needed to identify and locate the case. Reporting by initials and date of birth is allowed if the physician does not wish to reveal the patient's name. The physician is asked to distinguish between congenital and acquired syphilis and to state whether the case is early or late. Similar distinctions between congenital and acquired and early and late cases have been made in Massachusetts for several years, but in spite of their obvious public health importance most states, including New York, have not required that they be made in morbidity reports. From January through October, reports were received of 15,104 syphilis cases, of which 1,852, or 12 per cent, were early acquired cases.

### SERVICES TO PHYSICIANS

Efforts to control syphilis are perhaps more closely related to diagnosis and treatment than is true of any other communicable disease. It is also true that, unlike most sufferers from tuberculosis, the syphilis patient is not sent to an institution but remains under the care of his physician or is treated at a clinic. For these reasons, assisting the physician as much as possible in the diagnosis and treatment of his syphilis cases is of outstanding importance.

New York is fortunate in having an excellent laboratory system, developed over a long period of years and with laboratories fairly accessible to physicians throughout the state. Besides the state laboratory in Albany and its branch in New York City, there are seventy laboratories in the state approved by the state department of health for serologic and other examinations of specimens for syphilis. These laboratories are all supported wholly or partially from public funds and render service without charge. During 1935 they examined more than 700,000 specimens for the diagnosis of syphilis or control of its treatment.

Further assistance is given the physician by supplying him with drugs for the treatment of syphilis cases. Since Jan. 1, 1936, arsenic and bismuth preparations have been distributed free to physicians and clinics through already established laboratory supply stations. As has long been true of biologic products, the physician may obtain drugs for the treatment of syphilis from his nearest supply station without charge, without reference to the financial condition of the patient, and without being asked questions of any sort. Sufficient quantities of arsenic and bismuth preparations for

Read before the Conference on Venereal Disease Control Work, Washington, D. C., Dec. 28, 1936.

2. For experimental purposes the system of accepting laboratory reports is being continued in Rochester, N. Y.

mur was heard throughout the precordium. The thyroid was slightly palpable and the lower extremities showed pitting edema. The clinical impression at this time was obesity, cardiac hypertrophy, early congestive heart failure and hypertension.

A teleroentgenogram showed the left cardiac border enlarged to within 1 inch (2.5 cm.) of the lateral chest wall. The aorta showed moderate dilatation. An electrocardiogram (fig. 1) taken January 25 revealed an intraventricular block and alternation in form and amplitude of the QRS complex in derivations 1 and 3. Unfortunately an arteriogram was not recorded at this time to rule out pulsus alternans. An electrocardiogram taken two weeks later showed complete absence of electrical alternans, and the arteriogram at that time showed no pulsus alternans. The existence of isolated electrical alternans is not at all impossible in this case. The red blood count was 3,800,000, the white count 7,200, with 60 per cent polymorphonuclears, 38 per cent lymphocytes and 2 per cent monocytes. A voided urine specimen showed a specific gravity of 1.012, acid reaction, many granular casts and red corpuscles. Drugs given were digitalis and nitrites. Blood pressure February 17 was 185 systolic, 85 diastolic. The patient was advised to rest and follow a light diet. She was discharged the next day and has not been located since.

CASE 2.—Miss M. D., a white woman, aged 39, who was seen for the first time Jan. 12, 1931, had had rheumatic fever at the age of 12 years, which left her with a mitral stenosis and insufficiency and an aortic stenosis and insufficiency. Since that time she has had repeated attacks of heart failure. The family and personal histories were irrelevant. On auscultation the first heart sound was faint and was followed by a loud murmur heard at the base and apex. The aortic second sound was replaced by a blowing murmur, which was transmitted down the left sternal border. Fluoroscopic examination showed extension of the cardiac borders to the right and left. An electrocardiogram (fig. 2) taken January 13 showed myocardial damage and a left axis deviation. An arteriogram showed pulsus alternans. At that time the presence of a transient alternans of  $S_2$  was

Fig. 1 (case 1).—Record taken Jan. 25, 1935, shows electrical alternation involving  $R_1$  and  $S_2$ . The depressed  $ST_1$ , elevated  $ST_2$ , and the abnormally wide QRS, which is notched in all derivations, indicate the presence of intraventricular block.

not noticed but was later discovered when we were "alternans conscious." Treatment consisted of limited activity and digitalis.

The patient carried on for three years doing light work as a stenographer, but she was finally forced to give this up and go to bed, because of a decompensated heart. She was then in bed for two years, taking  $1\frac{1}{2}$  grains (0.1 Gm.) of digitalis daily. Sept. 1, 1936, the patient was visited at her home for further study. There was no change in her physical condition. A composite record (fig. 3) taken at this time showed no pulsus alternans. The electrocardiogram showed auricular fibrillation and slurring of  $R_2$  and  $S_2$ . In three separate portions of derivation 2 there was transient alternation of the R wave related to

inhalation.  $S_2$  showed alternation in amplitude for several successive cycles. A phonocardiogram showed no alternating phenomena. When last seen, September 1, the patient was bedridden and taking  $1\frac{1}{2}$  grains of digitalis daily.

#### LITERATURE

Green<sup>5</sup> produced ventricular alternation in the dog by periodically reducing the flow of blood to the region of the left ventricle supplied by the ramus descendens anterior. He found that "the region of impaired blood

Fig. 2 (case 2).—Record taken Jan. 13, 1931, shows transient alternation of  $S_2$  in conjunction with persistent pulsus alternans (brachial). The fourth and fifth waves of the arteriogram are about equal in amplitude, thus breaking at that point the exact alternation of the rhythm and ending the electrical alternans. The plus and minus signs denote the large and small waves respectively.

supply may merely contract less efficiently during the smaller beat or it may fail to contract at all; whereas in the larger beat it may contract normally or it may be depressed, but not to as great an extent as in the small beat." No electrical phenomena were reported in these experiments. Chini and Stefanutti,<sup>6</sup> Chini,<sup>7</sup> Condorelli<sup>8</sup> and Formenti<sup>9</sup> have also described the relationship between reduced myocardial nutrition and cardiac alternation. Carter and Faulkner<sup>10</sup> suspended terrapin hearts and by means of regularly spaced induction shocks showed distinct evidence of alternation in the transmission intervals of the ventricles which, according to them, depended on the degree of mechanical alternation.

Fischer,<sup>11</sup> describing a case of pulsus alternans in partial branch block, says that in the transition from a form of bundle branch block to a normal electrocardiogram the patient passed through a period of bundle branch block with a conduction relation of two to one (2:1); i. e., a regular alternation of a normal wave of left axis deviation with one of a following contraction of the type of right sided bundle branch block. A case similar to our first is reported by Castex and Ramirez.<sup>12</sup> There are several other foreign reports on electrical alternation.<sup>13</sup> There are few American publications on this subject.

of each early syphilis case in Buffalo, but only 17.5 per cent of such sources have actually been located and placed under treatment.

These Buffalo results have been cited not for the purpose of discouraging the investigation of early cases but to call attention to the magnitude of the problem and the necessity for a larger and better trained personnel before such investigations can be thoroughly carried out. Even though not complete in many instances, however, such investigations have been found to be a productive case finding procedure. Of the 237 contacts of early cases in Buffalo who were located and examined, 109, or 46 per cent, were found to have syphilis, and seventy-nine, or 33 per cent, of these individuals were suffering from the disease in an early infectious stage.

#### PUBLIC HEALTH EDUCATION

The theme of the department's lay educational activities during the past year and a half has been teaching the public that syphilis is a communicable disease, leaving the teaching of sex education to other agencies better equipped to handle it. Pamphlet distribution, exhibit material, lectures and methods similar to those employed in the past have been used. An increasing willingness on the part of the press to use the word "syphilis" and to discuss the disease frankly has been gratifying.

A series of institutes on syphilis control for laymen has been of special interest. Seven such meetings have been held during 1936 in large cities. Each institute has been sponsored by the local county medical society and by various lay organizations, such as the chamber of commerce and women's clubs. Invaluable service in organizing and carrying on institutes has been given by the State Committee on Tuberculosis and Public Health of the State Charities Aid Association. Luncheon, afternoon and evening sessions have been held at which the clinical and public health aspects of syphilis have been discussed together with the cost of the disease to the community. Out-of-state speakers have given addresses at several of the meetings. The response of the public to syphilis institutes has been surprising and entirely favorable. Audiences have been representative, large and interested. The institute method is believed to have been of great value as means for informing intelligent laymen as to what is being done, and particularly for stimulating interest in more adequate local appropriations for syphilis control.

#### CONCLUSION

In this progress report on the New York State syphilis control program, emphasis has been placed on notification and the provisions of adequate diagnostic and treatment facilities. Experience leads us to believe that these two phases of the program must be developed first, together with facilities for returning delinquent infectious cases to treatment. By assisting the localities where syphilis is most prevalent, namely, large cities, and by augmenting district staffs, it is hoped to raise the quality of treatment and to provide really adequate follow-up service. As time goes on it is believed that the problem will become less complex and that case and contact investigation can be more generally and effectively carried on. As has been said on other occasions, syphilis control presents a real challenge to physicians. It is for us to meet it.

State Department of Health.

## A TYPICAL CITY PROGRAM FOR COMBATING SYPHILIS AND GONORRHEA

CHARLES WALTER CLARKE, M.D.

Director, Bureau of Social Hygiene Department of Health  
NEW YORK

While the details of a modern program for combating syphilis and gonorrhea will differ from city to city in accordance with the size and character of the population of each, the principles involved in the program of each should be identical, since these principles are based on accepted scientific facts. Let us briefly examine these facts and the principles based on them:

1. It is possible to prevent infection with syphilis or gonorrhea by the avoidance of exposure to infection. Exposure being usually the result of voluntary action, it is believed that education which influences conduct has a place in the program.
2. It is possible by mechanical and chemical means to prevent syphilis and gonorrhea in spite of sexual intercourse with an infectious person. Therefore mechanical and chemical prophylaxis have a place in the program.
3. It is possible to break the chain of infection by rendering infectious individuals noninfectious by means of modern treatment. Therefore modern treatment has a place in the program of prevention.

Neither educational activities nor chemical or mechanical prophylaxis have so far succeeded in reducing radically the prevalence of syphilis or gonorrhea in civilian groups, and unfortunately gonorrhea cannot be rendered noninfectious quickly and permanently by the means of treatment now generally available. This is not to say, however, that education, prophylaxis and therapy may not under favorable future conditions be effective in reducing the prevalence of gonorrhea. Syphilis, on the other hand, can be rendered temporarily noninfectious usually with a few doses of arsphenamine, and by persistent treatment almost every patient becomes and remains noninfectious. Unlike gonorrhea, second infections with syphilis are so extremely rare as not to constitute a public health problem. If every patient with early syphilis received twenty doses of arsphenamine and forty doses of a bismuth or mercury compound properly administered, and if every syphilitic woman were treated adequately in every pregnancy, acquired and congenital syphilis would soon cease to exist. While greatest emphasis should be placed on early syphilis and on syphilis as a complication of pregnancy, almost every case of syphilis that has not been adequately treated should still be regarded as being potentially infectious.

With these principles in mind, the modern city program should be built up in three main divisions: (1) education, (2) case finding and (3) treatment.

#### EDUCATION

Educational activities are concerned, first, with the general public. They have for their objectives the rallying of public support for the city's fight against syphilis and the dissemination of knowledge of the nature, means of spread, necessity of treatment and methods of prevention of these diseases. When the people of the city understand the principal facts regarding syphilis and gonorrhea and the purpose and methods of the health department in combating these diseases, they will support the health officer in his

Read before the Conference on Venereal Disease Control Work, Washington, D. C., Dec. 28, 1936.

The presence of two successive pulse waves in figure 2 (case 2), each of low amplitude, may be due to the fact that the myocardial fibers did not recover sufficiently after one cycle to produce a wave of high amplitude. It is interesting to speculate whether this lack of recovery had anything to do with the cessation of the electrical alternans. Hamburger and his associates<sup>1</sup> explain that "the transitory nature of electrical alternans might be attributed to improvement of the heart, but it is just as likely, if not more likely, that its disappearance has exactly the opposite significance; namely, that the condition of the heart has become worse." That is, if the heart becomes better, all the waves are of the high amplitude type, whereas if it becomes worse all the waves are of the low amplitude type. One would expect to find, rarely indeed, a period of transition in which the large and small waves had a varying ratio to each other.

Lewis<sup>2</sup> says: "Curiously enough, the alternation in electrocardiogram and pulse is not always parallel; while a small R summit may correspond to the small pulse beat, yet quite frequently the large R corresponds to the small pulse beat." In figure 2 it is seen that a large S wave corresponds to a large pulse beat. According to Hamburger and his associates<sup>1</sup> "it is very easy to conceive of a distribution of alternating fractions in the heart such that the mechanical summation makes the alternans practically nonapparent with the methods available for recording mechanical events, while the electrical balance is favorable for a marked electrical alternans." These factors, they say, may be reversed, and one of our cases shows that they may exist together. These investigators also point out that the examiner should look not only for the presence or absence of pulsus alternans but also for alternation in the venous pulse, apex beat, heart sounds and electrocardiogram. We have been able to confirm their finding of the transitory nature of electrical alternans, which indicates the need for repeated tracings.

The records of Hamburger and his associates<sup>1</sup> show that some but not all inhalations cause transient electrical alternans of from one to three cycles. They attribute this to a probable pulmonocardiac reflex which impairs conduction of the impulse within the ventricles. Missal and Crain<sup>24</sup> state: "We could demonstrate no relationship between the appearance of electrical alternation and the respiratory cycle." Their patient had occasional convulsions and syncope. His electrocardiogram revealed alternation in the amplitude of T waves with changes in intraventricular conduction. The extremely active sinus carotid reflex in their case had no influence in the production of alternation. Case 2 (figure 3) of our report shows transient alternation in the height of R<sub>2</sub> related to inhalation.

#### SUMMARY

1. Electrical alternans consists of a regular alternation at equal intervals, in contour or amplitude, or both, of successive phases of the electrocardiographic record.
2. This phenomenon must be differentiated from pulsus bigeminus (coupling), pseudo-alternation due to respiration, and bidirectional complexes.
3. Electrical and pulsus alternans may occur separately or simultaneously.
4. The transitory nature of this phenomenon and its relation to inhalation as observed by previous investigators has been confirmed.

5. Cardiac alternation in whatever form it may appear, electrical or mechanical, has grave prognostic significance.

6. The ease with which electrical alternans may be overlooked and the transient nature of the finding indicate the need for repeated tracings and careful study of records, especially of patients suffering from myocardial damage.

604-605 Central Tower.

## Clinical Notes, Suggestions and New Instruments

### VISIBLE CONTACT TESTER

AARON BROWN, M.D., NEW YORK

With the separation of contact dermatitis from specific eczema (neurodermite), it has become increasingly more important to test properly substances that produce lesions on contact with the skin. In making contact tests, the substance is left in contact with the skin for a period of twenty-four hours or longer.

The simplest device used is a square of adhesive plaster holding the substance against the skin. Cellophane has also been used, held down to the skin by adhesive plaster or collodion.

Celluloid apparatus, consisting of a spoon and a shield. The curve conforms to the curve of the arm. There are four holes for aeration.

The device described here offers these advantages:

1. Visibility. The reaction, if any, is seen at all times. This is important, as it is desirable to limit the amount of reaction. The patient is instructed to remove the substance from the skin as soon as any reaction is seen.
2. Protection against irritation from clothes and against injury.
3. Aeration. It prevents maceration of skin from accumulated perspiration.
4. Utility. It is equally useful for liquids and for solid substances.
5. Added value for protection in Dick, Schick and tuberculin tests.

The apparatus, made of celluloid, consists of a spoon and a shield. It has a curve conforming with the curve of the arm and has four small holes for aeration. The spoon may be

<sup>24</sup> Missal, M. E., and Crain, R. B.: Alternation Phenomena in the Electrocardiogram, *Am. Heart J.* 11: 615 (May) 1936.

hospitalization in the interest of the patient or of the public health. These bed facilities should be of three kinds: (1) for the quarantine of recalcitrant infectious cases, (2) for infectious patients willing to enter hospitals as voluntary patients (and most patients are quite willing if the facilities are decent) and (3) for non-infectious patients requiring bed care purely on medical indications. Whenever an infectious patient cannot or will not protect his or her family and other near contacts from the risk of infection, that patient should be hospitalized. All patients with syphilis having infectious lesions should be hospitalized until temporarily noninfectious, after which ambulatory treatment suffices, if suitable follow up is provided to see that the patient does not lapse.

The laws of almost every state require physicians to report all cases of syphilis or gonorrhea coming under their care. Aside from purely statistical uses indicating especially the degree of cooperation given by the profession, reports of cases of syphilis and gonorrhea as of other communicable diseases should be used as a means of control and epidemiology. Thus, to illustrate, when a case of early syphilis is reported by a private physician, the department of health should cooperate with the physician in finding the source of infection. Again, evidence of a special outbreak of gonorrhea, as, for example, in a school, should lead to investigation. With skill and tact, much more can be done with these morbidity reports than merely to count and file them, a procedure that has led many doctors to remark "What's the use of reporting? Nothing ever happens." Reporting of syphilis and gonorrhea should be made convenient for physicians and free even of the expense of postage. It would be desirable to pay a small fee for each case reported. Obviously the confidential character of the reports must be absolutely protected.

## COMMENT

The foregoing principles and program include the full duty of the health authorities with regard to prostitutes, unless the state law or the sanitary code specifically lays additional responsibility on the health department, as is the case in New York. If a prostitute has infectious syphilis or gonorrhea, she is of concern to the health department. The fact that she is promiscuous makes her a more serious menace than the person who is not promiscuous. It helps in keeping our policies clear if we think of these individuals not as "prostitutes" but as infectious persons who are promiscuous and consequently highly dangerous. Such individuals should be kept safely under medical control as long as they are infectious, and this usually means quarantine in a hospital. Such a procedure is satisfactory in cases of syphilis, for infectious persons can be rendered permanently noninfectious. It is very unsatisfactory in cases of gonorrhea, because cure is uncertain and reinfections are common.

The necessary staff for carrying out the program for combating syphilis and gonorrhea in a city consists of an experienced and a well trained medical director assisted by physicians, nurses and clerical staff, and in larger cities by social workers, technicians, orderlies and statisticians. All members of the staff should be reasonably compensated. This, of course, includes the physicians working in the health department clinics. Voluntary service is usually unsatisfactory in one respect or another. The physicians and nurses should be specially trained or should at least be directed by specially trained supervisors.

The sources of funds for a city program are, first, the city budget; second, security act funds obtained through the state department of health, and, third, WPA funds obtained through special projects. The American Public Health Association once estimated that the program for combating syphilis and gonorrhea requires at least 11 cents per capita. This, I believe, is not sufficient if hospitalization is included, and hospitalization, I would repeat, is vital to a successful program. A nearer estimate to the cost of an adequate program, including hospital facilities, would be 25 cents yearly per capita of population.

The fact should not be overlooked that local voluntary agencies such as social hygiene societies can be of great practical assistance to us in many aspects of this program, especially with regard to popular education, professional training and the creation of favorable public opinion.

May I remark in closing that the program outlined is the one now in effect in New York City, and, while it is still in its developmental stages, we have gone far enough with each item to believe that the program is sound and practical.

## AURICULAR FIBRILLATION

ITS INFLUENCE ON THE COURSE OF HYPERTENSIVE  
HEART DISEASENATHAN FLAXMAN, M.D.  
CHICAGO

Various opinions exist regarding the incidence, the time of onset and the relation of auricular fibrillation to the course of hypertensive heart disease. Janeway<sup>1</sup> stated that of 212 deceased patients with hypertensive cardiovascular disease (nephritis included) only eight had auricular fibrillation, and of 246 living patients only two had this arrhythmia. White<sup>2</sup> reported that, in a group of 708 cases of hypertensive heart disease, auricular fibrillation was present in ninety-two (13 per cent), in fourteen of which it was paroxysmal in type. Under a discussion of the cardiac manifestations of essential

TABLE 1.—Percentage of the Age Groups at Onset

Ages	White				Colored			
	Male	Female	Total	%	Male	Female	Total	%

hypertension, Lewis<sup>3</sup> stated that established auricular fibrillation occurs in a number of cases but is observed particularly late in the disease. Fahr<sup>4</sup> differed with this opinion and stated that in some cases the onset of auricular fibrillation brings forth clinical evidence of heart failure. He added that it is the most common form of arrhythmia found associated with hypertension and that when it appears the heart fails rapidly and unless competent treatment is received congestive failure

From the Department of Medicine, Loyola University Medical School.

2. White, P. D.: *Heart Disease*, New York, Macmillan Company, 1934, p. 396.

3. Lewis, Thomas: *Diseases of the Heart*, New York, Macmillan Company, 1934, p. 232.

4. Fahr, G. E.: *The Heart in Hypertension*, *J. A. M. A.* 105:1396 (Nov. 2) 1935.

That this applies with equal cogency in the present instance is obvious enough when it is observed that:

- 1. No case histories are recorded.
- 2. No records of dosage or duration of treatment of individual patients are included.
- 3. No control series using other iodine compounds in equimolecular concentration are noted.
- 4. Only the number of patients, the total period of time that the physician himself has been using the preparation, and the physician's own personal opinion are given.

The ten letters of testimony were worded essentially and almost identically according to a form submitted by the manufacturer, which was worded as follows:

"I have prescribed Amend's Solution for approximately . . . patients over a period of . . . months.  
"During this period I have not seen a case of so-called iodism or gastro-intestinal upset caused from the use of this product.  
"I understand this statement is for submission to the Council on Pharmacy and Chemistry of the American Medical Association and permit its use for that purpose only.  
"Signed....."

Aside from the uncritical and fundamentally valueless nature of the evidence of therapeutic efficiency, the Council found the additional objection that it is a mixture of well known substances for which there appears to be no warrant.

The Council declared Amend's Solution not acceptable for New and Nonofficial Remedies because it is an unwarranted mixture marketed under false and misleading claims and intended to replace the use of well known, official preparations in similar disorders. The information as to the nature and amount of the "paranucleic acid" is inadequate, constituting a conflict with rule 1.

In reply to these criticisms of the Council, the firm stated that it was endeavoring to secure control tests but was unsuccessful in inducing physicians to prescribe their solution in doses equivalent to those which generally produce iodism when the official iodine solutions are used. In the absence of such comparative observations, however, any statements as to special freedom from iodism are meaningless or misleading.

Subsequently the firm did submit a report of a series of cases showing phenomena of iodism from the administration of Lugol's Solution which disappeared on substituting the Amend Solution; but the dosage of iodine in the latter was only a fraction of that in the Lugol's Solution. This series therefore does not demonstrate that the iodine in Amend's Solution is less liable to produce iodism than are the larger doses. As the administration of the Amend's Solution was preceded by larger doses of Lugol's Solution, this series gave no evidence as to the therapeutic efficiency, if any, of these doses of Amend's Solution. The Council therefore sees no reason to alter its conclusions and reaffirms its action declaring Amend's Solution not acceptable for New and Nonofficial Remedies.

TRICHOPHYTON EXTRACT POLYVALENT  
(DERMATOMYCOL)  
and  
TRICHOPHYTIN FILTRATE POLYVALENT  
(DERMATRICOFITIN)  
NOT ACCEPTABLE FOR N. N. R.

Trichophyton Extract Polyvalent (Dermatomycol) and Trichophytin Filtrate Polyvalent (Dermatricosfitin) were submitted for consideration of the Council by the Laboratorio Brasileiro de Chimioterapia, Ltda., Rio de Janeiro, Brazil. Although early information indicated that The Fellows Medical Mfg. Co., Inc., New York City, were exclusive distributors of these products in the United States, the present distributor, according to the Council's latest information, is Ernst Bischoff Co., Inc., of New York City.

Trichophyton Extract Polyvalent (Dermatomycol) is stated to be a vaccine of lysed germs prepared from mycelial growth of over 300 strains of pathogenic fungi—Achorion, Microsporum, Trichophyton, Epidermophyton and Endodermophyton—destroyed by acids, 0.4 per cent carboic acid being added as a preservative to the resulting liquid, which is filtered, neutralized, and sterilized at 100 C. It is not stated what these strains of pathogenic fungi are. It is well known that

there is more than one form of Achorion; that there are many types of Microsporum; many strains of Trichophyton; different strains of Epidermophyton—yet the expression is used: ". . . from the mycelial growth of over 300 strains of pathogenic fungi." This might be simply 300 strains of one particular organism of each of the five or of different cultures of the same organisms, i. e., taken from different sources, Trichophytin Filtrate Polyvalent (Dermatricosfitin) is stated to be a filtrate of the culture of over 300 strains of Achorion, Trichophyton, Microsporum, Endodermophyton and Epidermophyton, to which 0.25 per cent phenol has been added and the product sterilized at 100 C. It is intended exclusively for skin sensitivity tests in the diagnosis of dermatomycosis. The manufacturer states that these products are prepared under the license of O. da Fonseca, professor of parasitology of the Faculty of Medicine of Rio de Janeiro University, in charge of the Mycological and Parasitological Division of the Instituto Oswaldo Cruz of Rio de Janeiro, and E. A. Area Leao, chief of the Mycological Laboratory of the Instituto Oswaldo Cruz. A section of the material submitted by the firm is devoted to the treatment of dermatomycosis, quoting da Fonseca and Area Leao. Mention is made of vaccinotherapy of mycosis as carried out by former workers, and also of the work carried on at the Instituto Oswaldo Cruz at Rio de Janeiro. It is stated in the advertising that "the authors had the opportunity of treating or of being asked for advice or for the supply of the vaccine to several thousands of patients." A section is devoted to the prophylactic use of Dermatomycol. It is stated that da Fonseca and Area Leao have employed prophylactic vaccine treatment in a group of children in whom ringworm of the scalp occurs frequently, and that they were able to get rid of endemic cases by this means.

The Laboratorio Brasileiro de Chimioterapia, Ltda., states that it is impossible to give detailed statistical figures of the results obtained by vaccinotherapy of different types of dermatomycosis and keratomycosis, though this procedure has been used over a period of five years. The firm states, however, that a large number of complete records could be published. The preparation is claimed to have been of value in cases of uncertain or obscure etiology, and a few cases of psoriasis are stated to have been cured with Dermatomycol. A few pictures are submitted as proof. It is stated that Dermatomycol is indicated in the treatment of skin lesions produced by fungi, conferring on the organism gradual and specific immunity; favus, tinea favosa, tinea tonsurans of the scalp, microsporia, trichophytia, parasitic syphilis, kerion Celsi, onychomycosis, parasitic dyshidrosis, herpes circinatus, epidermophytia and Hebra's eczema marginatum are mentioned. A mixed treatment with the desensitizing agent and the vaccine is advised in "cases of long standing ringworm lesions with strong Dermatricosfitin reaction." Along with this some local treatment is advised, the use of Whitfield's ointment being recommended.

As to the clinical evidence presented, the referee of the Council noted a few case reports in the Portuguese literature submitted. These are all short, apparently not of a scientific type. The manufacturer states that comparatively little clinical evidence has been written concerning experiences with these products but assures the Council that the unwritten clinical history of Dermatomycol is impressive. The firm states that its use has been propagated among physicians by word of mouth, so that over 300,000 injections have been used; that the possibilities opened up through its use for treatment of many cases of psoriasis are extremely interesting.

Intradermal diagnostic tests with preparations of various mycelial growths have been used and recognized in dermatology for many years. The only difference between this new product and ones formerly used appears to be in its claim for multiplicity of organisms. The Council doubts whether this would make much difference either in the diagnostic value of the preparation or in the therapeutic value. It is well known that the therapeutic value of these products already on the market is quite limited; in fact it is seldom that with such a preparation alone a cure can be achieved, certainly not unless local agents are used as well. It is recalled that the Council has published a preliminary report on trichophyton extract, postponing further action to await the development of further clinical evidence from American dermatologists (THE JOURNAL, Nov. 19, 1932, p. 1779). The material offered as

arrhythmia precipitated the congestive heart failure, and this was the cause of death in all eight cases (table 4). The duration of the hypertensive heart disease in the known deceased, regardless as to whether the auricular fibrillation precipitated or followed the cardiac symptoms, was less than one year in 63.7 per cent of the white and in 87.5 per cent of the colored patients. Of the deceased white patients, 83.8 per cent succumbed within two years after the onset of the auricular fibrillation.

The occurrence of the arrhythmia during the course of hypertensive heart disease was unpredictable. It appeared previous to, during and after the onset of congestive heart failure. Only in the patients in whom the fibrillation preceded and precipitated the heart failure was the course of the disease shortened considerably.

There was a notable difference in the causes of death of those with auricular fibrillation as compared with all causes of death in hypertensive heart disease. Of the deceased white 83.3 per cent and of the deceased colored patients 87.5 per cent with this irregularity died of congestive heart failure (table 5). Twenty per cent more deaths occurred from this cause in the patients with auricular fibrillation than in those with regular cardiac rhythm.<sup>6</sup> Death due to the other common causes in hypertensive heart disease, such as coronary thrombosis, uremia and cerebral hemorrhage, was very infrequent in the patients with auricular fibrillation. The lack of additional occurrences also suggested an influence of the arrhythmia on the course of the disease. Coronary thrombosis occurred in only three (1.9 per cent) of the 158 patients with auricular fibrillation as compared with its occurrence in thirty-six (6 per cent) of the entire 623 patients with hypertensive heart disease.

TABLE 5.—Causes of Death

Totals.....	28	8	36	100.0	6	2	8	100.0

The occurrence of auricular fibrillation in patients with hypertensive heart disease influenced the course of the disease. The arrhythmia occurred with equal frequency in the same age groups in which the disease itself was most common. The ages at death were similar for those patients with regular rhythm and those with the arrhythmia. The frequency of the fibrillation was approximately the same in the patients who lived and in those who died. It precipitated congestive heart failure in 27.8 per cent of the patients in whom it appeared. The main cause of death in hypertensive heart disease, congestive heart failure, was more frequent in the patients with auricular fibrillation than in the entire group.

## SUMMARY

Auricular fibrillation, the most common form of arrhythmia in hypertensive heart disease, occurred in 158 (25.3 per cent) of 623 patients with this disease. It definitely influenced the course of the disease in

forty-four patients (27.8 per cent) in whom the rapid irregularity preceded and precipitated the congestive heart failure and led to an early death from this cause within one month after the onset in eight (18.1 per cent) of the forty-four patients. When the auricular fibrillation occurred after congestive heart failure had been present from one month to several years, it had no apparent influence on the course of the disease except in relation to the cause of death and the comparative absence of additional occurrences common to appear in hypertensive patients.

## ELECTRICAL ALTERNANS

## REPORT OF TWO ADDITIONAL CASES

JACOB G. BRODY, M.D.

AND

PHILLIP L. ROSSMAN, A.B.

YOUNGSTOWN, OHIO

Recently Hamburger, Katz and Saphir<sup>1</sup> described two cases of electrical alternans without pulsus alternans—the first reported in this country. This electrocardiographic phenomenon (fig. 1) has been exceedingly rare, but now that the Chicago investigators have made cardiologists "alternans conscious," to use their expression, we believe that relatively many more cases will be reported.

The two cases that are the subject of this report include one case of electrical alternans with demonstrable pulsus alternans and one case in which pulsus alternans was not demonstrated. Our first case was discovered Jan. 22, 1935. Careful search through our files then brought the additional case to light.

Electrical alternans consists of a regular alternation at equal intervals, in contour or amplitude, or both, of successive phases of the electrocardiographic record. White<sup>2</sup> says that electrical alternans accompanying pulsus alternans is rare; the QRS or T waves may rarely alternate in amplitude although not always in the same direction as in the arteriogram. Electrical alternans, like pulsus alternans (fig. 4A), is a sign of reduced myocardial reserve. It is of greater significance at slow or moderately increased heart rates than in extreme tachycardia.<sup>3</sup> It may vary in degree, it may be continuous or transient. Electrical alternans, like pulsus alternans, is also found following premature contractions in some cases.<sup>4</sup>

## REPORT OF CASES

CASE 1.—Mrs. M. B., a white woman, aged 65, a housewife, admitted to the hospital Jan. 22, 1935, complained of shortness of breath, swelling of the feet and palpitation. The past, personal and family histories were negative. The patient was in good health and quite active until December 1934, when an infection of the upper respiratory tract developed. Two weeks before entry the patient noticed shortness of breath on slight exertion. She coughed considerably, and one week later her legs began to swell. The patient was obese. On physical examination she was lying quietly in bed and was quite dyspneic. The temperature was 98.6 F., the pulse 70, the respiration rate 30 and the blood pressure 240 systolic, 130 diastolic. There was no dullness, and râles were absent. A loud systolic mur-

## SYPHILIS AND THE CENTRAL NERVOUS SYSTEM

The first suggestion that syphilis was etiologically related to dementia paralytica seems to have been based on the observation by Esmarch and Jessen of three cases of dementia paralytica in which there were lesions of tertiary syphilis. The fundamental contributions of Fournier and Erb forged the chain of evidence of the syphilitic origin of dementia paralytica and tabes. Other mile posts were the observations on congenital tabes and dementia paralytica, on conjugal association of these diseases with syphilitic lesions such as meningitis, similar conditions in the cerebrospinal fluid in cases of syphilis and of dementia paralytica or tabes, increased albumin and globulin reactions in both, the Wassermann reaction in the blood and in the spinal fluid, and lastly the finding of spirochetes in the central nervous system of patients suffering from dementia paralytica and tabes.

Neurosyphilis was considered late syphilis by the older authors. Strümpell believed it to be the result of the action of the syphilitic toxin on the central nervous system. The incubation period of dementia paralytica is from seven to ten years. Occasionally this period may be much shorter—two years or less. Nonne<sup>1</sup> states that syphilitic arteritis was present in one third of the early cases in his material and that cerebrospinal syphilis developed in about one half of them within the first three years. Acute syphilitic meningitis may be seen a few months after the infection. The contributions by the French school to the knowledge of the cerebrospinal fluid made possible the recognition of these acute early forms. The cerebrospinal fluid may show increase of cells and of globulin as early as the appearance of the initial exanthem or still earlier, at the time of the appearance of the primary lesion.

The question whether dementia paralytica and tabes are caused by the syphilitic toxin or by the direct action of spirochetes cannot be answered in the present state

of our knowledge. There is no constant or definite relationship between these neurosyphilitic manifestations and the presence, number and distribution of the spirochetes in the tissues of the central nervous system. Nonne emphatically rejects the idea of specifically neurotropic spirochetes. Patients who develop syphilis from the same source commonly develop different types of the disease. It is not unusual in conjugal syphilis to see one partner develop dementia paralytica and the other tabes, or one partner develop visceral syphilis and the other tabes. The question has been raised whether the antisyphilitic treatment itself was not a factor in the causation of these late complications. A number of investigators state that in countries in which syphilis was treated poorly or not at all, and in which secondary and tertiary manifestations were common, the occurrence of tabes and dementia paralytica was rare. These observations gave rise to the notion that mild syphilis predisposes to tabes and dementia paralytica. In an analysis of 1,270 cases of dementia paralytica and 1,372 cases of tabes seen in the course of fifty years, Nonne finds that in 80 per cent there were no secondary symptoms.

Attention has been called to the changing picture of syphilis in the last two decades, on the one hand a rapid diminution in the incidence of lesions of the skin and mucous membranes and in the frequency of ulcerative or gummatous lesions, and, on the other, an increase in the involvement of the blood vascular and the central nervous systems. Without in the least condemning the modern treatment of syphilis, the fact that it does not guarantee against dementia paralytica and tabes must be admitted on statistical evidence. Bruusgaard<sup>2</sup> reports the unique experience of the dermatologic clinic of the University of Oslo. Between 1891 and 1910, 2,181 patients suffering from primary or secondary syphilitic lesions were treated there on a hygienic constitutional regimen from which all available antisyphilitic remedies were excluded. Boeck, chief of the clinic, believed that the antisyphilitic remedies interfered with the regulating forces of the invaded organism and served to alter the course of the disease, thus leading to visceral and neurosyphilitic complications. The analysis of this material shows that neurosyphilis developed in only 3.4 per cent of the cases.

Early meningitic symptoms are not necessarily an indication of later dementia paralytica or tabes. Bruusgaard states that normal cerebrospinal fluid in the early stage of the disease does not guarantee against later dementia paralytica or tabes. Nonne found that patients who exhibited signs of meningitis did not, as a rule, develop either tabes or dementia paralytica.

Social status, alcoholism, trauma, cultural status and the constitutional type do not seem to play any part as predisposing etiologic factors. Nonne ventures the

## DIFFERENTIAL DIAGNOSIS

Electrical alternans might be confused with pulsus bigeminus (coupling)—seen often in overdigitalization<sup>14</sup>—in which a premature contraction occurs every second beat. In the latter condition, however, the interval between the normal beat and the premature beat is, of course, shorter than between the premature beat and the subsequent normal beat. In true electrical alternans the beats are equally spaced. Figure 4C shows a case of coupling in which the premature beats show alternation in amplitude. This is the only record of this type that we know of. The patient died of hypertensive heart disease one week after this record was taken.

The influence of respiration on the electrocardiogram must not be forgotten.<sup>15</sup> A rapid respiratory rate which equals one half the heart rate would produce a wave of high amplitude on exhalation and one of low amplitude on inhalation, which will at times simulate electrical alternans. Géraudel<sup>16</sup> shows such a record. The influence of respiration must also be considered in other types of alternans. Figure 4B is a composite record showing pseudo-alternation of the heart sounds. Every other beat occurs just at the beginning of inhalation.

Differentiation should also be made between electrical alternans and bidirectional complexes. Smith<sup>17</sup> presents a case of paroxysmal ventricular tachycardia displaying the latter phenomenon. White<sup>18</sup> shows a record of ventricular paroxysmal tachycardia with ventricular complexes alternating in direction and contour. He explains this alternation of direction of complexes on the basis of either two foci of origin or of two directions of spread of impulses from one site. The same explanation as is discussed later might be offered for electrical alternans.

Fig. 3 (case 2).—Record taken Sept. 1, 1936. The arteriogram, upper tracing, shows no pulsus alternans. The electrocardiogram, next lower, shows auricular fibrillation, slurring of  $R_2$  and  $S_2$  and left axis deviation. There was no alternation noted in derivation 1. Derivation 2 shows transient alternation of one to two cycles related, apparently, to inhalation. Derivation 3 shows transient alternation of the S wave. On the respiratory curve the descending portion corresponds to exhalation and the ascending portion to inhalation. The phonocardiogram, lower tracing, shows no alternating phenomena.

## COURSE AND PROGNOSIS

The serious prognosis of pulsus alternans at slow or normal heart rates is well known. Katz<sup>19</sup> says: "We feel that electrical alternans has the same significance, at a slow rate particularly, as pulsus alternans."

Thus according to Thomson and Levine,<sup>20</sup> in a series of seventy-one patients the average duration of life after the detection of pulsus alternans was fourteen and one-half months. Patients under 40 years of age average six months (five in this series) while those of 70 years or more average nineteen months of life. These authors

Fig. 4.—A, pulsus alternans in a case of rheumatic heart disease showing auricular fibrillation (derivation 3). Record taken Dec. 7, 1935. The plus and minus signs denote the large and small waves respectively. B, same case Aug. 18, 1936, under digitalis therapy. Derivation 3 of the electrocardiogram shows persistence of the auricular fibrillation. The arteriogram, upper tracing (inverted), shows no pulsus alternans. The phonocardiogram, lower tracing, reveals an alternation in the heart sounds which show systolic and diastolic murmurs. Sounds of smaller amplitude occur with each inhalation. The heart rate is double the respiratory rate. C, derivation 3 of a record of pulsus bigeminus in which the premature beats show alternation. The arteriogram, lower tracing, shows only one pulse wave to two heart beats because the premature beat occurs before there is any appreciable ventricular filling.

also showed that males with pulsus alternans lived twice as long as females and that the prognosis is worse when either systolic or diastolic blood pressure is elevated, when congestive failure is present, or when pulsus alternans occurs in the early hours or days following an acute myocardial infarction. In cases of intraventricular heart block the patients lived longer by more than 50 per cent than did those without it. However, there are exceptional cases of pulsus alternans in which the patients carry on quite satisfactorily for more than five years.<sup>21</sup>

## COMMENT

All types of alternans ("herzalternans" of Kish<sup>22</sup>), mechanical and electrical, are probably due to a state of the myocardium in which some fibers fail to contract with every heart beat, these fibers being refractory every other beat because of fatigue or insufficient nourishment. It may be, however, that electrical alternans is not due to fatigue or the exhaustion of energy-yielding material during the stronger beat but is due to either two alternating foci of impulse initiation or of two alternating paths of conduction from one focus. The latter two explanations would seem to be the case in phases which alternate in form especially, the former in phases which alternate in height. The refractory theory is supported by observations of Scherf and Zdansky<sup>23</sup> of a regular alternation in the size of the left cardiac border in a case of pulsus alternans (without electrical alternans).

A possible explanation for enamel disturbances in deciduous teeth from a clinical standpoint was suggested by Stein<sup>2</sup> as being incident to the shock of birth.

The work of Schour and his collaborators, carried on in the College of Dentistry of the University of Illinois, has shown repeatedly that the teeth are delicate and accurate recorders of metabolic disturbances. Indeed, in 1911 Erdheim<sup>3</sup> likened the dentin of the rat incisor to the drum of a kymograph, in which are recorded the disturbances in calcium metabolism in an accurate and easily readable manner. Schour<sup>4</sup> and his collaborators found deep-seated changes in the teeth following hypophysectomy, after single and multiple doses of parathyroid extract and following bilateral adrenalectomy. The work of Schour and his collaborators is interesting in recording group cooperation of investigators in medical schools with dental investigators. Some of this work was shown in the Scientific Exhibit at the Atlantic City session of the American Medical Association in 1935 and was awarded the certificate of merit in class I.

More recently, Schour<sup>5</sup> noted from a study of a number of decalcified and ground sections of human deciduous teeth selected at random the constant presence of a distinctive incremental line in the enamel and dentin at a position which corresponds to the surface of enamel and dentin that obtains at the time of birth. The incremental lines, commonly referred to as lines of Retzius in the enamel, to the uninitiated obviously appeared to be laid down with no defined pattern. Schour and his students<sup>6</sup> have found that these lines are laid down according to a well defined rate and in a well defined pattern. The fact that this distinctive line is of neonatal origin was established through an experimental study of the rate of growth of human enamel and dentin by means of small injections of sodium fluoride. Each injection of sodium fluoride produces a sharply accentuated incremental line in the enamel and dentin, forming at the time of injection.<sup>7</sup> The deciduous teeth in the experimental study showed a distinct line in the dentin that was formed some time before the injections were given. By measuring the distance between the last injection line and a hitherto unidenti-

fied line, it was ascertained that the unknown line must have appeared at the time of birth of the child. A corresponding line was found in the enamel and subsequently in other deciduous teeth studied. Of possible interest to clinical dentistry is the circumstance that prenatal calcification appeared to be better than the postnatal calcification.

The fact that these lines appear in the deciduous teeth and in some first permanent molars in which a cuspal portion is formed before birth and do not appear in the other permanent teeth or in the teeth of human full-term fetuses is of great significance in marking a definite division between prenatal and postnatal metabolism. It serves as a definite base line for speaking of prenatal and postnatal events, particularly those related to calcium metabolism.

The neonatal lines constitute a permanent biologic landmark which can be used to determine the amount and also the quality of the enamel and dentin laid down before and after birth. Their establishment paves the way for a number of investigations in the biology of the human teeth and of the new-born child. The further investigations that will flow from the appearance of such a fundamental phenomenon will be awaited with interest.

## Current Comment

### TETANUS

In a recent report Abel and his associates<sup>1</sup> record the latest results of their studies on the pathology of tetanus. They mention again the error that has been so influential in the development of a false pathogenesis of tetanus, and "scarcely less harmful as regards diphtheria and botulism." This was the belief that tetanus toxin was conveyed to the reactive cells of the central nervous system only by way of the motor fibers of peripheral nerves. The correction of this misconception and others related or subsequent to it has occupied the energies of these workers for a number of years.<sup>2</sup> Abel is particularly fitted by his long devotion and important contributions to the field of pharmacology to study the effects of poisons, whether chemical or biologic, and his experiments with tetanus toxin are a model for similar investigations in the future. This latest report deals with the quantitative aspects of tetanus toxin in blood and lymph of different animal species, and with their ability to bind and dispose of this toxin in such a manner that it is no longer recoverable from their organs. These workers find that the entire excess of toxin over and above one lethal dose accumulates in the blood and lymph, and a negligible quantity in the tissue spaces. Of this toxin about 90 per cent is recoverable from the blood-lymph system. However, the part of the toxin fixed by the cellular or other elements of the body cannot be recovered. This is par-

#### A NEW APPARATUS FOR PROCURING STERNAL BONE MARROW MATERIAL

R. B. H. GRADWOHL, M.D., St. Louis  
Director of Laboratories St. Louis County Hospital.

The first intravital examination of bone marrow was made by Wolff<sup>1</sup> in 1903. This was performed by trepanation of the diaphyses of the tibias of small animals. Human bone marrow of a living subject was first examined by Ghedini<sup>2</sup> in 1908. This method was used by Schilling and a number of other writers, including myself. I found it quite difficult to use this method on many patients for the reason that it entailed a surgical operation, and it was obviously impossible to repeat the puncture more than once or twice on the same patient. The difficulties incident to an operation of this type were removed by Arinkin<sup>3</sup> in 1929. He used a large needle and trocar and punctured the body of the sternum under aseptic conditions, using a local anesthetic.

The entire set-up for the procedure of procuring sternal bone marrow material: A, syringe; B, cannula and connector; C, bone marrow puncturing instrument; D, obturator.

Attention is called to the instrument<sup>4</sup> that I have devised and successfully used for this purpose. The accompanying illustration shows an entire set-up for the procedure. It consists of a 10 cc. Luer Lok syringe, a cannula and connector with a rubber tubing joint, a bone marrow puncturing instrument with a guard which can be adjusted to fit the depth of the sternal puncture and an obturator for the latter.

The skin over the sternomanubrial junction is surgically prepared, the usual sterile dressings are applied and local anesthesia with procaine hydrochloride solution is injected intradermally, subcutaneously and into the periosteum. The instrument for puncture has a handle which permits a firm grasp and allows one to bore through the external lamina of the sternum

and enter rapidly the marrow cavity of this bone. The instrument is thrust through the skin at the sternomanubrial junction at right angles to the surface of the sternum. The guard on the shaft of the needle is so adjusted that the instrument cannot possibly be pushed through the sternum into the mediastinal space. After the instrument has well penetrated the sternum, the direction is changed with the point directed upward. At this time, when the marrow has been entered, the obturator is removed, the connector and syringe are attached above the handle of the boring instrument and suction is applied. One obtains in this way a very definite specimen of the bone marrow. It goes without saying, of course, that the entire instrumentarium must be adequately sterilized before use. One may place a small amount of dilute sterile sodium citrate solution in the barrel of the syringe, which slightly dilutes the bone marrow material.

The large caliber of the instrument permits one easily to obtain sufficient bone marrow. Once the marrow is obtained, the instrument is rapidly removed and the opening closed with a surgical dressing. Repeated punctures on the same patient can be made with this instrument without any difficulty.

It is not necessary to remove a large quantity of bone marrow. Only a small amount is obtained, usually about from 0.2 to 0.3 cc.

Touch preparations are made on the surfaces of clean, fat-free glass slides. A few smears also are made.

The Giemsa is the best staining method. The specimens are dried in the air and fixed with methyl alcohol. The specimens are stained for thirty minutes with a dilute Giemsa stain made by taking a drop of stock Giemsa stain to each cubic centimeter of neutral distilled water.

After the staining process is completed the slide is washed with neutral distilled water, dried in the air and examined.

3514 Lucas Avenue.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.  
PAUL NICHOLAS LEECH, Secretary.

#### AMEND'S SOLUTION NOT ACCEPTABLE FOR N. N. R.

Amend's Solution was submitted for the Council's consideration by Amend Laboratories, Inc., as possessing "the therapeutic properties of any iodide or iodine preparation, with the added advantage of being non-toxic and non-irritating, and causing no disturbance whatever in the stomach or intestines, and producing not a single symptom of Iodism in any form."

At the same time the firm presented a solution for external use, Amend's External Iodine Solution, which, after extended consideration of the Council, was stated by the firm to be no longer marketed. The Council was referred to U. S. patent No. 1,841,694 for data concerning the formulas of these two products.

Amend's External Iodine Solution is stated to contain (as set forth in letters patent U. S. 1,841,694):

Iodine (crystalline) .....	12.7 Gm.
Irish moss .....	10.0 Gm.
Water, q. s. ....	ad 1,000.0 cc.

Amend's Solution is identical, with the exception that an unspecified portion of "paranuclenic" acid is added. In the patent it is stated that, for intramuscular or hypodermic medication, 0.3 per cent of sodium bicarbonate is added.

According to information in the Council's files, Amend's Solution is now being marketed by Thos. Leeming & Co., Inc., New York, as sole distributor.

As evidence for the usefulness of Amend's Solution, the firm presented ten testimonials from physicians, only one of which reports encountering any gastric irritation; none report iodism. As has been frequently pointed out by the Council, letters of testimony comprise the most uncritical of all methods by which to ascertain the therapeutic value of any drug or preparation.

2. Ghedini: Wien. klin. Wchnschr. 23: 1840, 1910.  
3. Arinkin: Folia haemat. 38: 233 (June) 1929.  
4. Made by the A. S. Aloe Company, St. Louis.

**Changes in Hartford Health Staff.**—Dr. Benjamin G. Horning has been appointed health officer of Hartford, according to the *New England Journal of Medicine*. Dr. Paul S. Phelps, Hartford, has been placed in charge of the bureau of tuberculosis. He is a graduate of McGill University Faculty of Medicine, Montreal, class of 1930. Dr. Horning graduated from Harvard University Medical School, Boston, in 1928.

**Bills Introduced.**—S. 423 and H. 637, to amend the chiropody practice act, propose to define "chiropody, or podiatry" as "the diagnosis of foot ailments and the practice of minor surgery upon the feet, limited to those structures of the foot superficial to the inner layer of the fascia of the foot; the dressing, padding and strapping of the feet; the making of . . . models of the feet and external medication limited to the feet." H. 1274 proposes to authorize the establishment and maintenance of a hospital for the care and treatment of persons suffering from infantile paralysis.

## DISTRICT OF COLUMBIA

**Society News.**—Dr. Thomas E. Mattingly addressed the Medical Society of the District of Columbia January 27 on contraception and Dr. Prentiss Willson, the rhythm of human fertility. At a meeting of the Washington Ophthalmological Society, January 4, ocular tuberculosis was discussed by Drs. Jonas S. Friedenwald, Baltimore, and Major James E. Ash, Army Medical Museum, among others.

**Medical Bills in Congress.**—*Changes in Status:* S. 989 has been reported to the House, proposing to issue a license to practice the healing art in the District of Columbia to Dr. Clarence Quinton Pair. H. R. 4536 has been reported to the House, directing the Board of Optometry of the District of Columbia to examine Welton B. Hutton for a license to practice optometry. *Bills Introduced:* H. R. 5142, introduced by Representative Barden, North Carolina, proposes to provide for the issuance of a license to practice the healing art in the District of Columbia to Dr. William Hollister.

**The Davidson Lecture.**—The Medical Society of the District of Columbia announces that the competition to select the winning candidate to deliver the Davidson Lecture, October 13, will close July 1. Physicians or other scientists working in the District are eligible to submit essays provided they have never been published. The essays must bear no indication of the author's identity, being signed by a nom de plume, with the identification in a sealed envelop bearing on its surface the same nom de plume. Dr. Coursen B. Conklin, 1718 M Street N.W., Washington, is the secretary of the Medical Society of the District of Columbia.

## GEORGIA

**Bills Introduced.**—H. Res. 105-470b proposes a resolution to request the board of regents and the chancellor of the medical college at Augusta, Ga., to establish a school of dentistry. H. 430 proposes to reduce to \$10, from \$15, the annual occupational tax collected from physicians, osteopaths, chiropractors, chiropodists, dentists and optometrists.

## IDAHO

**Bill Passed.**—S. 157 has passed the senate, proposing to repeal the present laws regulating the possession and distribution of narcotic drugs and to enact what apparently is presented as the uniform state narcotic drug act. The bill, however, departs from the uniform narcotic drug act in at least one important particular. It omits the provisions of the uniform narcotic drug act intended to limit the gross quantity of a habit forming drug a person can buy in exempt preparations within a forty-eight hour period.

**Bills Introduced.**—S. 109, to supplement the workmen's compensation act, proposes to make compensable "silicosis, monoxide gas poisoning, chronic lead poisoning, and such skin diseases which [sic] are traceable to the industry." S. 169 proposes to authorize boards of county commissioners to establish and maintain public general hospitals and "to fix reasonable charges for hospitalization, nursing, care, treatment, medicine, food and attendance, other than medical and surgical attendance . . . as the Board of Trustees shall deem reasonable," provided that the indigent sick or the otherwise dependent poor of the county shall be fully provided for without charge. In the management of such hospitals, no discrimination is to be made between licensed physicians and surgeons and "all such regular practitioners shall have equal privileges in treating patients in said hospitals." S. 172, to amend the laws relating to the practice of chiropractic, proposes (1) to authorize the commissioner of law enforcement to appoint a board of chiropractic examiners

to assist the department of law enforcement in examining and licensing applicants, in establishing rules and regulations with respect to acceptable preliminary education and accredited schools, and in conducting hearings on revocation or suspension procedures; (2) to provide that any licensed chiropractor may "adjust any displaced segment of the vertebral column or any displaced tissue of any kind or nature, for the purpose of removing occlusion of nerve stimulus in the bodies of human beings, and practice physiotherapy, electrotherapy, hydrotherapy, as taught in Chiropractic Schools and Colleges, but nothing herein contained shall allow any licentiate to prescribe medicine, perform surgical operations or practice obstetrics"; and (3) to make it a misdemeanor for a chiropractic licentiate to fail "to put after his name one of the following designations: Chiropractor, Doctor of Chiropractic, Philosopher of Chiropractic or Chiropractic Physician, on any sign, printed material, or other advertising."

## ILLINOIS

**Bill Introduced.**—H. 194 proposes to insert in the medical practice act the powers and duties of the department of registration and education with respect to the examining and licensing of applicants, the conduct of proceedings to suspend or revoke licenses, the formulation of necessary rules and regulations, and the appointment of committees to aid it in exercising these functions. These powers and duties are set forth at length at present in the civil administrative code but do not appear in the medical practice act proper.

**Society News.**—The Pike County Medical Society was addressed in Pittsfield, January 28, by Drs. Hermann Friedrich Engelbach, on "Pneumothorax in the Treatment of Tuberculosis"; George L. Drennan, "Otitis Media in Children," and Carl E. Black, "Preventive Surgery." All are from Jacksonville.—Dr. Lindon Seed, Chicago, will discuss "The Diagnosis and Determination of Operability of Toxic Goiter" before the Peoria City Medical Society, March 8. Dr. Howard A. Rusk, St. Louis, spoke on "The Irritable Colon" at the February 8 meeting, and Dr. Irving S. Cutter, dean, Northwestern University Medical School, Chicago, "The Future of Medicine," February 15.

**Free Drugs for Treatment of Rabies and Syphilis.**—A regulation adopted by the Illinois State Department of Health requires that dog bites and other injuries inflicted by animals on human beings be reported immediately. The regulation further requires that the circumstances surrounding each instance be investigated by the health officer or a physician designated by him to determine whether the animal concerned is rabid and whether the injured person needs antirabic treatment. Last year 5,336 persons were given antirabic treatment with vaccine supplied by the state department of public health. The heads of 877 dogs were examined in the laboratories of the department, and nine persons died of rabies in the state. The department also announces that drugs for the treatment of syphilis will be distributed free of charge in the future. Heretofore these drugs were available for indigent persons only. The change in policy was made to encourage early, adequate and efficient treatment by reducing the cost to the patient, regardless of his financial ability.

## Chicago

**Dr. Cutler Visiting Professor at Peiping.**—Dr. Max Cutler, director of the tumor clinic at Michael Reese Hospital, is spending two months at Peiping Union Medical College, Peiping, China, as visiting professor of surgery. Dr. Cutler will return May 10.

**Dr. Joslin Lectures on Protamine Insulin.**—Dr. Elliott P. Joslin, clinical professor of medicine, Harvard University Medical School, Boston, delivered the ninth annual Stephen Walter Ranson Lecture in Thorne Hall, Northwestern University, February 3, on protamine insulin.

**The Gehrman Lectures.**—Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., will deliver the Gehrman Lectures at the University of Illinois College of Medicine, March 22-24. His subjects will be "Health as a Factor in Social Security," "Industrial Hygiene," and "Syphilis." These lectures were scheduled for January 25-27 but were canceled on account of the flood emergency.

**Approval of Hospital Plan Withheld.**—The Chicago Medical Society is withholding approval of the group hospitalization branch of the Chicago Hospital Service Corporation until at least 51 per cent of the directors of the project are restricted to members of the society, according to the *Illinois Medical Journal*. The set-up of the plan now offers to physi-

evidence for the preparation under present consideration cannot be considered as adequate or convincing.

The Council declared Trichophyton Extract (Dermatomycol) and Trichophytin Filtrate (Dermotricofitin) unacceptable for inclusion in New and Nonofficial Remedies because they are preparations of indefinitely declared composition (Rule 1) and of unproved originality marketed under proprietary names (Rule 8) with unwarranted therapeutic claims (Rule 6).

When the foregoing report of the Council's consideration was sent the Laboratório Brasileiro de Chimioterapia, Ltda., the firm asked that the Council hold publication in abeyance while further investigation was being made. The firm indicated its willingness meanwhile to withhold active promotion of the product. Subsequently the firm of Ernst Bischoff & Co. took over the distribution of these products. That firm has recently informed the Council that it desires to proceed with the active marketing of Dermatomycol and Dermotricofitin at once. In view of this the Council was obliged to authorize publication of the report of its consideration of these products.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

### ACRIFLAVINE NEUTRAL-CALCO (See New and Nonofficial Remedies, 1936, p. 189).

The following dosage form has been accepted:

*Acriflavine Neutral-Calco, Vaginal Capsules, 1/2 grain:* Acriflavine neutral-Calco 1/2 grain (0.033 Gm.) in a one-half ounce soluble gelatin capsule containing an excipient the composition of which is sugar of milk, starch and talc.

**RINGER'S SOLUTION.**—Aqueous solution containing, in 1,000 cc., sodium chloride 7.0 Gm., potassium chloride 0.30 Gm., and calcium chloride 0.25 Gm.

**Actions and Uses.**—Ringer's Solution is used when chlorides and sodium, potassium and calcium have been diminished. It is indicated in all forms of dehydration but particularly in cases in which loss of gastro-intestinal secretions has resulted from vomiting, diarrheas or fistulas. It is also used in acidosis or alkalosis for improvement of circulation and stimulation of renal activity.

**Dosage.**—Ringer's Solution is given by all parenteral routes, chiefly subcutaneously and intraperitoneally.

*Ringer's Solution in Filtrair Container:* Each 100 cc. contains sodium chloride-U. S. P. 0.7 Gm., potassium chloride-U. S. P. 0.03 Gm., and calcium chloride (anhydrous) 0.025 Gm. Marketed in bottles (Filtrair containers) of 500 and 1,000 cc.

Prepared by Hospital Liquids, Inc., Chicago.

Ringer's solution occurs as a clear, colorless solution, possessing a slightly saline taste. The specific gravity is from 1.005 to 1.006 at 25 C. Twenty-five cc. of the solution concentrated to 10 cc. conforms to the U. S. P. XI test for heavy metals; 10 cc. of the solution conforms to the U. S. P. XI test for arsenic.

Concentrate 20 cc. of Ringer's solution to a volume of 5 cc., transfer to a test tube, add 1 cc. of freshly prepared sodium cobaltic nitrite solution, dilute to 10 cc., and mix thoroughly; prepare a standard solution of potassium chloride as follows: dissolve 1.5 Gm. of potassium chloride (dried at 200 C.) to make 1,000 cc. of solution. Transfer 4 cc. and 5 cc. portions of the standard potassium chloride solution to test tubes and add 1 cc. of freshly prepared sodium cobaltic nitrite solution. Dilute each portion of the standard to 10 cc., and mix thoroughly; the turbidity produced by the Ringer's solution at the end of ten minutes is less than that produced by 5 cc. and more than that produced by 4 cc. of the standard solution (limit of potassium [K<sup>+</sup>]).

Transfer 5 cc. of Ringer's solution to a Nessler tube, add 0.5 cc. of diluted acetic acid, 40 cc. of water, and 5 cc. of ammonium oxalate solution; dilute to 50 cc., and mix thoroughly; prepare a standard calcium acetate solution by dissolving 0.287 Gm. of precipitated calcium carbonate (dried at 200 C.) in 15 cc. of water containing 3 cc. of acetic acid and diluting to 250 cc. Transfer 1 cc. and 1.25 cc. portions of this standard solution to Nessler tubes, add 40 cc. of water and 5 cc. of ammonium oxalate solution and dilute to 50 cc.; the turbidity produced by 5 cc. of the Ringer's solution is less than that produced by 1.25 cc. and more than that produced by 1 cc. of the standard solution at the expiration of fifteen minutes (limit of calcium [Ca<sup>++</sup>]).

Transfer 25 cc. of Ringer's solution to a weighing dish, evaporate to dryness on the steam bath, place in oven at 150 C. for two hours, cool in a desiccator, and weigh; the weight of residue obtained is not less than 0.18 Gm. and not more than 0.19 Gm. Treat 25 cc. of Ringer's solution with an excess of sulfuric acid, evaporate to dryness, and ignite to constant weight at 750 C.; the weight of ash obtained is not less than 0.22 Gm. nor more than 0.23 Gm.

Transfer 10 cc. of Ringer's solution to a 400 cc. beaker, add 50 cc. of water and 4 cc. of diluted nitric acid; dilute to 200 cc., add 15 cc. of silver nitrate solution, heat to boiling and allow to stand until the precipitate is granular. Filter onto a weighed gooch crucible previously heated to 150 C.; wash the precipitate well with hot water; dry to constant weight at 140 to 150 C.; the chloride (Cl<sup>-</sup>) calculated from the silver chloride weight is not less than 0.0435 Gm. nor more than 0.0465 Gm.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

### HI-LO BRAND DOUBLE ACTING BAKING POWDER

**Manufacturer.**—Hi-Lo Baking Powder Company, Muskogee, Okla.

**Description.**—Baking powder consisting of cornstarch, sodium bicarbonate, sodium aluminum sulfate and calcium acid phosphate.

**Manufacture.**—The ingredients comply with definite specifications of purity, composition and granulation as analytically tested for conformity with specifications and food law requirements. They are weighed and thoroughly mixed in formula proportions. Each batch is tested for total carbon dioxide and proper mixture, then automatically packed in tins.

**Analysis** (submitted by manufacturer).—Total carbon dioxide (CO<sub>2</sub>) 15.7%, available carbon dioxide (CO<sub>2</sub>) 15.3%, residual (CO<sub>2</sub>) 0.4%, sodium oxide (Na<sub>2</sub>O) 14.1%, sodium as Na 5.6%, phosphorus pentoxide (P<sub>2</sub>O<sub>5</sub>) 6.7%, phosphorus as P 3.0%, aluminum oxide (Al<sub>2</sub>O<sub>3</sub>) 5.0%, aluminum as Al 2.7%, sulfur trioxide (SO<sub>3</sub>) 15.1%, sulfur as S 6.0%, starch 35.0%, combined water (by difference) 8.3%.

**Calories.**—1.4 per gram; 40 per ounce.

### SEXTON BRAND SWEET WRINKLED PEAS, WATER PACKED

**Manufacturer.**—John Sexton & Company, Chicago.

**Description.**—Canned peas, packed in water.

**Manufacture.**—Peas are harvested at the desired degree of maturity, vined, milled, washed, graded, inspected, blanched, again washed, and automatically filled into cans. The cans are filled with water, sealed and processed.

**Analysis** (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 87.6%, total solids 12.4%, ash 0.38%, fat (ether extract) 0.4%, protein (N × 6.25) 3.7%, crude fiber 1.18%, carbohydrates other than crude fiber (by difference) 6.7%.

**Calories.**—0.45 per gram; 13 per ounce.

**Claims of Manufacturer.**—Choice quality peas packed in water without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

### RED & WHITE BRAND FLOUR

**Distributor.**—Red & White Corporation, Chicago.

**Manufacturer.**—Blair Milling Company, Atchison, Kan.

**Description.**—A hard winter wheat "long patent" flour; bleached. The same as Blair's Certified Northern Type Flour (Bleached) (THE JOURNAL, Aug. 26, 1933, p. 675).

### MILTON QUALITY PINEAPPLE JUICE

**Distributor.**—M. I. Kimball Company, Lawrence, Mass.

**Packer.**—Hawaiian Pineapple Company, San Francisco.

**Description.**—Canned unsweetened pineapple juice, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p. 1769).

### ADVERTISING BOOKLET "BREAD WINNERS"

**Sponsor.**—General Mills, Inc., Minneapolis.

This is a leaflet prepared for distribution to the public. It is made up mainly of recipes and menus involving the use of bread.

necessary construction and alterations of the first and second floors of the northwestern wing of the hospital will be ready for installation of the machine June 1. Four patients can be treated at a time with the new machine, which will be used primarily for the treatment of deep-seated tumors. Drs. Edward Schons and John P. Medelman will be directors of the radiologic department of the hospital, which has a bed capacity of 199.

**Society News.**—The Cass County Medical Association was organized at a meeting in December in Walker. Dr. Otto F. Ringle, Walker, was chosen president, and Dr. Robert W. Campbell, Cass Lake, secretary.—Dr. Walter Schiller, Vienna, lectured at the Mayo Clinic, Rochester, January 22, on "New Findings in Ovarian Tumors." Dr. Cyril N. H. Long, professor of biochemistry, Yale University School of Medicine, gave a Mayo Foundation Lecture, January 28, on "The Physiology of the Adrenal Glands."—Dr. Evarts A. Graham, St. Louis, was the guest speaker at the fifteenth annual meeting of the Minneapolis Surgical Society, February 4; his subject was "Some Aspects of Disease of the Biliary Tract."—The Hennepin County Medical Society was addressed, January 27, by Drs. Charles W. Rucker and Kenneth A. Phelps on recent advances in ophthalmology and otolaryngology respectively.

### MISSOURI

**Bill Introduced.**—H. 276 proposes to repeal the present laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

**Spring Medico-Military Symposium.**—The spring medico-military symposium will be held in the auditorium of the Jackson County Medical Society, Kansas City, March 15-16. An address by Dr. Paul B. Magnuson, associate professor of surgery, Northwestern University Medical School, Chicago, will follow a symposium on the heart the morning of the first day; his subject will be "Differential Diagnosis of Pain in the Joints." The remainder of the two day program will be devoted to gastro-intestinal and respiratory symposiums and a session given over to the specialties. Luncheon addresses will be delivered by Major Gen. Stanley Ford, commander of the seventh corps area, Omaha, and Brig. Gen. Charles M. Bundel, commander, Fort Leavenworth, Kan. Evening sessions will be addressed by Drs. Magnuson on "The Immediate Diagnosis and Treatment of the So-Called Industrial Backache"; Peter T. Bohan, "Somatic Complaints in the Psychoses, Neuroses and Conflicts," and Claude S. Beck, associate professor of surgery, Western Reserve University School of Medicine, Cleveland, "Recent Advances in Cardiac Surgery."

### NEBRASKA

**Bill Introduced.**—Bill 270 proposes to require the state board of examiners in the basic sciences to keep a record of all their acts and proceedings, such record to include all questions, answers and grades in examinations given by the board. These records are to be public records available for public inspection. The examination papers, however, are to be kept for a period of only two years and are to be available for inspection only by the applicant or by the superintendent of his training school or other proper representative under regulations by the department of health.

### NEVADA

**Bill Introduced.**—A. 120, to amend the chiropody practice act, proposes, among other things, to make the terms "chiropody" and "podiatry" synonymous and to define chiropody or podiatry as "the diagnosis of foot ailments; the dressing, padding and strapping of the feet; the making of plaster models of the feet and the palliative, medical, surgical, manipulative, electrical and mechanical treatment of the functional disturbances of the feet, except amputation of the foot or toes, or the use of anesthetics other than local, or the use of drugs or medicine other than local antiseptics as taught and practiced in the schools of chiropody recognized by the board of examiners."

### NEW JERSEY

**Personal.**—Dr. Henry O. Carhart, Blairstown, has been appointed medical examiner for the state highway department, a newly created position.—Dr. George T. Tracy, Beverly, resigned the office of secretary of the Burlington County Medical Society after serving thirty-two years.

**Bills Introduced.**—S. 140 proposes to authorize courts to enjoin violations of the state sanitary code. A. 233 proposes to create a board of naturopathic physicians and to regulate the practice of naturopathy. The bill proposes to define the practice of naturopathy as "that system of the healing art which uses and prescribes the following practices and usages: diagnosis and the practice of the combined physiological, mechanical and material sciences of healing as taught in schools, institutes and colleges of naturopathy, which shall include physiotherapy, hydrotherapy, mechanotherapy, psychotherapy, phytotherapy, electrotherapeutics, corrective and orthopedic gymnastics, external applications, manipulation, and nutritional control." A. 235 proposes to enact a separate chiropractic practice act which would authorize the governor to appoint a board to examine and license persons to practice chiropractic. The bill proposes to define "chiropractic" as "the adjusting of the articulation of the vertebral column, and of the tissues adjacent thereto for the removal of nerve interference." A license to practice chiropractic, the bill proposes, "shall confer upon the licensee the right to diagnose and/or locate and remove interference to the transmission of nerve energy, according to the theory and practice of chiropractic, including the regulation of patient's diet, sanitary and hygienic habits; the use of the title, 'doctor' or 'Dr.' in connection with his name when accompanied by the name 'chiropractor' or 'philosopher of chiropractic' or 'Ph.C.' or 'master of chiropractic' or 'M.C.' or any such title tending to imply that he is a licensed chiropractor." A. 242 proposes to make it the duty of every physician, nurse, parent or guardian having charge of any child under 6 years of age who is totally deaf or whose hearing is impaired to report the facts in writing to the state department of health. The department is to investigate each case and if it finds that the minor is not receiving adequate care and treatment it must report the facts to the appropriate welfare or other official agency, which must provide for necessary care and treatment. A. 247 proposes to authorize the sexual sterilization of idiots, imbeciles, feeble-minded and epileptics. A. 255, to amend the uniform narcotic drug act, proposes to include the word "marihuana" in the definition of the word "cannabis," as used in the act. A. 260 proposes to make it mandatory for a person arrested for driving a motor vehicle allegedly under the influence of alcohol to submit to a physical examination by a physician as soon as possible after the arrest.

### NEW YORK

**Bills Introduced.**—A. 1167 proposes that "every city, town and village . . . shall be liable for, and shall assume the liability to the extent that it shall save harmless any physician rendering medical services of any kind gratuitously to a public institution, from damages for personal injuries alleged to have been sustained by reason of the malpractice of such physician while engaged in the rendition of such services." A. 1179 and S. 672, to amend the workmen's compensation law, propose to define "an occupational disease" as "a disease which is the natural and unavoidable result arising from conditions that are characteristic of and peculiar to, a particular trade, process, occupation or employment in which the employee was employed or engaged."

**Society Campaigns for Legible House Numbers.**—The Erie County Medical Society recently sponsored a campaign to have legible house numbers on all the houses in Buffalo in order that physicians might save time formerly lost hunting strange addresses. The society's committee on legislation placed the society on record as requesting that something be done about the thousands of houses without numbers and thousands of others with numbers that could not be read. With the aid of the newspapers, publicity was given to the plan and the city council passed an ordinance requiring owners of buildings to put on them in conspicuous places numbers 4 inches high and of a color in sharp contrast to the background. The penalty for violation of the ordinance is \$25. It is said that about 140,000 new house numbers were sold in Buffalo just before the ordinance went into effect. The Rensselaer County Medical Society has adopted a resolution asking a similar reform in the city of Troy, it is reported.

### New York City

**Art Exhibit Plans.**—The tenth annual exhibition of the New York Physicians' Art Club will be held at the New York Academy of Medicine, April 3-17. Original work in painting, etching, sculpture or arts and crafts by physicians is invited and must be delivered before March 13. For application blanks and full details apply to Dr. Louis C. Schroeder, secretary, 50 East Seventy-Second Street, New York.

theory that spirochetes may remain dormant in the organism of patients, both untreated and treated, and that these spirochetes may later become activated, invade the blood and cause lesions of the central nervous system.

### MIXED VACCINATION

Mixed or combined vaccination involves the simultaneous use of two or more vaccines or toxoids for protection of the organism against more than one disease. The first vaccines of this type consisted of typhoid and cholera bacilli, used experimentally in 1887 by Widal and Sicard and in 1902 by Castellani, who vaccinated human beings with typhoid and paratyphoid organisms. Since then combinations have been employed in the therapy of intestinal and wound infections, whooping cough, grip and other diseases. During the recent war the French used typhoid-paratyphoid A and B mixture and the Russians the tetravaccine typhoid-paratyphoid and *Vibrio cholerae*. The results of Friedberger, Imai, Mer, Weinberg, Davesne and Sanchez failed to confirm the value of the typhoid-cholera vaccine, although Widal and Sicard, Castellani, Bjeloussow, Predtetschenski and Wosskressenski, Weber, Zlatogoroff, Glusman and Kandyba<sup>1</sup> and Tanaka found an increase in antibodies against the individual microbes in the mixed vaccine. In 1926 Ramon and Zoeller<sup>2</sup> learned that when horses which were employed for diphtheria and tetanus antitoxin production developed abscesses at the point of inoculation the antitoxic titer of the blood serum became augmented. The injection of nonspecific substances such as tapioca powder, calcium chloride or dead microbes produced a similar stimulus. After inoculating one set of guinea-pigs with diphtheria anatoxin, a second with tetanus anatoxin and a third with a mixture of diphtheria anatoxin and tetanus anatoxin, they found that the third group possessed a higher antitoxic titer for diphtheria and tetanus than the other two inoculated with the single antigen vaccine. In similar manner Isabolinsky and Judenitsch injected animals with vaccine containing the typhoid bacillus and diphtheria anatoxin and found the agglutinin titer against the former as high as in the animals injected with the bacillus alone, and the resistance to diphtheria toxin as high as in the animals injected with the toxoid.

Hektoen and his students<sup>3</sup> have also shown that multiple antigens contained in a mixture do not impair or diminish antibody formation. Immunization of the rabbit with a mixture containing as many as thirty-two distinct and separate antigens resulted in precipitin

formation for each of the individual antigens, and the precipitins were removed from the immune serum successively by selective action of the individual antigen. Agglutinins and lysins as well for different species of blood corpuscles developed simultaneously in the blood of animals immunized with mixtures of ten kinds of laked blood.<sup>4</sup>

In man, Ramon and Zoeller, Zoeller, Martin, Loiseau and Laffaille, and Crouzou, Loiseau and Lafaille noted that the Schick test became negative in subjects inoculated with mixed vaccines one of the constituents of which was diphtheria toxoid. After having inoculated a French regiment with such a vaccine, Dopter<sup>5</sup> failed to observe superior results with diphtheria toxoid alone. Up to April 1933, of 18,126 French soldiers given the vaccine twenty developed diphtheria, while of 42,000 not so vaccinated 434 cases occurred. At present the military health service of France recommends the adoption of mixed vaccine prophylaxis. The combinations of vaccines employed are typhoid-paratyphoid-diphtheria toxoid, diphtheria toxoid-tetanus toxoid, diphtheria toxoid-scarlet fever toxoid, and typhoid-paratyphoid A and B—diphtheria toxoid-tetanus toxoid.

In view of the favorable regard toward the mixed vaccine abroad, confirmatory investigations would seem to be in order here. Certainly if a sound, durable immunity can be developed in this way (and this can be discerned by the Schick and Dick tests) the method will become important in prophylaxis for its convenience and economy.

### THE NEONATAL LINE IN HUMAN GROWTH

Certain periods in human growth and metabolism, such as the prenatal period, the neonatal period, the period of infancy, the period of puberty and the adult stage, bring with them deep-seated metabolic changes. Unfortunately there are few permanent biologic landmarks to separate these periods. Under ordinary conditions the new-born infant does not regain its birth weight until the end of the first ten days of extra-uterine life. It is not surprising that the severe metabolic disturbances which the new-born infant experiences during the time when it ceases its intra-uterine existence and has to adjust itself to the changes of extra-uterine life should leave their mark on the body. In 1933 Harris<sup>1</sup> found neonatal changes in bone; he points out that "in neonatal life, as a result of the catastrophic changes involved at birth, an arrest of growth concomitant with the loss of weight in the first week of life is of such frequency as to be almost a normal feature."

## PENNSYLVANIA

**State Tuberculosis Meeting.**—The annual meeting of the Pennsylvania Tuberculosis Society was held in Philadelphia, January 19-20. The speakers included Drs. Jay Arthur Myers, Minneapolis; Esmond R. Long, Philadelphia; Robert E. Plunkett, superintendent of tuberculosis hospitals, New York State Department of Health, Albany, and Kendall Emerson, New York, managing director of the National Tuberculosis Association. Dr. William Devitt, Allenwood, was reelected president.

**Bills Introduced.**—H. 859, to amend the medical practice act, proposes, in effect, to require applicants for licenses to practice medicine to be graduates of medical schools which require, as a condition precedent to admission, not less than two years or sixty semester hours of college credits, including one year in biology, one year in physics, one and one-half years in chemistry, including one-half year in organic chemistry, and six semester hours in English composition and literature. H. 907 proposes that no state-aided hospital shall be entitled to receive state appropriations if it requires any nurse or student nurse to work longer than eight hours in any twenty-four hour period, except as may be required to shift the hours of labor. H. 914 proposes to require the department of public instruction in issuing a renewal license to a practitioner of the healing art, or other person engaged in a trade or profession whose right to continue to so engage depends on the annual renewal of his license to practice, to collect from the licensee, in addition to the fee for the current year, the full amount of all fees and penalties for preceding years which the applicant for renewal has theretofore failed to pay. H. 915 proposes to authorize the department of public instruction "to fix the day in each year when the licenses or registration certificates for each profession or work at any trade or occupation for which annual renewals are required shall expire and on or before which renewals shall be secured."

## Philadelphia

**Medical College News.**—Mr. Joseph S. Conwell, Philadelphia attorney, has been elected president of Hahnemann Medical College and Hospital, succeeding the late Col. John Gribbel. —Mr. Robert P. Hooper was elected president of Jefferson Medical College recently.

**Personal.**—Dr. Harry A. Duncan was elected president of the Medical Alumni Association of the Medico-Chirurgical College of Philadelphia at its recent annual meeting. —Dr. Edward A. Schumann was elected president of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital at its fiftieth annual dinner in December. —Dr. Seth A. Brumm was honored by a stag dinner given by the Schuylkill County Medical Society December 8 in Pottsville, his former home.

**Professors Appointed.**—Dr. Francis Heed Adler has been appointed professor of ophthalmology at the University of Pennsylvania School of Medicine to succeed the late Dr. Thomas B. Holloway. Dr. Adler, 41 years old, has been visiting ophthalmologist to the Wills Eye Hospital. Dr. Francis C. Grant, assistant professor of neurologic surgery, has been appointed to a newly created professorship of neurosurgery in the school of medicine. Dr. Grant also holds a professorship of clinical neurosurgery in the Graduate School of Medicine of the university. Both physicians graduated from the school of medicine in 1919.

## SOUTH DAKOTA

**Bill Enacted.**—H. 75 has been approved by the governor, making it the duty of the governing agencies of the several public and parochial schools in the state to enforce the regulations of the state board of health requiring all teachers to obtain each year a certificate from a licensed physician showing the absence of active tuberculosis before they will be allowed to teach.

## TENNESSEE

**Bill Enacted.**—S. 174 has been enacted as Laws, 1936, c. 57, making it unlawful for any person, other than a registered pharmacist, wholesale druggist, producer or compounder, to sell, barter or possess cannabis or any compound, derivative or preparation thereof, except in accordance with the prescription of a licensed physician, dentist or veterinarian.

**Bills Introduced.**—H. 641 and S. 440 propose to require persons, associations or corporations manufacturing or selling products for which any vitamin claim is made to register the product quarterly with the commissioner of agriculture and at that time to pay a fee of \$50. It is to be unlawful to sell such products unless there is conspicuously printed on the container of the product the vitamin potency and U. S. P. XI units.

## TEXAS

**Bills Introduced.**—H. 555 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions. H. 851 proposes to prohibit the retail sale or other distribution of articles, drugs or medicinal preparations primarily manufactured, produced or intended for use as, or which may be used as contraceptives or prophylactics except by registered pharmacists or licensed physicians.

**Dallas Clinical Conference.**—The Ninth Annual Spring Clinical Conference of the Dallas Southern Clinical Society will be held at the Adolphus Hotel, March 15-18. Each morning there will be a general assembly, with lectures by guest speakers, followed by lecture courses given by local physicians. Luncheon periods will be devoted to round table conferences and afternoons to clinics in Dallas hospitals and at the hotel. The guest speakers and their subjects for the general assemblies are:

Chauncey D. Leake, Ph.D., San Francisco, Patent Medicine and Cosmetics.  
Dr. Charles F. McKhann, Boston, Poliomyelitis.  
Dr. Thomas G. Orr, Kansas City, Use and Abuse of Intravenous Therapy.  
Dr. Charles M. McKenna, Chicago, Treatment of Surgical Kidney with Special Reference to Kidney Stones.  
Dr. Elmer L. Sevinghaus, Madison, Wis., Irregular Menstruation and Fertility.  
Dr. William J. Dieckmann, Chicago, The Blood in Pregnancy.  
Dr. Walter I. Lillie, Philadelphia, The Inflamed Eye.  
Dr. William F. Rienhoff, Baltimore, Thyroid Disease.  
Dr. Joe V. Meigs, Boston, Ovarian Tumors.  
Dr. Francis E. Seneac, Chicago, Pruritus in Medicine.  
Dr. George E. Fahr, Minneapolis, Uremia and Pseudo-Uremia.  
Dr. William Mithoefer, Cincinnati, Nasal Catarrh.

Monday evening there will be a smoker with Dr. John Frederick Lubben Jr., Dallas, as master of ceremonies; Tuesday night a clinical pathological conference conducted by Dr. Henry M. Winans, Dallas. Wednesday night two symposiums will be presented: one on appendicitis by Drs. McKhann, Orr and Rienhoff; the other on kidney disease by Drs. Fahr, Lillie and Dieckmann. The annual clinic dinner will be on Thursday evening in the grand ballroom of the Adolphus. Dr. Winans is president and Dr. Everett C. Fox is secretary of the society.

## UTAH

**Bills Introduced.**—H. 183 proposes, as a condition precedent to the issuance of licenses to marry, that both parties to a proposed marriage present physicians' certificates that they are not infected with syphilis or gonorrhea. H. 192, to amend the law authorizing the sexual sterilization of certain socially inadequate inmates of state institutions, proposes that the control of sexual sterilization be vested in a board of five persons, one of whom must be a physician specializing in biology, one a physician in general practice, one a socially minded attorney, one psychologist and one psychiatrist. The bill further proposes that no sterilization operation shall be performed "unless the generative organs are found to be afflicted with incurable disease or diseases."

## VERMONT

**Bill Introduced.**—S. 38, to amend the workmen's compensation act, proposes that during the first fourteen days of disability the employer shall furnish to a workman injured in the course of his employment reasonable surgical and medical services and supplies not exceeding the amount of \$25 if the injured employee is not incapacitated for work for more than seven days, and, if the injured employee is incapacitated for work for more than seven days, then the employer shall furnish reasonable surgical and medical services and supplies during the first twenty-one days of disability but not to exceed \$50.

## VIRGINIA

**Medical College News.**—The cornerstone was recently laid for a new clinic and laboratory building at the Medical College of Virginia, Richmond. A new heating plant and a laundry have been completed at the college and a dormitory for the hospital house staff and the senior medical class is to be put in construction shortly. The building program of the college, amounting to more than \$1,000,000, has been financed by federal grants of about \$400,000, a gift to the school of \$300,000 and the sale of self-liquidating bonds of about \$300,000.

**Changes in State Health Staff.**—Dr. Charles Howe Eller, recently health officer of Charlottesville and secretary of the Albemarle County Board of Health, has been appointed director of the bureau of rural health in the state health department. He succeeds Dr. Edwin L. McQuade, who

ticularly true of the central nervous system and its branches, on which the toxin acts in a highly specific manner. The contention is that when toxin is recovered from various organs of the experimental animal it is only because of the "toxiferous" blood contained in these organs, and that carefully washed material is devoid of toxin, at least in a form recoverable by the methods used. This constitutes a departure from the currently accepted belief, but the departure seems well founded by the thoroughness with which the work has been done. The nature of this fixation of toxin presents a most important problem not only in tetanus but in kindred diseases. With it is bound up the entire question of antitoxin formation. It is to be hoped that continued investigation may shed some light on this problem also.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ALABAMA

**Society News.**—The Northwestern Division of the Medical Association of Alabama was addressed in Jasper, January 8, by Drs. Daniel C. Elkin, Atlanta, on "Diagnosis and Treatment of Wounds of the Heart"; Audiss M. Walker, Tuscaloosa, "Sinuses from Today's Aspect"; William W. Alexander, Florence, "The Postparalytic Management of Anterior Poliomyelitis"; Ollie P. Board, Birmingham, "Diagnosis and Treatment of Peripheral Vascular Disease," and Lewis C. Davis, Gordo, "Treatment of Lobar Pneumonia."

### ARIZONA

**Personal.**—Dr. Charles S. Smith, Nogales, has been appointed a member of the Arizona State Board of Medical Examiners, succeeding Dr. John E. Bacon, Miami, resigned. —Dr. Benjamin M. Berger, formerly city health officer of Phoenix, has been appointed superintendent of the state hospital for the insane at Phoenix, succeeding Dr. James R. Moore.

**Society News.**—Dr. Leon Unger, Chicago, addressed the Maricopa County Medical Society in Phoenix, December 21, on allergy. Dr. Bransford Lewis, St. Louis, addressed the society December 7 on "Nephropexy," and Dr. Ralph F. Palmer, Phoenix, on "Injection Treatment of Hernia." —Dr. Jesse D. Hamer, Phoenix, president of the Arizona State Medical Association, addressed the Santa Cruz County Medical Society at its annual meeting December 5.

**Bills Introduced.**—H. 150, to amend those provisions of the medical practice act relating to the practice of osteopathy, proposes (1) in effect to permit licensed osteopaths to practice medicine and surgery without restriction, (2) to require applicants for licenses to practice osteopathy, among other things, to file a diploma from a legally chartered school of osteopathy, the requirements of which shall have been at the time of granting such diploma not less than those prescribed by the American Association of Osteopathic Colleges for that year, and (3) to permit the licensing of osteopaths by reciprocity. H. 163 proposes to authorize the compulsory treatment of inmates of state institutions afflicted with contagious or infectious venereal disease and to permit the detention of such inmates beyond the periods of their sentences until such time as their discharge will not endanger public health.

### ARKANSAS

**Changes in Health Staff.**—Dr. Walter Myers Smith, Morrilton, has resigned as director of the field experience center to accept a similar position with the division of maternal and child welfare of the state board of health. Dr. William P. Scarlett, Morrilton, director of the Conway County health unit, will succeed Dr. Smith, and Dr. Scarlett will be succeeded by Dr. John M. Smith, formerly of Russellville.

**Bills Introduced.**—S. 297, to amend the chiropractic practice act, proposes (1) to require chiropractors to pay annual renewal fees of \$7.50 and (2) to make the annual renewal of a license to practice chiropractic contingent on the licensee's presenting evidence that he has "in the year preceding the application for renewal attended the annual educational program as conducted by the Arkansas State Association of Doctors of Chiropractic." H. 423 proposes to prohibit the retail sale and other distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of conception and/or venereal diseases except by licensed physicians and by licentiates of the state board of health. H. 452, to amend the chiropractic practice act, proposes to permit licensed chiropractors "to practice chiropractic in all its branches as taught and practiced in legally incorporated colleges of chiropractic." The bill defines legally incorporated colleges of chiropractic as "those that teach not less than a total of five thousand class hours in the following subjects: anatomy, physiology, chemistry, bacteriology, pathology, symptomatology, hygiene, chiropractic principles, diagnosis, minor surgery, obstetrics, gynecology, chiropractic adjusting and X-Ray operation." Under the present law chiropractors may adjust by hand the displaced segments of the vertebral column and any displaced tissue in any manner related thereto for the purpose of removing any injury, deformity or abnormality of human beings.

### CALIFORNIA

**Dr. Abbott Lectures.**—Dr. Maude E. S. Abbott, Montreal, Canada, lectured in Pasadena, December 3, at the Stanley Black Memorial Hall, on "The Influence of Sir William Osler, A Personal Reminiscence." Under the auspices of the Los Angeles Heart Association, Dr. Abbott also conducted clinics on congenital heart diseases at the Los Angeles Hospital, December 2, and at the Children's Hospital, December 3.

**Secretaries' Conference.**—The annual conference of county secretaries of the California Medical Association was held at the Sir Francis Drake Hotel, San Francisco, February 6. Drs. Edward M. Pallette, Los Angeles, and Howard Morrow, San Francisco, president and president-elect, respectively, and Morton R. Gibbons, San Francisco, chairman of the council of the state association, spoke. Other speakers included:

Dr. Thomas Henshaw Kelly, San Francisco, Hospital and Health Insurance.  
Dr. Rosco G. Leland, Director, Bureau of Medical Economics, American Medical Association, Chicago, Medical Economics.  
Dr. Charles A. Dukes, Oakland, Public Health Institutes.  
Dr. William W. Roblee, Riverside, Disciplinary Procedure.  
Hattley F. Peart, San Francisco, legal counsel for the state association, Malpractice Suits.  
Dr. Junius B. Harris, Sacramento, Legislation.  
Dr. Arthur E. Varden, San Bernardino, County Society Programs.  
Dr. Clarence G. Toland, Los Angeles, Postgraduate Programs.

### COLORADO

**Bills Introduced.**—S. 553 proposes to deprive the board of medical examiners, the board of chiropractic examiners, and all other healing arts licensing boards that may be created in the future, of the right to revoke or suspend licenses they have issued and to vest in appropriate district courts the right to revoke and suspend licenses. A district court may act in the matter, however, only on the complaint of a licensing board. Each member of a licensing board must file a surety bond in the sum of \$5,000 and failure to furnish such a bond is to terminate automatically the tenure of office of any member who is in default. Members of the board filing the complaint with the district court are to be personally liable to the licensee on their bonds for any damage to his reputation or business if he is acquitted of the charge against him and it appears that such charge was preferred falsely and maliciously. S. 613 proposes so to amend the law regulating the sale of hypnotic drugs as to include within its provisions "bromides or any compounds or mixtures thereof possessing hypnotic properties or effects."

### CONNECTICUT

**Society News.**—Dr. William T. Salter, assistant professor of medicine, Harvard University Medical School, Boston, addressed the Yale Medical Society, New Haven, January 13, on thyroid hormone. At a meeting of the society, February 10, Dr. Edwin F. Gildea, Evelyn B. Man, Ph.D., and Dr. John P. Peters, among others, discussed "Serum Lipoids in Hyperthyroidism."

**Physician Honored.**—Dr. Max Mailhouse, clinical professor of neurology, emeritus, Yale University Medical School, New Haven, was guest of honor at a dinner, February 5, in celebration of his eightieth birthday. Dr. George Blumer acted as toastmaster. Dr. Mailhouse graduated from Yale in 1878 and resigned from its faculty in 1920, after twenty years' service.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Feb. 6, 1937.

#### Protamine Insulin

At the Royal Society of Medicine, Dr. H. C. Hagedorn of Copenhagen described protamine insulin, which he has introduced. Oscillations of the blood sugar in severe cases of diabetes could be modified by appropriate distribution of the diet or by better timing of the insulin effect through modification of the insulin preparations. The latter method had been thought of as early as 1923 and his institute had taken much interest in it ever since. Three ways of retarding the effect of insulin had been tried: (1) emulsification of insulin solution or suspension of dry insulin in oil; (2) injection of a vasoconstrictor with insulin; (3) injection of insulin as a more or less insoluble compound. Theoretically, injection of a suspension of an insoluble compound gave a constant rate of absorption. He had restricted his experiments to substances which were destroyed or excreted rapidly, fearing that others would sooner or later cause some unpleasant surprises. Many protamines had been tried, and salmadin (obtained from the rainbow trout) had been chosen.

The clinical results were most encouraging. Both children and adults who used to have several periods in the hospital each year, being brought in in a hypoglycemic or semicomatose state, came no longer. There was one admission due to hypoglycemia from taking a big overdose of protamine insulin while in a condition of alcoholic intoxication. The prolonged administration of protamine insulin had prevented severe hypoglycemic attacks and also the rise of the blood sugar in the early morning. It enabled him to give only two doses a day to patients who, in spite of much juggling with food, required three or four doses of insulin hydrochloride a day. Single doses of protamine insulin given on waking had kept the blood sugar level to between 0.08 and 0.15 per cent for twenty-four hours. Naturally the distribution of carbohydrate had to be adjusted: 35 per cent at breakfast, two hours after injection, and 50, 10 and 5 per cent at lunch, tea and the evening meal. The total carbohydrate was often well over 200 Gm. But in some cases hypoglycemia developed about 11 a. m. and in others insulin was ineffective. The variable action probably depended partly on the site of the injection.

#### The Wellcome Trust

The late Sir Henry Wellcome, the sole proprietor of the firm of Burroughs, Wellcome & Co., made magnificent gifts to medical science during his life. His will provides that his whole estate, after providing for certain charges, will be devoted to this purpose. His instructions are as follows: 1. For the maintenance of the Research Undertaking Charity, which is a fund for the advancement of medical and scientific research work in any part of the world conducive to the improvement of the physical conditions of mankind, and in particular for the discovery, invention and improvement of medicinal agents and methods for the prevention and cure of disorders, and the control or extermination of insects and other pests that afflict human beings and animal and plant life, and also for the organization, equipment and expense of special research expeditions and commissions. 2. For the maintenance of the Museum and Library Charity, which is a fund for the establishment or endowment of research museums or libraries in any part of the world for the collection of information of every kind connected with the history of medicine, surgery, chemistry, bacteriology, pharmacy and allied sciences which in the opinion of the trustees may be desirable. Three of the trustees must

be business men and two men of medical eminence. Sir Henry Dale, F.R.S., director of the National Institute of Medical Research, and Prof. T. R. Elliott, F.R.S., director of the Medical Unit, University College Hospital, are appointed. In a letter to the press the trustees state that they believe that this is the first example, in this country at least, of a testamentary decision by which the whole of the profits of a great manufacturing and trading organization, after certain personal and memorial bequests have been fulfilled, are permanently dedicated to the advancement of knowledge for the general benefit of mankind.

#### The Migration of Women in the British Empire

In a debate in the House of Commons on the empire settlement bill, more than one member drew attention to the need to encourage British women to migrate to the dominions. It was pointed out that, while in Great Britain the women outnumber the men by 1,000,000, in every dominion the men outnumber the women. Owing to industrial depression in the dominions and to antagonism to immigration of the labor parties there, this process has been almost at a standstill for some years. Nevertheless the Society for the Overseas Settlement of British Women has been able to show gratifying results. The total last year was 476 against 365 in the previous year. The number of professional women settled was 333, against 228, 187, 140, 152, 204, 262 and 254 in the preceding years backward. Of the emigrants last year 294 went to the Union of South Africa, eighty-five to Rhodesia, forty-six to Australia, twenty-two to Kenya, sixteen to Canada and four to New Zealand. The society reports an increased interest in migration to the dominions on the part of well qualified women with an urge for adventure. It prefers women between 25 and 35, and single for choice. The posts which the society fills include those of schoolmistresses, nursery governesses and children's and hospital nurses. During 1936, 116 hospital nurses were settled in South Africa and Australia, compared with fifty-eight in 1935. The society gives advice to women desiring to join friends or relations overseas as well as those who desire to obtain employment. It suggests that some form of assisted emigration would greatly help to people the British Empire with the right sort of British women. Not every young woman, however enthusiastic she may be, can find the \$200 to take her to Australia or the \$125 to reach South Africa.

#### High Voltage Roentgen Therapy

At St. Bartholomew's Hospital a new high voltage roentgen therapy department, the gift of Mrs. Meyer Sason, designed to give a beam of greater penetrative power, higher intensity and shorter wavelength than any heretofore used in the treatment of cancer, has been inaugurated. The x-ray tube is 30 feet long and weighs 10 tons. The treatment room is flanked by two generator rooms, and the tube runs from one generator room to the other across the treatment room. The portion within the treatment room is surrounded by a protective sheath, consisting of a 6 inch layer of lead shot between steel cylinders. The beam is transmitted through an aperture in this sheath. As the tube is fixed, the floor of the treatment room is movable, so that the position of the patient with regard to the tube can be adjusted. Two generators, each of 600,000 volts, one of positive, the other of negative, potential are provided. The current for each generator is fed from the 400 volt alternating current mains into a transformer. By means of a special circuit embodying columns of continuously evacuated thermionic valves and oil immersed conductors, a rectified current at a constant potential of 600,000 volts may be obtained, and thus by using both generators a constant potential of more than a million volts can be applied to the tube. A protective wall of barium concrete has been built between the source of radiation and the operators.

cians the representation of seven directors out of fifteen, of which three may be nominated by the affiliated hospitals and two to represent the administration. Two may be nominated by the Chicago Medical Society.

### INDIANA

**Bill Passed.**—S. 203 has passed the House, proposing to amend the workmen's compensation act, by extending the period following an industrial injury during which an employer will be required to furnish medical and hospital aid to an injured workman, to ninety days. The present law imposes this liability only during the first thirty days after an injury.

**Society News.**—Drs. David L. Smith and Carl Habich discussed "Episiotomy and Perineal Repair, Indications and Technic" and "Trichomonas Vaginalis Vaginitis" before the Indianapolis Medical Society, January 19. At the meeting, January 26, Drs. Murray N. Hadley and Charles A. Weller lectured on "Indications for Gastric Decompression" and "Peptic Ulcers and Their Relation to Trauma" respectively. Dr. Kenneth G. Kohlstaedt addressed the society January 12 on "The Hippuric Acid Excretion and Urea Clearance as a Test of Hepatic Function," and Dr. Frederic W. Taylor, "Early Operation in Acute Gallbladder Disease."

**State Projects Plan for Crippled Children.**—A survey is now under way in Indiana to complete a register of all crippled children in the state, according to the *Journal of the Indiana State Medical Association*. With the approval of the Indiana plan for services to crippled children by the Children's Bureau, U. S. Department of Labor, January 12, the state is now participating in all phases of the Social Security Act. The James Whitcomb Riley Hospital, Indianapolis, has been selected for the admission of nonindigent cases of spastic paralysis. South Bend and Evansville have also been designated as hospital centers in the program, but the names of cooperating hospitals have not yet been announced. A general advisory committee has been appointed by the Indiana State Board of Public Welfare to correlate the activities of various public and private agencies interested in the project.

### IOWA

**Refresher Courses.**—The speakers' bureau of the Iowa State Medical Society is presenting six "refresher" courses in two circuits of three centers each. There will be eight two hour lectures, four on pediatrics and four on obstetrics. The fee will be \$1 to cover the cost of mimeographing the lectures. The east circuit comprises Osceola, Centerville and Keokuk, where the lectures are being given Tuesdays, Wednesdays and Thursdays respectively. The course for the west circuit, comprising Panora, Denison and Red Oak, will begin March 9, with the lectures on Tuesdays, Wednesdays and Thursdays, respectively. The courses are under the auspices of the University of Iowa College of Medicine, the Iowa Pediatric Club, the Central Association of Obstetricians and Gynecologists and the state department of health. The bureau will also conduct three of its regular extension courses in general therapeutics in Ames, Fort Dodge and Mason City.

**Bills Introduced.**—S. 188, to amend the chiropractic practice act, proposes to authorize the board of chiropractic examiners to license such chiropractors to practice physical therapy as have pursued a course of training of at least 200 school hours in physical therapy in some recognized institution and have passed an examination in physical therapy to be given by the board. The bill proposes also to permit chiropractors to practice in all state and public institutions and hospitals supported by public taxation, to treat the indigent sick at public expense, and to recommend admissions and releases and make reports in connection with the admission of patients to all state and other public institutions. S. 178 proposes, as a condition precedent to the issuance of a marriage license, the presentation of a physician's certificate that each party to the proposed marriage is "free from venereal diseases as nearly as can be determined by a thorough examination and by application of the recognized clinical laboratory tests of scientific search, when in the discretion of the examining physician such clinical and laboratory tests are necessary."

### MAINE

**Bills Introduced.**—S. 282 proposes to grant to hospitals, treating injured persons, liens on all claims and causes of action of such injured persons or their estates because of the injuries. S. 364 proposes to repeal present laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. S. 396 proposes to require physicians or hospitals treating persons

suffering from gunshot wounds to report the facts at once to the state department of health and to designated local police officials.

### MASSACHUSETTS

**Society News.**—The Boston Orthopedic Club was addressed, January 4, by Dr. Phillips F. Greene, dean, Human Yale Medical College (Yale-in-China), on "Experiences in China."—Dr. Siegfried J. Thannhauser, Boston, addressed the William Harvey Society at Beth Israel Hospital, January 15, on "Development of Our Knowledge of Metabolism."—At a meeting of the Greater Boston Medical Society, January 12, Dr. Charles R. Austrian, Baltimore, spoke on bronchiectasis.—Dr. Samuel A. Levine, Boston, discussed "Some Interesting Experiences of a Heart Specialist" before the Pentucket Association of Physicians in Haverhill, January 14.

**Dr. Washburn Appointed Superintendent of Hospital.**—Dr. Frederic A. Washburn, who recently resigned as commissioner of institutions of Boston, has been appointed superintendent of the Cambridge Hospital, effective March 1. He was born in New Bedford in 1869, graduated from the Harvard University Medical School in 1896. He served as assistant director of the Massachusetts General Hospital in 1899 and from 1903 to 1908, when he became director. When he retired in 1934 he received the title director emeritus. Dr. Washburn was also director of the Massachusetts Eye and Ear Infirmary from 1915 to 1934. In the latter year he was appointed commissioner of institutions. He has been a member of the Council on Medical Education and Hospitals of the American Medical Association since 1931. He served in the World War and was awarded the Distinguished Service Medal.

### MICHIGAN

**University News.**—Mrs. Emma Fox, parliamentarian for the Wayne County Medical Society, Detroit, conducted a class in parliamentary law for eight consecutive Fridays under the University of Michigan Extension Course. The course began January 15.

**Personal.**—Dr. Daniel W. Fenton, Reading, was honored at a meeting of the Jackson County Medical Society, January 19, when a resolution was adopted recommending him for honorary membership. The resolution was drafted by the Jackson and Hillsdale county medical societies; Dr. Fenton, who was secretary of the latter at various times, was unable on account of illness to attend the meeting at which he was to be guest of honor. Although 89 years of age, Dr. Fenton is still in practice.

**Bills Introduced.**—S. 106, to amend the workmen's compensation act, proposes to make compensable occupational diseases arising out of and in the course of an employment. The bill proposes to define an "occupational disease" as a "disease which is due to causes and conditions which are characteristic of and peculiar to a particular trade, occupation, process or employment." H. 192, to amend the workmen's compensation act, proposes to make compensable some fourteen stated occupational diseases and poisoning from some thirteen stated substances.

**First Hickey Lecture.**—Dr. Augustus W. Crane, Kalamazoo, delivered the first annual Hickey Memorial Lecture, February 1, on "Some Memorable Antecedents to the Discovery of the X-Ray." The lectureship was established by the Detroit Roentgen Ray and Radium Society in honor of the late Dr. Preston M. Hickey, professor of roentgenology, University of Michigan Medical School, Ann Arbor. Dr. Crane was president of the American Roentgen Ray Society in 1916 and in 1921 was awarded the gold medal of the Radiological Society of North America. Dr. Crane died suddenly February 20.

### MINNESOTA

**Bills Introduced.**—S. 666 and H. 866 propose a procedure by which hospitals treating indigent persons injured through motor vehicle accidents will be reimbursed by the state. S. 699 and H. 884 propose to authorize the governor to impose on "service trades engaged in rendering and performing personal services upon a person or persons and licensed and regulated as such by the state" codes of fair competition to establish standards of maximum hours of labor, minimum rates of pay and working conditions. This bill might possibly be construed as empowering the governor to impose such a code on physicians.

**Million Volt X-Ray Machine.**—Plans have been completed to install a 1,200,000 volt, constant potential x-ray therapy machine in the Charles T. Miller Hospital, St. Paul, according to *Minnesota Medicine*. It is expected that the

in age from 9 months to 10 years. With the exception of one child contaminated since birth, who died of tuberculous meningitis, all the rest are clinically cured over a period varying from three to fifteen years. The cure in all depended on immediate suppression of the infecting contact and possibility of exogenous infections, and hygienic treatment carried out since the primary infection and followed up until its complete cure.

Debré and Lelong of Paris insisted on the necessity of following all cases of apparently benign tuberculosis in infancy throughout their adult life, because severe forms may develop during the latter period although the attack in infancy was a mild one.

All those who took part in the second part of the symposium were of the opinion that immediate separation from any source of contagion, a strict and prolonged cure and continuous surveillance of all tuberculous subjects should be carried out.

#### Minister of Public Health Opposed to State Medicine

At the annual banquet, December 20, of the National Federation of Medical Syndicates, which looks after the public relations of the profession, the principal speaker was Mr. Henri Sellier, minister of public health. He is a socialist and an ardent advocate, like other members of the present cabinet, of universal state ownership or control; hence it was gratifying to the representatives of the medical profession present at the banquet to hear Mr. Sellier declare that he was strongly opposed to any attempt that would make every physician a state official, as proposed by some of the more radical members of the majority of the present government. Mr. Sellier said that his department wished to cooperate to the fullest extent with the medical profession. No steps would be taken in public health matters without ample consultations. Every attempt to interfere with the material and moral prerogatives of the profession will be opposed by him, because no one is more aware of the tragic situation of physicians in France than he is. This was, however, equally true of all middle class citizens, who are less well organized than are those who earn their living by manual labor. Sellier stated that individual voluntary insurance has so successfully taken the place of obligatory state insurance in the United States that he believes the voluntary form could be regarded as superior to the compulsory form as carried out in France and a number of other European countries.

It is essential that every effort should be made to preserve the individual character of the medical profession in the form of organization as opposed to state medicine. It would, however, be a mistake for the profession to guard its individuality so jealously as to oppose the plans of the present government to organize preventive medicine with the cooperation of the profession. It is not the aim of the government to substitute free treatment, except in cases that require it, but rather to reduce the danger of disease to a minimum by establishing health centers throughout the country in which diagnosis and prophylaxis shall play the principal part. Public hospitals should receive only those absolutely unable to pay for medical services. This is especially applicable to large cities like Paris; but in smaller communities, some provision must be made to take care of those who are able to pay. Hence the tendency in France to allow public hospitals in rural centers to admit pay patients, whose fees for medical services will be distributed pro rata among members of the staff.

Sellier said he was fighting quackery with all the means at the disposal of his department. It is astounding to note the extent to which all forms of charlatanism have flourished in France with the aid, especially, of the press. In closing, the speaker made a plea for continued close cooperation of the organized profession and the public health authorities. The relation between the patient and the physician should never be disturbed by an attempt to make every member of the profession a government official.

#### BERLIN

#### The Economic Condition of Physicians in Germany

Especial interest attaches to a discussion of the economic condition of physicians by Dr. Kluge which recently appeared in the *Deutsches Aerzteblatt*, the official organ of the German medical profession. The author says that it is a mistake to think of German physicians as enjoying favorable economic circumstances. The exercise of a so-called more independent calling always entails a greater economic risk. A doctor's practice may fall off during economic depression, or he himself may be incapacitated by illness. Nearly every physician carries a burden of debt, the legacy of his years of professional training and becoming established in practice. The average age of physicians who died within the last three years was only 61. Saving to create a reserve for old age or illness is a necessity.

Therefore a minimal net annual income of 9,000 marks should not be considered too high. But even that would not permit putting by a sufficient reserve for old age or for the support of dependents. The question now arises: how much of a gross income is necessary to assure a satisfactory net income? A doctor's professional expenses will take on the average 40 per cent of his gross turnover. For example, in 1927 the gross income of the average German physician was 15,519 marks; professional expenses, estimated as consuming 40 per cent of the gross income, averaged 6,000 marks. Three fourths of these expenditures were for payment of taxes and for maintaining an automobile; the other fourth went for rental and maintenance of an office, for graduate studies and so on. This average 40 per cent of gross income expended is exceeded, however, by many doctors. Even a medium-sized practice necessitates the employment of assistants, owing to the vast amount of clerical work involved. This compulsory expenditure of 40 per cent of gross income is, however, readily overlooked by officials who attempt to estimate the average income of physicians because a civil servant is accustomed to think in terms of a net income and may in addition look forward to a pension. An insurance policy that would guarantee to the physician old age and disability benefits commensurate with those enjoyed by the civil servant through his pension would cost about 3,000 marks in annual premiums. This means that in order to provide for the necessities of life a doctor must have a total annual gross income of 18,000 marks.

But what is the actual situation? By far the most important single income of 90 per cent of all German physicians is from the sick insurance society practice. Income thus derived accounts for 75 per cent of the doctor's total income. This means that he must earn 13,500 marks at his insurance practice. What services must he perform to accomplish this end? If his activities are restricted to advice given at his office and to visiting patients in their homes, and if four fifths of these so-called basic activities consist in office examinations and the other fifth in visiting, four fifths of this 13,500 marks, namely, 10,800 marks, must be earned at the office and one fifth, or 2,700 marks, from the visits. The remuneration of an insurance physician per office examination averages 0.65 marks, that for a house visit 1.30 marks. Thus, to take in 10,800 marks, 16,600 office examinations are necessary and the earning of 2,700 marks in house visit fees would necessitate 2,070 such visits annually. This means a daily average of some fifty-five office examinations and seven visits. According to these estimates the physicians would be called on to treat 2,250 cases of illness annually. But actually there were in 1935 around 20,000,000 insured persons with a total morbidity (including relatives of the insured) of 2.7; the total number of illnesses was 54,000,000, the number of insurance physicians around 30,000. More precise calculations

**Card to Identify Diabetic Patients.**—The New York Diabetes Association has issued an identification card for diabetic persons who may suddenly become faint or unconscious. One side bears the name, address and telephone number of the person and the other the following legend:

The bearer of this card has diabetes and is using insulin. In case of sudden faintness or unconsciousness give 2 tablespoons of sugar dissolved in a glass of water and call a doctor.

**Lectures on Syphilis.**—A series of weekly lectures on modern methods of diagnosis and treatment of syphilis was begun at the New York Academy of Medicine February 3 and will continue Wednesday afternoons to March 17. The lecturers are Drs. Howard Fox, Louis Chargin, William Bayard Long, Isadore Rosen, Abernethy Benson Cannon, Charles Walter Clarke and Leo Spiegel. Practical demonstrations are being held in various hospitals in the boroughs of Manhattan, Brooklyn, Queens and Bronx.

**Beauty Shops Forbidden to Use Electrolysis.**—Removal of superfluous hair by any one other than a physician is now forbidden as a result of a recent decision against a beauty shop operator who was accused of practicing medicine without a license. Investigators from the state board of medical examiners had gone to the establishment and taken two treatments. Sol Ullman, assistant attorney general, who conducted the prosecution, said that the electrolysis operators take brief courses of instruction in so-called electrolysis schools, over which the state regents have no jurisdiction or supervision. Complaints have been made that in some cases the appearance of persons treated for superfluous hair by these operators has been permanently marred and facial disfigurement for life has resulted. On the basis of this court decision the board of medical examiners and the state attorney general plan a campaign to stop this use of electrolysis, according to the *New York Times*.

**Another Million Volt X-Ray Machine.**—A new x-ray apparatus capable of generating voltages up to 1,200,000 was dedicated January 13 at the Institute for Cancer Research of Columbia University. The new machine was developed from a similar apparatus built at the University of California for experiments in the bombardment of atoms. At California it was found that by a simple change of one essential part it was possible to make a compact and efficient x-ray machine of high voltage, according to *Science*. Such a machine was then built for the University of California School of Medicine and the Columbia apparatus is the second of the type. The improvement over previous machines of high voltage lies, it is said, in the fact that this one is completely enclosed in a steel tank which is continuously evacuated. The new machine uses 15,000 volts of alternating current electricity, which is stepped up by means of resonance transformers supplied with power generated by radio oscillator tubes. Five outlets for the x-rays are provided, four to be used for treatment of patients and one for research. A special building for the new x-ray unit was erected by Presbyterian Hospital at Broadway and One Hundred and Sixty-Eighth Street. The machine cost \$25,000; stainless steel was presented by the Allegheny Steel Corporation of Pittsburgh and free use of patents by the Chemical Foundation and the Research Corporation of New York. It was built by Frank M. Exner, physicist of the Institute of Cancer Research.

#### NORTH CAROLINA

**Bill Introduced.**—S. 174 proposes to make it the duty of parents or guardians to cause all children between the ages of one and six in their care to be injected with a preventive dose of diphtheria toxoid or toxin-antitoxin or such other immunizing agent as shall be approved by the state board of health.

**Sanatorium Heads Appointed.**—Dr. Hillis L. Seay of the staff of the North Carolina Sanatorium for the Treatment of Tuberculosis, Sanatorium, has been appointed superintendent of the Mecklenburg Sanatorium, Huntersville, to succeed Dr. John Donnelly. Dr. Seay was graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1930. —Dr. Samuel M. Bittinger, assistant superintendent of the North Carolina Sanatorium for Treatment of Tuberculosis, Sanatorium, will be director of the new Western North Carolina Sanatorium now under construction on the Black Mountain highway, near Asheville, it was recently announced. Dr. Bittinger was graduated from George Washington University School of Medicine, Washington, D. C., in 1918. Dr. Paul P. McCain, superintendent of the present state sanatorium, will have general supervision over the new institution (*THE JOURNAL*, Nov. 21, 1936, p. 1726).

#### OHIO

**Society News.**—Drs. William S. Keller and Harold F. Downing, Cincinnati, addressed the Clermont County Medical Society, Bethel, January 20, on "Trends in the Socialization of Medicine" and "Significance of Cyanosis and Convulsions in the New-Born" respectively. —Dr. Frank A. Kelly, Detroit, addressed the Clark County Medical Society, Springfield, January 13, on "Hernia, with Special Reference to Injection Treatment." —Dr. John P. Tucker, Cleveland, discussed "Deficiency Diseases in Clinical Practice" at a meeting of the Seneca County Medical Society, Tiffin, January 21.

**Annual Public Health Lectures.**—The seventh annual series of free public health lectures sponsored by the Academy of Medicine of Cleveland, the Albert Fairchild Holden Foundation of Western Reserve University and the Cleveland Medical Library Association began, February 21, with a symposium on syphilis. The symposium was presented by Drs. Clyde L. Cummer, Roy W. Scott and Louis J. Karnosh, all of the faculty of Western Reserve University School of Medicine. A symposium on cancer will be presented March 7 by Drs. Harry Goldblatt and Harry Hauser of the faculty of Western Reserve and Abraham Strauss of Mount Sinai Hospital. Dr. Stanley P. Reimann, director of the Research Institute of Lankenau Hospital, Philadelphia, will deliver the final lecture of the series March 21, on "Cancer: A Problem for Every One?"

**Bills Introduced.**—S. 329, to amend the medical practice act, proposes that its provisions shall not be construed "to apply to persons treating human ailments by prayer or spiritual means and who only practice religious tenets of their church as an exercise or enjoyment of religious freedom; provided that the laws, rules and regulations relating to communicable and contagious diseases and sanitary matters are not violated, and that quarantine regulations are not infringed upon; and further provided that the person or persons administering or making use of or assisting or prescribing such, rely on faith and prayer alone, and do not prescribe or administer drugs or medicines nor use manipulation or material means nor perform surgical or physical operations, nor assume the title of, nor hold themselves out to be, physicians or surgeons." H. 545 proposes to authorize the director of welfare to establish clinics for the treatment of residents of Ohio whose mental condition demands immediate care and treatment.

#### OREGON

**Bill Passed.**—S. 301 has passed the senate, proposing that "in all actions for damages for personal injuries resulting from the use of x-ray, radium, violet ray, artificial heat, permanent wave machines, and from all other electrical and mechanical devices and apparatus, in the treatment of persons, and which are under the exclusive control of the person administering such treatment, proof of injury shall constitute prima facie evidence of negligence."

**New Health Officer for Portland.**—Dr. Adolph Wein-zirl, epidemiologist of the health department of Baltimore, has been appointed health officer of Portland. He will succeed Dr. John G. Abele, who will become city epidemiologist. Dr. Wein-zirl was born in New Mexico and received his degree in medicine at the University of Oregon Medical School, Portland, in 1925. From 1926 to 1931 he was assistant health commissioner of Seattle and during the next two years took graduate work at the Johns Hopkins University School of Public Health and Hygiene. In addition to his work with the Baltimore health department, Dr. Wein-zirl has lectured at the University of Maryland on control of communicable disease.

**Bills Introduced.**—S. 323, to amend the law requiring applicants for licenses to practice any form of the healing art to pass examinations in the fundamental sciences, proposes that it "shall not be necessary for an applicant to obtain a passing grade in all of the required subjects in the first session of examination but that any applicant who shall obtain a passing grade of 75 per cent in each of three or more required subjects at the first session of examination shall be examined thereafter only in the subjects in which he failed." S. 324, to amend the naturopathic practice act, proposes that from each annual renewal license fee of \$15 collected from naturopathic licentiates, \$10 shall be made available to the board of naturopathic examiners, to be used exclusively for educational purposes and the general welfare of the public in such manner and at such times as the board may deem proper and from time to time direct.

became unfit later on during the term of service, a total of 40 per cent. Of the the men in active service and classed as fit, 50 per cent were hospitalized; that is to say, one soldier of every two was forced to spend some time in a military hospital during his period of service. The number of men exempted on the grounds of constitutional disability was in 1931 twice the corresponding figure for 1911. Of the men accepted as fit, one finds that nearly 20 per cent, a fifth of the personnel, presented bodily weight and chest measurements below the average.

### Surgery of the Sympathetic Nervous System

Before the Medicosurgical Society of Brabant, Dr. Govaerts discussed the surgery of the stellate ganglion, the center formed by the junction of the inferior cervical ganglion with the first dorsal ganglion. After an anatomophysiologic outline of the sympathetic nervous system of the cardiac region, Govaerts described the technic of intervention in angina pectoris recommended by Danielopolu: this treatment concerns the stellate ganglion. Leriche proposes in the same disease the ablation of the stellate ganglion; Govaerts feels that the effect of a stellectomy must be interpreted rather on the basis of an obliteration of the sensitive afferent visceral path. He has performed four operations on patients with angina pectoris, in two of whom cure was effected, in the other two amelioration. In three cases the intervention took the form of a stellectomy; in the remaining case he restricted himself to a "central disconnection of the stellate ganglion." Stellectomy as such does not modify the causal disorder but by providing the myocardium with a regular regimen it may lead to a diminution in the cardiac volume. This intervention is indicated after the failure of medicinal therapy in cardio-aortic and cardiac angina cases in which the condition of the myocardium is such that a satisfactory survival may be anticipated. Anesthesia of the stellate ganglion may furnish real alleviation of suffering in febrile coronary angina. Alcoholization of the ganglion furnishes only partial results and renders subsequent stellectomy difficult. In Raynaud's disease and in causalgia, ganglionectomies are at present the most effective surgical interventions.

### Sanitary Airports

Regulation of aerial traffic in the Belgian Congo has undergone complete reorganization with reference to the prophylaxis of the principal contagious diseases; that is, cholera, typhus, yellow fever and variola. Sanitary airports have been created. A sanitary airport is one that has been officially designated as such by the governor general and is organized and equipped as follows: The airport must have at its disposal at all times an organized medical unit to which at least one physician and several sanitary inspectors are assigned; this personnel need not be permanently present at the airport. There must be a place for medical examinations and facilities for the storage of suspected goods pending laboratory examination and for the transport of such goods if laboratory examination cannot be carried out at the airport. Further facilities make possible the isolation, transport and general care of the sick, the separate isolation of persons who have been exposed to contagion and the performance of appropriate prophylactic measures, either at the airport itself or in the vicinity. The airport must also be provided with the equipment indispensable for disinfection, disinsection, deratization and certain other measures prescribed by the present law, should a need for such measures arise. The airport must possess an ample supply of pure drinking water and the maximal sanitary drainage system for the removal of all refuse, ordures and used water; adequate protection against rats must also be provided.

In addition to the foregoing, an anti-yellow fever or sanitary airport should be located at a certain distance from the nearest inhabited center and be provided with a water supply system completely protected from mosquitoes, and attempts should be

made to rid the place of the insects by systematic suppression of the breeding places and destruction of mosquitoes at all stages of their development. The quarters of the aircraft crews and ground personnel and the buildings in which air passengers may be lodged or hospitalized must be protected against mosquitoes.

### ITALY

(From Our Regular Correspondent)

Jan. 15, 1937.

### Hospital Ships Used in Ethiopian War

During the Ethiopian war there were eight hospital ships, which made several round trips between Naples and Massawa. Some of the hospital ships were anchored at the port of Massawa and functioned as floating hospitals. The ship *Helouan* made twelve trips, during which it carried 1,961 patients and provided 30,934 days of medical treatment. The daily expense for each patient was 151.08 lire (about \$7.55), which corresponded to the items given in the accompanying table.

#### Daily Expense for Each Patient on Hospital Ship

	Lire
Freighting of the ship.....	71.81
Passage of ship through Suez Canal.....	6.46
Cost for each person crossing the canal.....	32.26
Cost of water, naphtha and benzene.....	19.12
Minor expenses and cost of extra work.....	00.41
Cost of medicine and professional services to patients	1.83
Cost of food and personnel.....	19.13

The ship has an air conditioning system, which moderates the tropical environment. Proposals to use the *Helouan* as a stationary hospital in the port of Massawa at the end of the war were not carried out because anchored ship hospitals in time of peace have various disadvantages: It is not possible to have the necessary stability of the boat to take care of certain patients and to perform certain operations. The ship has to be anchored very close to the pier so that the patients will not have to be carried in small boats a long distance from the pier to the ship. The disinfection of the ship in time of epidemics is difficult and the daily cost of ship upkeep is high. In normal conditions of colonization it is better to build an air conditioned hospital on land.

### Diagnosis of Extramedullary Spinal Tumors

Professor Pontano, in a lecture before the Accademia Medica of Rome, spoke on the causes of errors in the diagnosis of location of extramedullary spinal tumors. Myelography is of diagnostic value but its results may be erroneously interpreted. The most frequent causes of errors are the following: The tumor, as a rule, is seated several vertebrae above the point of location shown by the clinical examination. Lipoid myelography can be made only after more than four days after the time of lumbar puncture. The clinical, neurologic and roentgen examinations are of equal importance in the diagnosis of location of the tumor.

Professor Pilotti called attention to the importance of a comparison of the cerebrospinal fluid obtained by occipital and by lumbar puncture. The former may be normal, whereas the latter may show important changes, especially hyperalbuminosis without hyperostosis, presence of xanthochromic cells and rapid coagulation.

Professor Alessandri, surgeon of Rome, called attention to the fact that tumors are located higher than the spot indicated by neurologic examination. He verified the fact in several operations which he performed before iodized oil was brought into use in clinical practice. In some cases the tumor is located three or four vertebral laminae above the point indicated by

resigned because of ill health. Dr. Peyton M. Chichester, Clarendon, secretary of the Arlington County Board of Health, has been made assistant director of the bureau. Dr. Lonsdale J. Roper, Portsmouth, has been appointed director of the division of venereal diseases.

### WASHINGTON

**Bill Passed.**—H. 388 has passed the house, proposing to grant to physicians, nurses and hospitals, treating persons injured through the fault of others, liens on any claims, rights of action, judgments or compromises accruing to the injured persons because of their injuries.

**Bills Introduced.**—S. 333 proposes to create a commission to investigate the organization, operation and control of hospital associations, medical service bureaus and other organizations supplying medical, hospital or surgical care and to report its findings to the 1939 session of the legislature. H. 528 proposes to make it a crime, punishable by a fine of from \$200 to \$500, for any tax-supported, charitably supported or tax-exempt hospital or institution "to deny to any duly licensed doctor, physician, or surgeon of sanipractic, osteopathy, chiropractic, food science, psycho-therapy, mechano-therapy, optometry, physcul-topathy, medicine or surgery, the right to practice his profession in the hospital when called for by a patient." The bill states that its purpose is to "maintain an open door to all licensed physicians, surgeons, doctors, and practitioners on an equality with all licensed systems of treatment." H. 529 proposes to create a sanipractic physicians' examining board and to regulate the practice of sanipractic. The bill proposes to define sanipractic as "the science and art of applied prophylactic and therapeutic sanitation, which enables the physician to direct, advise, prescribe or apply food, water, roots, herbs, light, heat, exercises, active and passive, manipulation, adjusting tissue, vital organs and anatomical structure by manual, mechanical or electrical instruments or appliances; or other natural agency, to assist nature restore a psychological and physiological inter-function for the purpose of maintaining a normal state of health in mind and body." H. 548 proposes to repeal present laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. H. 571, to amend the state narcotic drug act, proposes to authorize the imposition of the death penalty on convicted drug peddlers.

### WEST VIRGINIA

**Bill Introduced.**—H. 277 proposes to make it a condition precedent to the admission of children to school that they be or have been successfully immunized against smallpox and diphtheria.

**The Jacob Schwinn Lecture.**—The Ohio County Medical Society has established the Jacob Schwinn Scientific Lecture as a mark of respect to one of its members. The first lecture was delivered by Dr. Russell C. Bond, Wheeling, February 19, on "The Thymus Gland." Dr. Schwinn, a native of Switzerland, has practiced more than fifty years in Wheeling. He has been president of the county society and of the West Virginia State Medical Association.

**Society News.**—At a meeting of the Lewis County Medical Society at the Weston State Hospital, January 12, the speakers included the following members of the hospital staff: Drs. Everett Walker, on "The Problem of Psychiatry in General Practice"; Percy P. Pharr, "Physical Aspects in Mental Cases," and Emanuel J. Cohn, "Treatment of Psychotics in Mental Hospitals."—Dr. John H. J. Upham, Columbus, Ohio, President-Elect of the American Medical Association, addressed the Ohio County Medical Society, Wheeling, January 22, on "The Increase in Heart Disease in Middle Life."

### WISCONSIN

**Committee on Syphilis.**—A special committee for a study of syphilis control has been appointed by Dr. Stephen E. Gavin, Fond du Lac, president of the State Medical Society of Wisconsin. Members are Drs. James C. Sargent, Milwaukee; Charles W. Giesen, Superior; Edward L. Tharinger, Milwaukee; William J. McKillip, Milwaukee, and Gunnar Gundersen, La Crosse.

### WYOMING

**Bill Passed.**—H. 265 has passed the house, proposing to prohibit the retail sale and distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases, except by persons licensed to do so by the state board of health, or by licensed physicians, chiropractors or osteopaths.

### GENERAL

**Board Examinations in Neurology and Psychiatry.**—The next examinations of the American Board of Neurology and Psychiatry will be held in Philadelphia June 2. Applications must be in the hands of the secretary before April 2. The secretary is Dr. Walter Freeman, 1028 Connecticut Avenue, Washington, D. C.

**Northwest Regional Conference.**—Dr. Roscoe L. Sen-senich, South Bend, Ind., was chosen president of the North-west Medical Conference at its annual meeting in Chicago, February 14, and Dr. Carl F. Vohs, St. Louis, was elected secretary. Indiana will act as host at the next annual meeting in Chicago. The program was devoted to three symposiums, and speakers included Drs. Eben J. Carey, dean, Marquette University School of Medicine, Milwaukee; Maurice H. Rees, dean, University of Colorado School of Medicine, Denver; Harold S. Diehl, dean, University of Minnesota Medical School, Minneapolis, and Olin West, Chicago, Secretary and General Manager, American Medical Association.

**Reward for Information About Kidnap.**—The Department of Justice is offering a reward of \$10,000 for information that may lead to the identification and apprehension of the person or persons responsible for the kidnaping Dec. 27, 1936, of Charles Fletcher Mattson, 10 year old son of Dr. William W. Mattson, Tacoma, Wash. The following description of the kidnap is given: 5 feet 7 or 8 inches tall, swarthy complexion, about 30 years old, had a slightly foreign accent. He did not stand erect, had a dimple in his chin, high cheek bones and hairy hands; his nose appeared to have been broken. Information concerning the identity or whereabouts of the perpetrators of this offense should be sent immediately by telephone or telegraph collect to the Federal Bureau of Investigation in Washington, D. C., or any of its local divisions.

**Pacific Coast Surgical Association.**—The twelfth annual meeting of the Pacific Coast Surgical Association was held in Seattle, Wash., and Victoria, B. C., February 24-27, under the presidency of Dr. Otis F. Lamson, Seattle. The speakers included:

Drs. Harold Brunn and Leon Goldman, San Francisco, The Problem of Bleeding Peptic Ulcer: Clinical Aspects and Surgical Indications.  
Drs. Harry Glenn Bell and Frederick S. Foote, San Francisco, Obstructive Jaundice: Further Studies on the Differential Diagnosis by X-Ray.  
Dr. William P. Kroger, Los Angeles, Surgical Mortality in Thyroid Disease.  
Dr. John M. Schmoele, Los Angeles, Surgery of the Right Colon with Relation to Arthritis.

At the dinner in Victoria, February 25, Dr. George W. Swift, Seattle, and K. Kawaiishi, Nagoya, Japan, discussed "The Method of Taking Roentgen Cinematography of Human Organs and Blood Circulation."

**Medical Bills in Congress.**—*Change in Status:* H. R. 5030 has been reported to the House with a recommendation that it pass, proposing to grant pensions and increases of pensions to certain soldiers, sailors and nurses of the war with Spain, the Philippine Insurrection or the China Relief Expedition. The bill proposes no pensions for contract surgeons who served during the Spanish-American War. *Bills Introduced:* S. 1634, introduced by Senator Pepper, Florida, proposes an annual appropriation of \$11,580,000 to enable states to establish, extend and improve services for educating physically handicapped children. H. R. 4797, introduced by Representative Thomas, Texas, proposes to amend the Social Security Act to provide a federal subsidy to assist states to care for needy individuals who are 18 years or more of age and who are permanently incapable of self support by reason of a physical disability or defect. H. R. 5013, introduced by Representative Rankin, Mississippi, proposes to restore certain benefits to World War veterans suffering with paralysis, paresis or blindness, or who are helpless or bedridden—benefits to which such veterans were entitled prior to the enactment of the Economy Act of March 20, 1933. H. R. 5046, introduced by Representative Boren, Oklahoma, proposes to make the Civilian Conservation Corps a permanent agency of the government and to extend to enrollees of the corps the benefits of the United States Employees' Compensation Act. H. R. 5121, introduced by Representative Barry, New York, proposes to authorize an appropriation of \$1,500,000 to erect a new veterans' hospital and diagnostic center in the county of Queens, city and state of New York. H. R. 5125, introduced by Representative Rankin, Mississippi, proposes to provide pensions for certain blind veterans of the World War. H. R. 5135, introduced by Representative Barden, North Carolina, proposes to authorize an appropriation of \$2,000,000 to erect in the county of Wayne, North Carolina, a fireproof veterans' hospital and facilities for regional office.

## Deaths

**Ward Andrews Holden**, New York; Medical College of Ohio, Cincinnati, 1887; practiced in New York City since 1890; formerly professor of clinical ophthalmology at the Columbia University College of Physicians and Surgeons; member of the American Ophthalmological Society; honorary surgeon at the Herman Knapp Memorial Eye Hospital; had served as consulting ophthalmologist at the Bellevue, Roosevelt and Manhattan State hospitals; connected with the pathologic institute of New York state hospitals; for some years previous to 1929 was joint editor of the *Archives of Ophthalmology*; for many years served as attending ophthalmologist at the Neurological Institute; wrote a section on "The Pathology of the Eye" in the American Textbook of Pathology in 1901; was awarded the Cartwright prize in 1893 for his essay on "An Outline of the Embryology of the Eye"; aged 70; died, January 24, of cerebral hemorrhage.

**Francis Rhodes Fry** ♂ St. Louis; St. Louis Medical College, 1879; professor emeritus of neurology at the Washington University School of Medicine, 1921-1937, clinical professor of neurology, 1911-1920, professor of neurology, 1910-1911, and professor of diseases of the nervous system, 1900-1910; professor of diseases of the nervous system, 1890-1899, professor of anatomy, 1888-1890, clinical lecturer on diseases of the nervous system, 1887-1890, and assistant demonstrator and demonstrator of anatomy, 1881-1888; St. Louis Medical College; member and past president of the American Neurological Association; member of the advisory board during the World War; aged 83; on the staffs of the Barnard Free Skin and Cancer Hospital and St. Luke's Hospital, where he died, January 25, of heart disease.

**Lamartine Griffin Hardman**, Commerce, Ga.; University of Georgia Medical Department, Augusta, 1876; Bellevue Hospital Medical College, New York, 1877; member of the Medical Association of Georgia; formerly governor of Georgia; member of the Georgia house of representatives, 1902-1907, Georgia senate, 1908-1910; member of the state fuel administration during the World War; formerly chairman of the board of education of Commerce; trustee of the Georgia State College of Agriculture and Mechanic Arts, Athens, the Southern Baptist Seminary of Louisville, Ky., and Shorter College, Rome; aged 80; died, February 18, in the Emory (Ga.) University Hospital, of arteriosclerosis.

**George Loughead Eyster**, Coral Gables, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; member of the Illinois State Medical Society; during the World War served as chairman of the draft board and chairman of the Red Cross Chapter in Rock Island, Ill.; one of the founders and fellow of the American College of Surgeons; formerly on the staff of St. Anthony's Hospital, Rock Island; aged 83; died, January 11, of uremia, obstruction of the right ureter and pyonephrosis.

**John Loring Johnson** ♂ Bangor, Maine; Columbia University College of Physicians and Surgeons, New York, 1914; president of the Maine Medical Association in 1935; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly member of the city council; aged 48; consultant, Presque Isle (Maine) General Hospital and on the staff of the Eastern Maine General Hospital, where he died, January 14.

**Robert Cunningham Myles**, New York; University of Louisiana Medical Department, New Orleans, 1874; member of the Medical Society of the State of New York, the American Laryngological, Rhinological and Otological Society and the American Otological Society; emeritus professor of rhinology and laryngology, one of the founders and was a member of the board of trustees at the New York Polyclinic Medical School and Hospital; aged 83; died, January 1.

**George Willard Green** ♂ Chicago; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; fellow of the American College of Surgeons; member of the Institute of Medicine of Chicago and the American Association of Railway Surgeons; aged 74; one of the founders and on the staff of the Ravenswood Hospital, where he died, January 24, of coronary occlusion and arteriosclerosis.

**Harold Hixon Brittingham** ♂ Cleveland; Harvard University Medical School, Boston, 1920; since 1936 assistant clinical professor of medicine, Western Reserve University School of Medicine, senior instructor, 1934-1936, demonstrator of medicine, 1923-1934, and demonstrator of physiology, 1922-1923; on the staff of the City Hospital; aged 42; died, January 6, in St. Luke's Hospital, of brain tumor.

**William Henry Kohler**, Milroy, Pa.; Jefferson Medical College of Philadelphia, 1887; member of the Medical Society of the State of Pennsylvania; past president of the Mifflin County Medical Society; formerly medical inspector of Mifflin County; served during the World War; aged 73; died, Dec. 11, 1936, of cerebral embolism due to valvular heart disease and arteriosclerosis.

**David Allen Garrison** ♂ Gastonia, N. C.; Louisville (Ky.) Medical College, 1896; fellow of the American College of Surgeons; past president of the North Carolina Hospital Association and the Gaston County Medical Society; at one time member of the state legislature; medical director of the Garrison General Hospital; aged 71; died, January 14, of coronary occlusion.

**Charles Dilworth Kelly**, Blair, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; connected with the health department in Chicago as a dairy inspector, 1905-1908; aged 64; died, February 21, in the Woodlawn Hospital, Chicago, of hypertrophy of the prostate, myocarditis and acute urinary retention.

**Ethel Barnetta Cosby Adler** ♂ Woodmere, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1919; on the staffs of St. Joseph Hospital, Far Rockaway, Meadowbrook Hospital, Hempstead, and the South Nassau Communities Hospital, Rockville Center; aged 41; died, January 12, of carcinoma of the descending colon.

**Wright Butler Bean**, Stafford Springs, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Connecticut State Medical Society; president of the Tolland County Medical Society; aged 71; on the staff of the Cyril and Julia C. Johnson Memorial Hospital, where he died, January 18.

**Elmer K. Avery**, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; formerly medical examiner for the John Hancock Life Insurance Company; aged 62; for many years a member of the staff of the Norwegian-American Hospital, where he died, February 21, of coronary thrombosis.

**Otto Theodore Gunther** ♂ Sheboygan, Wis.; Rush Medical College, Chicago, 1911; fellow of the American College of Surgeons; served during the World War; surgeon and chief of staff, Sheboygan Memorial Hospital, and surgeon to the Sheboygan Clinic; aged 51; died, January 26, of coronary thrombosis and cerebral embolism.

**Harrison Arthur Coleman** ♂ New Philadelphia, Ohio; Western Reserve University Medical Department, Cleveland, 1910; served during the World War; past president of the Tuscarawas County Medical Society; past president of the city council; on the staff of the Union Hospital, Dover; aged 50; died, January 9, of heart disease.

**Daniel H. Meeks**, Nicholls, Ga.; University of Georgia Medical Department, Augusta, 1900; member of the Medical Association of Georgia; past president of the Coffee County Medical Society; formerly member of the state legislature, county board of education and mayor of Nicholls; aged 61; died, January 5.

**Charles Dorrance Busby** ♂ Brooklyn, Iowa; Marion-Sims College of Medicine, St. Louis, 1897; past president of the Poweshiek County Medical Society; served during the World War; aged 66; president of the staff of the Community Hospital, Grinnell, where he died, January 8, of streptococcal wound infection.

**George Arnold Boyd** ♂ Colorado Springs, Colo.; Bellevue Hospital Medical College, New York, 1890; president of the Colorado State Medical Society, 1925-1926; aged 72; on the staffs of St. Francis and Beth-El General Hospital, where he died, January 15, following operation for malignancy of the ileum.

**Charles Vincent Niemeyer**, Union City, N. J.; University of Vermont College of Medicine, Burlington, 1912; member of the Medical Society of New Jersey; fellow of the American College of Physicians; on the staff of St. Mary's Hospital, Hoboken; aged 48; died, January 11, of myocarditis.

**Henry Lewis Wagner**, San Francisco; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1884; member of the American Laryngological Association and American Laryngological, Rhinological and Otological Society; aged 77; died, Dec. 27, 1936.

**Charles Edwin Briggs**, Cleveland; Harvard University Medical School, Boston, 1897; formerly associate professor of surgery, Western Reserve University School of Medicine; fellow of the American College of Surgeons; aged 65; died, January 30, in the Lakeside Hospital.

At the opening ceremony Lord Rutherford, the physicist, congratulated the hospital on the installation. He referred to the slow but steady development of x-ray tubes, which had made possible the high powered apparatus now on view. Working at a million volts, rays could be produced which would equal in wavelength the gamma rays of radium. He emphasized the fact that the gamma rays of radium were identical in nature with the x-rays. He was certain that beams of gamma rays and of x-rays of the same wavelength would produce identical effects. The energy of the shortest wavelengths of the gamma rays of radium would correspond to a maximum of 2,000,000 volts, but the average corresponding voltage for the complete spectrum of these rays would be only about 600,000 volts. A beam could be produced from the new high voltage installation which would approximately be the same in quality as a beam of gamma rays, but of much higher intensity. He therefore looked forward to a comparison of the results that would be obtained with those of the radium beam research at the Radium Institute, with which he had been associated.

### The Annual Hygiene Congress

The twenty-third Annual Hygiene Congress was held at the Pasteur Institute Oct. 19-22, 1936. The symposium on associated vaccinations was of special interest.

The first paper, by Dopter and Sacquépée, medical inspectors of the army, and by Professor Pilod of the Val-de-Grace Military Hospital, was on associated vaccinations in the army. Vaccinations, they said, although indispensable in the army, should be as few as possible. The Ramon-Zoeller anatoxin method has enabled army surgeons to solve this difficult problem. Since 1930, triple vaccination (typhoid-paratyphoid A and B-diphtheria) was at first used in three, more recently in two, injections, the latter as soon as a sufficiently efficient diphtheria anatoxin was discovered. The reactions which have been observed do not differ from those following the use of the typhoid-paratyphoid A and B vaccine alone. The results have been highly satisfactory. The number of cases of diphtheria among vaccinated soldiers is extremely small and they are mild. Often the cases are only a simple pharyngitis occurring in diphtheria bacillus carriers. Although antidiphtheria vaccination has not been carried out as yet throughout the army, the number of reported cases has already appreciably diminished. Triple vaccinations in three injections are followed by about the same reactions as the two injection method. At present the results can be evaluated only from the serologic standpoint, because the application of the associated vaccination method has been too limited and too recent to permit conclusive epidemiologic deductions to be made. The serum of nearly all (99.58 per cent) of those who have been vaccinated against diphtheria shows the presence of sufficient antitoxic power to insure, in all probability, an immunity. In about 10 per cent of those given the diphtheria anatoxin, the antitoxic power seems to be lowered. As to tetanus, as far as one can judge by comparison with horses it appears as though the degree of antitoxic immunity obtained following the use of the Ramon tetanus anatoxin is sufficient to assure immunity in nearly all the injected soldiers for at least a year.

The second paper was by Loiseau and Laffaille of the Pasteur Institute and reviewed ten years' experience in adults with associated vaccination against typhoid infections and diphtheria. After having shown the absence of any danger of this method, they found that the association of different antigens (diphtheria anatoxin, typhoid-paratyphoid vaccine) seems to have a reciprocal reinforcing action. The number of those who have been immunized with the associated vaccines is much larger than

was the case when the typhoid-paratyphoid vaccine and the diphtheria anatoxin were employed separately. This method of polyvalent immunization, the efficacy of which has been proved over a sufficiently long period, ought to be followed, at least so far as the antidiphtheria immunization is concerned, under Schick reaction control. It ought to be adopted as a prophylactic measure for physicians, medical students and hospital personnel, especially in the case of nurses exposed to diphtheria and typhoid infections.

The final paper was on associated vaccinations in veterinary medicine, by Descazeaux of the Government Veterinary College.

In the discussion, Debré and Bonnet, in speaking of accidents during antityphoid vaccinations, stated that they were infrequent but at times severe in the form of prolonged syncope, marked fall of blood pressure, almost imperceptible pulse and heart beats. Rapid improvement follows the injection of epinephrine, but the signs of prostration may continue for a week. Although such reactions are well known, it is advisable to employ epinephrine by mouth as a prophylactic measure against such accidents. Following injection of the vaccine, the patient should be watched for the symptoms and epinephrine immediately given subcutaneously when the first signs appear.

### Joint Meeting of Pediatric Societies

A joint meeting of the Pediatric Society of Eastern France with the Swiss, Belgian and Paris pediatric societies was held at Strasbourg Nov. 8, 1936. The subject was "Primosecondary Tuberculosis of Infancy." Professor Rohmer of Strasbourg, in opening the meeting, insisted on a distinction being made between an allergy consecutive to a primary infection and an antituberculosis immunity in speaking of the prognosis and treatment.

Ribadeau-Dumas of Paris placed the factors which have an influence on the evolution of tuberculosis in its recent forms in two groups: 1. The primary conditions, which influence contagion and its modalities, taking also into consideration the allergic possibilities of the infected child. 2. The secondary conditions, such as environment and health of the child, the rôle of which is important but difficult to define. The first of these two groups of factors is the more important one because it emphasizes the fundamental part played by contagion and governs the rules of prophylaxis. Statistics covering the last thirty years show a decrease of infantile tuberculosis morbidity as well as mortality from tuberculous meningitis, whereas primary gangliopulmonary lesions in adolescents and adults have become more frequent.

Nobécourt of Paris finds that the prognosis is unfavorable during the first year of life but less so in the two following years. After the age of 6 years, tuberculosis is usually curable.

Armand-Delille of Paris has succeeded experimentally by direct intrapulmonary inoculation in obtaining lesions comparable to those in primary infections of very young children. All stages from generalized to distinctly localized forms can be observed, depending on the dosage employed.

Lesné, Dreyfus-Sée and Lemaire of Paris pointed out the thermal instability of infected children in whom sudden lowering of temperature occurs with slow rise. Ordinary infections are poorly supported. Such children ought to be kept in a preventorium during the entire period of organic instability.

Woringer of Strasbourg called attention to the frequency of phlyctenular keratoconjunctivitis in the early stages of infantile tuberculosis. Positive skin reactions were found in 90 per cent of such children, and this eye disease is often one of the earliest signs of tuberculosis.

The second question to be discussed at this meeting concerned the future of children presenting primosecondary evidences of tuberculosis.

Rohmer and Vallette of Strasbourg reported that they had been able to follow up, since 1919, twenty-six patients varying

## Correspondence

### "CLINICAL SIGNIFICANCE OF AURICULAR FIBRILLATION"

*To the Editor:*—In THE JOURNAL, Dec. 26, 1936, page 2099, appears an article entitled "The Clinical Significance of Auricular Fibrillation," by Drs. Luten and Jeffrey. Their main conclusion, "In non-heart failure cases of the arrhythmia (auricular fibrillation) the administration of therapeutic doses of digitalis produces no slowing of ventricular rate," is rather a large bolus to swallow in spite of their statistics, since just that effect does occur, and so uniformly, that their conclusion is a bit startling.

I have no statistics to present in refuting the authors' conclusion, but it is contrary to what I see in daily practice in the hospitals and cardiac clinics, and I feel that a few lines in favor of good digitalis effect in these cases are indicated.

Digitalis has a fairly well known pharmacologic effect on the heart. Theoretically this effect should take place whether or not congestive failure is present, provided there is enough myocardium to respond and provided there are no neutralizing factors present. These factors in the main are thyrotoxicosis and toxemia or infection, cardiac or extracardiac. The more severe these neutralizing factors are, the less probability is there for typical digitalis effect on the pulse.

Since the authors compiled their statistics from the records (p. 2102: "In none of these cases without heart failure did the record give evidence of any slowing effect on the ventricular rate"), I assume that the pulse rate was taken and charted by the nurse. This obviously would introduce a grave error, since the experienced cardiologist always notes the ventricular rate at the apex, as well as the pulse rate in fibrillation. Even if I am assuming too much, and the electrocardiogram was the source of this information, there is another possibility of error. On page 2100 is the statement "In 280 cases there was evidence of toxemia or fever or both," rather a high incidence of neutralizing factors in a total of 431 cases, and probably a large proportion of them are included in the non-heart failure group.

The plea of the authors to treat the underlying etiologic condition rather than the arrhythmia itself is well taken, except that the great majority of instances of fibrillation occur in patients with chronic heart disease in the rheumatic, arteriosclerotic and hypertensive groups, in which adequate treatment is questionable in the light of our present knowledge. Certainly treatment of the arrhythmia may give good subjective and objective relief, even though not permanent. In the other cases, thyrotoxic and extracardiac groups, clearing up the original focus produces excellent results.

I feel that when the pulse (ventricular) rate does not come down with therapeutic doses of digitalis in cases of auricular fibrillation, with or without heart failure, one should look for thyroid disease or a toxic or infectious process somewhere in the body. When these are ruled out, the remaining cases are invariably in terminal heart failure with a bad myocardium.

LAWRENCE S. WARD, M.D., Niantic, Conn.

[Dr. Ward's communication was submitted to Dr. Luten, who replies:]

*To the Editor:*—Thank you for your note of January 11, enclosing the letter from Dr. L. S. Ward.

Dr. Ward disagrees with our observation that in cases of fibrillation with no evidence of congestive heart failure digitalis in therapeutic doses causes no reduction in ventricular rate. He does agree that in some such instances, i. e., in "thyroid disease or a toxic or infectious process," digitalis may not cause slowing. He did not note his observations of the rate

effect of the drug if administered in cases of the arrhythmia resulting wholly from nervous influences. In these cases also I believe he will agree that digitalis is unavailing.

After considering cases of fibrillation due to toxic and nervous influences, there remain few instances of the arrhythmia except the group in which the initiation of the disorder relates to the auricular muscle (as noted on page 2101 of the article to which reference was made). Cases due to muscular effects constitute by far the greater group, and it is in this group that congestive failure commonly is the precipitating cause. Since in these congestive heart failure cases of fibrillation digitalis produces slowing, it is agreed that in most cases of the arrhythmia slowing results from the administration of digitalis—unless, as Dr. Ward points out, toxic or other factors which increase muscular irritability counteract that effect of the drug which in congestive failure causes slowing.

This (slowing) effect appears to result mainly from the lessening of ventricular irritability, an effect which occurs only in cases of congestive heart failure. In other cases digitalis increases irritability (p. 2102). Although, as Dr. Ward states, "digitalis has a fairly well known pharmacologic effect on the heart," this is not the only instance of opposite effects resulting from its action under different conditions of the myocardium. This slowing effect of digitalis in heart failure cases of auricular fibrillation and its failure to cause slowing in other cases is discussed more at length in "The Relationship of Tachycardia to Cardiac Insufficiency" (*Am. Heart J.* 12:435 [Oct.] 1936). (Note the correction of line 14 of page 441, appearing in the November issue of the *American Heart Journal*.) In this article the objection raised by Dr. Ward regarding pulse rates rather than apex rates receives comment.

It appears to Dr. Jeffreys and me that the common failure to differentiate those cases of fibrillation in which slowing occurs, from the smaller group in which slowing does not take place, is due to two facts: 1. In most cases (i. e., cases of congestive heart failure) slowing occurs, and it has widely been taught that it is to be expected in all cases, no matter how produced. This notion still persists even though certain exceptions, as noted by Dr. Ward, are being recognized. 2. There is failure to differentiate cases from the standpoint of etiology. In many cases of early congestive heart failure the fact of the failure itself often is overlooked, and the cause of the fibrillation therefore is not recognized. Under such circumstances it is obvious that slowing from digitalis might be interpreted as generally applicable to all cases. If these considerations are kept in mind, we believe that there will be observed few cases of auricular fibrillation unquestionably free from congestive heart failure in which therapeutic doses of digitalis produce ventricular slowing.

DREW LUTEN, M.D., St. Louis.

### PATHOGENIC FUNGI

*To the Editor:*—In THE JOURNAL Dec. 19, 1936, an editorial on pathogenic fungi gives the impression that the cultural or physical demonstration of yeasts and other types of fungi from various lesions is all that is necessary to prove a causal relationship. The editorial was inspired because Whalen found in his private practice in twelve months seventeen patients with diseases in the oral and auditory tracts which were considered as verified fungal lesions.

In the last eight years I have made many cultures for yeasts and other types of fungi from oral cavities with and without lesions. It is unusual to find any type of lesion in the oral cavity from which yeasts cannot be cultured on the first attempt as well as on subsequent attempts.

Not only has the saliva been cultured but the gastric contents, and stools of large groups of patients with all types of

show that 1,700 cases fall to the share of each insurance physician. This means 500 cases fewer per physician; namely, a failure by 3,000 marks to meet the required minimal satisfactory income from the insurance practice estimated.

The following points have also to be considered. An office examination requires on the average about ten minutes; this means that fifty-five consultations would take up 550 minutes, or nine hours. A visit is estimated to require twenty minutes; seven such would thus consume some two and a half hours. The minimal working day for the insurance physician with an average load would be around eleven hours. But at this rate he earns, according to the foregoing computations, only three fourths of his necessary livelihood.

Now on the basis of actual figures the income from insurance practice activities amounted in 1935 to from 8,500 to 10,000 marks per physician. The actual income thus remains about 3,500 marks below the necessary minimum. Even if the total gross incomes of all physicians are taken into account, one arrives at a figure around 15,000 marks per physician, so here too there is a disparity of some 3,000 marks between actual and theoretically necessary income. If from this sum of 15,000 marks the 6,000 marks for average professional expenses is deducted, together with a further 3,000 marks for old age insurance, the physician is left with an average income of 6,000 marks. This amount will just suffice for the existence of a doctor and his family whose requirements are modest. If the incomes of some doctors are in excess of this figure, the incomes of others fall short of it and that means economic distress. The economic circumstances of a physician may be represented by a curve the vertex of which corresponds to the forty-eighth year of life, after which a decline sets in. Yet it is precisely at this time of life that the doctor is confronted with the task of providing for his children's education. It may be impossible for him during his remaining active years to save for his old age, as a part of his reserve must be used for educational purposes and for the expense of illness in the family and so on. Under these conditions a doctor probably will not be able to carry an adequate amount of life insurance, and by "adequate" is meant insurance with a value at maturity of from 70,000 to 80,000 marks. According to data supplied by 1,400 physicians, the average amount of life insurance carried by members of this group was only 35,000 marks and many among them carried less. Such a small amount of life insurance is absolutely inadequate. These various factors combine to prevent the physician from enjoying repose in his old age; he cannot even afford to retire from his insurance practice. Moreover, the widows and orphans of physicians nearly always experience economic distress even when every possible relief is accorded them by physicians' benevolent organizations.

The number of insurance physicians has decreased by more than 2,000 since 1933, owing in part to the expulsion of non-Aryans from the insurance practice and in part to the migration of doctors from independent practice into positions which pay a fixed salary, since the small income from a permanent salaried post and a decent pension in old age appear more alluring than the precarious livelihood of an insurance physician. Danger exists, however, that a diminution in the number of insurance physicians, although it may serve to increase the incomes of a few doctors, will make it impossible for the majority remaining in the practice to carry on the increased load of work.

An increase in the scale of the insurance physicians' honorariums has just been effected. At present there are 617 insured persons to each insurance physician; this number can perhaps be stretched to a maximal 750, which would signify a decline of about 25,000 in the number of insurance physicians. One may assume that this decline in itself is due to many influences: the low birth rates of the war years, the exclusion

of non-Aryans from the medical profession, the increased demands of the public health service and the army, the possibility of attaining officer's rank created by the initiation of two year compulsory military service and the increased opportunities for admission into technical professions.

The effort is now being made to establish a form of compulsory insurance through the medical organizations which should at least mitigate the most extreme economic want. But as long as the prospect of an adequate old age provision is lacking for most physicians, one should not speak of the good economic condition of the German physicians.

## BELGIUM

### The Need for Physical Education

The Société médicale belge d'éducation physique et de sports, founded in 1934, has as its objective, in addition to academic medical investigations, a furtherance of the study of those medical questions which relate to physical education and sports. The society is represented in the International Association for Medico-Athletic affairs. Members of the society took an important part in the proceedings of the association's convention held at Chamonix in 1934. Besides the laboratory plan presented by the Italian school (of Viola, Cassini and Benedetti) the society supported a practical simplified plan (Govaerts, Ledent). The Belgian society organized in 1935 with the cooperation of the Journées médicales of Brussels an international meeting of specialists from France, Italy, Rumania, Switzerland and Belgium. In the national sphere the society has been in collaboration with the Fédération médicale belge, the initiator of lecture courses given before professional organizations. A vade mecum of medico-athletic supervision for use of the practitioner has been placed in the hands of 5,000 physicians and adopted by numerous clubs and federations. The Société médicale belge d'éducation physique et de sports has been promoted to the status of medical advisory body to the National Physical Committee and the Belgian Olympic Committee. The committee entrusted to the society the function of a jury for the award of the grand prize for the best medical supervision, conferred for the first time in 1935.

The malnutrition of the Belgian population in occupied territory from 1914 to 1918 has had grave consequences. At the time of the armistice the resistance of the adult population had been encroached on; the weight of an average man had decreased 10 Kg. The growth of the children was likewise imperiled: children from 7 to 14 years of age in the schools of Brussels exhibited an average bodily weight equivalent to the loss of a year for boys and a loss of six months for girls. The average deficiency in height corresponded to six months for the boys and one-seventh year for the girls. Childhood morbidity reflected the profound deterioration of organic resistance that took place both during and after the war. Official examinations of militiamen show that height continues to increase, whereas weight and chest measurements are on the decrease and general robustness is lacking. The young men of today tend to grow taller and leaner. In the course of recruiting for the army it has been observed that robust young fellows whose fitness is unquestioned have appeared in decreasing numbers, whereas the numbers of the unfit have increased at an alarming rate. Between the two categories a new type of recruit must be considered: the young man of delicate appearance but seemingly sound, who "cracks up" after his first taste of the hardships incident to army life. In the year 1931, 32 per cent, approximately a third, of the men called up for military service were excused as unfit; 6 per cent turned out to be unfit at the beginning of their actual service and 2 per cent

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### THEORIES OF FORMATION OF RENAL CALCULI

To the Editor:—What is the present-day accepted theory as to the relation of diet and water ingestion in the formation of renal calculi? Please omit name.

M.D., Texas.

ANSWER.—The relation of ingestion of diet and water to the formation of renal calculi is not completely understood. It would seem probable that in the normal individual they have little or no influence. In the presence of abnormal metabolism, chronic infection or abnormality in the urinary tract, the diet may have a profound effect on the formation of renal calculus. It has long been suspected that a deficiency of vitamin A in the diet may be a factor in the formation of stone. But this has not been definitely proved and it appears not to play a significant part clinically (Vitamin A and Urinary Lithiasis, Report of Council on Pharmacy and Chemistry, THE JOURNAL, Dec. 14, 1935, p. 1983).

There is also clinical evidence to support the theory that stones may form as the result of ingestion of abnormal amounts of certain chemical elements with oversaturation of the urine. It would seem probable that an abnormally low threshold favors precipitation of such crystals in the urine of these individuals. Among other factors which may affect such precipitation in these patients is a tendency on the part of the urine to be either hyperacid or alkaline. Acidification of the urine so that the level of the *pu* is kept at 6.0 or less by means of diet, with or without medication, will often prevent precipitation of crystals of calcium phosphate in the urine of patients who have a tendency to repeated formation of phosphatic stones or phosphaturia.

There is much clinical evidence to suggest that a patient with recurring lithiasis may have some disturbance in metabolism. In patients who are suffering from the so-called uric acid diathesis and who repeatedly pass uric acid crystals and calculi in the urine, the metabolic equilibrium will frequently be restored by avoidance of foods with a purine content, and the formation of stones will cease. It is also well known that the formation of cystine stones can frequently be prevented by alkalization of the urine by means of a high alkaline ash diet, together with oral administration of sodium bicarbonate.

The influence of bacteria on the formation of stone is not definitely understood. It is recognized that certain bacteria have a tendency to split the urea and liberate ammonia, with consequent alkalization of the urine, which in turn permits precipitation of calcareous elements. In the presence of bacteria that have such tendencies, acidification of the urine with a high acid-ash diet, with or without acidifying drugs, will often overcome the infection, prevent alkalization, and stop the formation of stone.

The influence of ingested water on the formation of lithiasis in the urinary tract is apparently of little importance. It is possible, however, that a very high calcium content may be a factor in stone formation in patients with a low threshold. The theory that ingestion of distilled water would prevent the formation of stone or that it would dissolve stones has no definite basis.

### ARTIFICIAL PNEUMOTHORAX

To the Editor:—Please send me information on the proper manometric readings approved at the present time in giving artificial pneumothorax.

W. R. BEARDSLEY, M.D., Vandalia, Mich.

ANSWER.—There is no uniform opinion regarding the "proper" manometric reading in pneumothorax, but there are, roughly, two main groups with regard to the intrapleural pressure to be instituted. One group, believing in a more complete collapse of the lung, including cavities, have advocated and used pressures up to 10 + cm. of water or more, with a mean value of 5 +. This range would correspond roughly to from 600 to 1,200 cc. of gas. Sometimes these pressures have been used also to "force" the closure of cavities held open by string or band adhesions, and even to separate adherent pleural layers. Such maneuvers, however, are dangerous, particularly the latter, because of the risk of air emboli. Even without adhesions,

the higher pressures are subject to greater risks than are encountered in the moderate or low pressures. Effusions, for example, are more frequent when high pressures are used.

Because of these risks, there is a gradual tendency to use less pressure, especially on first instillation. This allows for a gradual adjustment to take place so that no abrupt strictures will be imposed on the return flow of blood and lymph. At the present time, therefore, a great number of operators keep the pressure on the negative side. An average (of inspiration and expiration) normal negative of from -10 cm. of water to -2 cm. is found to give satisfactory results, and even an average of -5 on first instillation. Such pressures correspond roughly to 300-500 cc. and 100-200 cc. of gas, respectively. These manometric readings represent the average distance of one column in the manometer above the other. Naturally, such instillations must be given more frequently. They must be repeated every other day to once a week. The object is to give just enough to collapse the lesion without affecting the surrounding lung. It has been designated a "hypotensive collapse" and is meant to select out the diseased tissue and produce a "selective collapse" of the involved portion. Such a procedure may be used successfully in unilateral disease but is paramount in bilateral involvement.

The theory for the "hypotensive" method is that there is more intrabronchial pressure required to inflate partly diseased lung, because of muscular spasm, weight of tissue and constricted bronchioles. If enough intrapleural pressure can be given, therefore, to balance the extra pressure required to inflate the diseased lung, it will remain collapsed while the normal lung around will still be inflated by the slightly reduced negative pressure.

In summary, it may be said that every case is a law unto itself but that in general low pressures, often repeated, are to be preferred. Occasionally, when a cavity is held open by adhesions, higher pressures may be used. Even here a pneumolysis will usually take care of the situation.

### DIFFERENTIAL DIAGNOSIS OF PAIN IN CHEST

To the Editor:—A man, aged 27, well nourished and of excellent physical development, for the past two and a half months has noticed that if he lies on his back at night, or if he falls asleep and turns over on his back, a sharp pain occurs over his heart. This pain is severe enough to awaken him. By turning to either side he can cause the pain to diminish gradually in intensity, and in fifteen or twenty minutes it disappears entirely. I have examined him on different occasions and have not been able to find anything that might be responsible for this condition. I removed his tonsils and for about ten days the pain was absent but it has now recurred with the same degree of intensity and frequency. X-ray examination of the chest was negative. I have given him glyceryl trinitrate to take at the time of an attack but it fails to give relief. Examination of the heart is negative. There are no heart murmurs or irregularities. The pulse rate is 72 per minute. He has never noticed the pain during the day, and vigorous exercise does not distress him in the least. He smokes moderately and does not use alcohol. At present he states that by using two pillows at night he has been able to sleep in any position without experiencing any pain. I should appreciate it if you would give me some information as to what the probable cause of this condition might be and some idea as to what may be employed in treatment.

M.D., Iowa.

ANSWER.—The history is too limited to rule out many of the possible causes of chest pains. It is doubtful that the attacks are cardiac in origin. The patient's age, the absence of pain on effort, the character of the pain, the failure to obtain relief with glyceryl trinitrate and the absence of signs of heart disease all point to some other cause. A Wassermann test, however, is indicated to rule out the remote possibility of syphilitic aortitis. Although roentgenograms of the chest are stated to be negative, it is not clear from the question whether the aorta was examined for early syphilitic involvement.

The occurrence of pain only when the patient lies on his back suggests involvement of the vertebral column or the intercostal nerves. Pain in lesions of the spine not uncommonly radiate to distant points, and the anterior part of the chest is frequently so affected. Pain such as this may be the earliest manifestation of tuberculous osteitis of the vertebrae. During the day, pain may be prevented by muscular rigidity supporting the spine, but during the relaxation of sleep it may occur with such severity as to awaken the patient. Similar pain may occur in osteo-arthritis and fracture of the dorsal column. These conditions may be difficult to diagnose in some instances. Roentgenograms in the lateral positions may prove helpful. The value of using two pillows at night in relieving the pain more readily fits with the idea of some such involvement. Every effort should be made to rule out the conditions mentioned.

Frequently a diagnosis of pectoral myalgia or pleurodynia is made to explain pains in the chest of unknown origin in patients of apparent good health. These muscle pains are usually

the diagnosis. The lipoid test is of value in locating the seat of the tumor. It has, however, some inconveniences and the results may be interpreted erroneously.

### The National Congress of Urology

The fifteenth National Congress of the Societa di Urologia was recently held at Trieste. Drs. Mario Bonino of Turin and Marino Novak of Trieste were official speakers on the topic "Early Diagnosis of Renal Tuberculosis." According to Dr. Bonino, the first symptoms of renal tuberculosis are the appearance of cystic disturbances in 45 per cent of the cases and of hematuria in 5 per cent. The diagnosis of the nature and seat of the renal lesion can be made by cystoscopy in many cases. A positive diagnosis is made by obtaining the urine by catheterization and testing separately the two samples bacteriologically. The researches for tubercle bacilli in the sediment give a variable percentage of positive results. Positive results are obtained in 80 per cent of the cases by adding alcohol to the urine. According to the speaker, the acid-fast bacilli of smegma are not a cause of error as frequently as has been stated in the literature. Direct roentgen examination, especially by intravenous pyelography, is of importance. Pyuria is a constant symptom, erythrocytes are almost always present in the sediment and frequently there is albuminuria.

Dr. Novak discussed the predisposing factor to renal tuberculosis. The infection reaches the kidney through the blood, except in certain cases of ascending infection through a vesico-renal reflux of urine or of lymphatic propagation from the ureters or the regional lymph nodes. The speaker reported results of microcultures in seventy-five cases in which he obtained positive results in 93.4 per cent of the cases, whereas by the method of direct examination he obtained positive results in 72 per cent. Microculture is a method for rapid identification of tubercle bacilli, of more value than the direct examination and the biologic test. In the seventy-five patients seen by the speaker there was a history of previous pulmonary tuberculosis in 21 per cent and of tuberculosis of the genital organs in 13 per cent. Discussions followed and many articles on the same subject were read.

Professor Bonanome of Rome presented statistics of 236 cases of renal tuberculosis compiled from 1925 to the present. Nephrectomy was performed in ninety-one cases, with three fatalities. The disease was unilateral in 191 cases and bilateral in forty-five. An early diagnosis is made only in exceptional cases.

Drs. Gironcoli and Bortolozzi of Venice made cultures in 102 cases of different diseases of the urinary tract. The speakers conclude that a diagnosis of exclusion of renal tuberculosis cannot be made by the negative results of the cultures.

According to Wildbolz of Berne, a diagnosis of renal tuberculosis has to be based on the presence of a triad consisting of bacilluria, pyuria and renal dysfunction. The sign of most important diagnostic value is the presence of tuberculous changes in the bladder.

### Deaths

Prof. Edoardo Perroncito, bacteriologist and parasitologist, professor emeritus of the Turin University and Doctor honoris causa in several foreign universities, died recently in Pavia. He made studies on bovine tuberculosis, lesions of which, as he found, are histologically analogous to those of tuberculosis in human beings. Dr. Perroncito identified the pathogenic bacteria of chicken cholera. He determined the cycles of evolution of *Ancylostoma duodenale* and of *Leishmania intestinalis*.

Prof. Giovanni Pascale, a senator and professor emeritus of the surgical clinic of Naples, died suddenly while he was performing an operation. He wrote articles on clinical medicine and surgery and devoted great activity to establishing centers for the treatment of tuberculosis and of cancer.

## RIO DE JANEIRO

(From Our Regular Correspondent)

Jan. 2, 1937.

### Lecture on Allergy and Immunity in Tuberculosis

Dr. Abelardo Saenz of the Institut Pasteur of Paris, in a recent lecture before the Academia Nacional de Medicina of Rio de Janeiro, spoke on allergy and immunity in tuberculosis. He discussed general and local allergic reactions, Koch's and Shwartzman's phenomena and the organic reactions of animals to tuberculin before and after tuberculinization. He also reported results of work performed at the Institut Pasteur by Roquet, Waldis, Nègre and himself. The allergic reactions are more intense to the inoculation of dead bacteria than to that of living bacteria. Terrain is a factor of importance in immunity because of the natural or acquired conditions of immunity or sensitivity to tuberculosis. He spoke also on the organic changes induced by BCG vaccine and showed photographs of experiments.

### New Hospitals

A new maternity hospital was recently opened to the public in São Paulo. It is a U-shaped, six story building. The laundry, sewing rooms, storerooms, the boilers and the dormitories for the nurses are located in the basement. The rooms for the parturients, each of which has three beds and a bathroom, are on the first floor. In all rooms there are electric contacts for the installation of telephones. On the second floor there are dormitories for the patients, delivery rooms, surgical wards, rooms for cradles and incubators for the new-born, ambulances of the Ness type, identification rooms and a department for the supply of mother's milk. The private rooms are on the third and fourth floors. The kitchen is on the upper floor.

The new Miguel Cuoto Hospital at Bairro da Gavea Street has been opened. The president of Brazil, the mayor of the city and several diplomats attended the ceremony. Medical services heretofore given to the public in the ambulatory dispensary of Copacabana will be given from now on at the Miguel Cuoto Hospital. The family of Prof. Miguel Cuoto presented the hospital with a bronze bust of Cuoto, which will be put in a place of honor in the building.

## Marriages

ELWOOD KING JONES, Nutley, N. J., to Miss Margaret Rita Shuck of Shenandoah, Pa., at Lansdowne, Pa., January 2.

CLARA REGINA GROSS, New York, to Mr. Frederick W. Beeton of Mount Vernon, N. Y., January 14.

CORNELIUS E. KLINE, Assumption, Ill., to Miss Claracille Vodde of East St. Louis, Nov. 26, 1936.

JOHN McKAMIE HARRY, Fayetteville, N. C., to Miss Sarah Katherine Currie of Parkton recently.

HENDERSON L. HOLMAN, Ozark, Ala., to Miss Floride Arwood of Enterprise, Dec. 18, 1936.

JAMES COBB LASLIE, Tuskegee, Ala., to Miss Martha Virginia Johnson of Tuscaloosa, Nov. 8, 1936.

JOHN FREDERICK MOORE to Miss Frances Margaret Rook, both of Bath, N. Y., January 17.

EMMET F. PEARSON to Miss Mary Louise Maxon, both of Springfield, Ill., February 20.

SIGMUND M. JACZACK, Philadelphia, to Miss Mary Perkinas of St. Clair, Pa., in January.

CLAUDE S. FINNEY to Miss Elizabeth Nolan, both of Spartanburg, S. C., January 9.

JAY L. HUTCHISON to Miss Hazel Pifer, both of Logan, W. Va., recently.

LEO H. HOEVELT, Chadron, Neb., to Miss Eunice Peterson recently.

decalcification of the skeleton is at all marked, replacement of these mineral salts cannot be anticipated within less than one to three years, and improvement must be so slow that little change can be noted from week to week. It may be advisable to continue with the back brace for from eighteen months to three years.

#### SYPHILIS AND TIC DOULOUREUX

*To the Editor:*—A married man about 48 years of age had a sort of chancre in the penis in 1932. A physician gave him two or three injections of nearsphenamine, and as the chancre dried out he did not report to the physician for further treatment and advice. About the last months of 1933 he developed acute pains in the left side of the face with slight swelling and a diagnosis of trigeminal neuralgia (tic douloureux) was made by a prominent physician. His blood was examined and at first reported erroneously negative for the Wassermann test. The physician treating him naturally did not treat him for syphilis, but after a course of treatment with the symptoms aggravating, the physician requested another Wassermann blood examination, and it was found 4 plus. Not content with this report of a laboratory specialist he sent a sample of blood to another laboratory, but similarly the report was 4 plus. He was then given a course of injections consisting of nearsphenamine, with bismuth, iodide, and mercury preparations alternating. The blood as the injections were being given was also being given Wassermann tests. After a series of injections, the original 4 plus Wassermann was reduced to 2 plus and ultimately negative, and the blood has been negative for more than a year ago until this time. The original acute pains also gradually disappeared, but now what is left is numbness of the left side of the face with paralysis, and at times there are attacks of acute pains in the region supplied by the facial branch of the left trigeminal nerve. He has been treated by various specialists, including syphilologists. He further states that he has undergone treatment with the electrical current to no effect and the roentgenologist reports that electricity could not restore the paralyzed parts. He is now under my care, and I am at a loss what to do. There is no tumoration in the left preauricular region nor are there any carious teeth in the jaw in the vicinity of the paralysis. The man never developed secondary manifestations of syphilis. Please advise me and omit my name.

M.D., Philippine Islands.

*ANSWER.*—Syphilis is but rarely a cause of tic douloureux. Occasionally patients are encountered who have trifacial pain and serologic evidence of syphilis, both in the blood and in the spinal fluid, in whom treatment for syphilis dissipates the pain. In these patients a localized syphilitic meningo-encephalitis probably was the cause of the pain. The inquirer did not describe the pain in sufficient detail to permit expression of an opinion as to whether his patient had trifacial neuralgia. The residual facial palsy, probably resulting from involvement of the seventh nerve, might be the result of a neurosyphilis. The spinal fluid should be examined in this case, and if the report is positive the treatment for syphilis should be continued. On the other hand, if the spinal fluid is negative and if the facial pain is becoming increasingly more severe, an alcohol injection might be advisable. The severity of the pain, irrespective of the serologic reaction, should not constitute a reason for continued treatment, as in the cases in which syphilis is the responsible factor the pain is usually relieved or disappears following several injections of arsphenamine. The status of the syphilis is the factor that should determine the need for further treatment.

#### DIFFICULTY WITH MASTICATION

*To the Editor:*—A patient of mine, aged 64 years, is married to a woman twenty years younger than himself. They have two children—a boy 5 and a girl 7 years of age. Both children and both parents are healthy and normal in every respect. The girl, however, has never masticated any food in her life. All nourishment has to be given strained, mashed and/or puréed. Various methods have been used in an attempt to get the child to chew, but without any success. Her dentition is progressing normally and she is several pounds over her ideal weight. Her intelligence quotient is high and her work at school is very satisfactory. Can you suggest any method of getting this child to chew?

A. L. BARROW, M.D., Pittsburgh.

*ANSWER.*—The answer to this query is obviously difficult. If the child, 7 years of age, has no physical defects in her oral cavity or in the muscles of mastication, she should sooner or later normally develop this universal physiologic function. One must also consider that she may have failed to develop the habit of mastication as the result of negativistic characteristics, probably of neurogenic origin.

For the sake of completeness, one should refer to spasm of the motor trigeminal nerve. The spasm may be tonic or clonic. Tonic spasm of the muscles of mastication may be caused by diseases of the pons, also in the beginning stages of acute bulbar paralysis, and in pontile tumors. As a matter of fact, spasm of the muscles of mastication is very rarely an isolated symptom. From the history given in the query there is no reference to muscular hypertonicity.

Devries calls attention to the fact that hypertrophied adenoid tissue tends to prevent nasal breathing and removes some of the forces that stimulate normal palatal development, producing also a subnormal degree of mastication (Abt, I. A.: *Pediatrics*, Philadelphia, W. B. Saunders Company 3:160). He points out further that a child, when nasal breathing is impossible, finds difficulty in masticating his food. He believes that a child cannot bite and masticate his food while he is at the same time attempting to breathe through his mouth. Devries believes that difficulty in mastication may originate from narrowness of the upper dental arch and palate. In cases in which a high, narrow "gothic" palate is observed he advises orthodontic treatment.

#### ETIOLOGY OF DENTAL CARIES

*To the Editor:*—A girl, aged 17 years, well proportioned, weight 140 pounds (63.5 Kg.), height 5 feet 5½ inches (165 cm.), has been informed by a dentist that she may have gland trouble, as her teeth have caries. The dentist states that the dentin is soft. The girl is never sick, her periods are normal, the blood pressure is normal, her appetite is good; in fact, she is the picture of health and is quite active in all things. What could cause the dentin to be so soft? Before her birth the mother had every care and everything that one could desire and she is also in perfect health. Neither parent has trouble with the teeth. She has had cod liver oil during periods of her life but the dentist claims she is still deficient in calcium. What is your opinion?

M.D., Pennsylvania.

*ANSWER.*—It is impossible to make a concise and authoritative answer to this question until the exact etiology of dental caries is understood. There are recorded cases of endocrine disturbance which appear to have been of etiologic significance in the production of dental caries, and similarly there are instances in which a marked deficiency of minerals, particularly calcium, in the diet appear to be of importance in causing the disease. This does not mean, however, that all cases of dental caries are caused either by endocrine disturbances or by lack of calcium. The carious lesions in the teeth appear to be associated with certain local environmental conditions which may be influenced by many secondary factors, of which the endocrine balance, the diet, the character of the oral secretion and the oral bacterial flora all seem to be of significance. It certainly cannot be said that the administration of calcium will produce an immunity to caries in all cases. It will, however, be of assistance in those cases in which a calcium deficiency exists. From the history presented, it would appear that this girl is slightly overweight for her age and height. The most common cause of these moderately overweight cases is an excessive intake of carbohydrate, and it is well known that excessive carbohydrate may predispose to the production of carious lesions. This would appear to be the most suggestive feature of the data presented. It is, however, inadequate, as the weight in proportion to the height and age must be considered with regard to other factors than those supplied.

#### PATHOLOGIC EFFECTS OF ALCOHOLISM AND HYPERTHYROIDISM

*To the Editor:*—What is the present accepted opinion of the pathologic effects of alcohol on the human body? What, exactly, is the opinion of hyperthyroidism as a factor in alcohol tolerance? I have a patient who is slightly hyperthyroid, with an associated diabetes insipidus and whose alcoholic tolerance is amazing. Does the diabetes insipidus exert any influence? Will the relatively large amounts of alcohol this patient consumes affect his tissues to a greater degree because of increased consumption or does his great tolerance also indicate increased resistance to the pathologic effects? May the temporary intoxicating effects of the drug, in a given case, be considered a criterion of the pathologic effect? Please omit name.

M.D., Alaska.

*ANSWER.*—The pathologic effects of chronic alcoholism on the human body include catarrhal gastro-enteritis, fatty infiltration of various organs, cirrhosis of the liver, vascular changes, neuritis and mental degeneration. Some of these results may not be pure alcohol effects but may be due to the form in which the alcohol is taken or the incidental habits of the alcoholic addict. Thus, the liver cirrhosis has been ascribed by some to the fusel oils imbibed by whisky drinkers, while others have blamed the overnutrition and lack of exercise characteristic of beer drinkers. (Sollmann, Torald: *Manual of Pharmacology*, Philadelphia, W. B. Saunders Company, 1932.) Alcoholic neuritis, on the other hand, has been thought by some to be due to inadequate nutrition and specifically to a lack of vitamin B, occurring in the type of alcoholic addict who is accustomed to taking most of his calories as well as his refreshment in liquid form.

According to recent work (Gettler, A. O., and Freireich, A. W.: *Am. J. Surg.* 27:328 [Feb.] 1935) the temporary intoxicating effects of alcohol depend on the concentration of alcohol

**Jacob Braun** • New York; Columbia University College of Physicians and Surgeons, New York, 1905; aged 54; on the staffs of the Broad Street Hospital, Harlem Hospital and the Park West Hospital, where he died, January 29, of undulant fever and streptococcus endocarditis.

**Albert Leslie Laing** • Escanaba, Mich.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1897; past president of the Delta County Medical Society; aged 68; medical director and owner of hospital bearing his name, where he died, January 4, of cerebral hemorrhage.

**John Aloysius Parker** • Chicago; Loyola University School of Medicine, Chicago, 1922; vice president and on the staff of St. Bernard's Hospital; on the visiting staff of the Evangelical Hospital; aged 42; died, January 16, of acute endocarditis and mesenteric thrombosis.

**Bertha Anne Clouse**, Columbus, Ind.; Northwestern University Woman's Medical School, Chicago, 1900; member of the Indiana State Medical Association; city school physician; aged 68; died, January 21, in the Bartholomew County Hospital, of meningitis.

**Fred Albert Sweet**, Waddington, N. Y.; University of the City of New York Medical Department, 1887; for many years head of the board of education and the board of supervisors; aged 74; died, Dec. 31, 1936, of myocarditis and acute bronchitis.

**Wesley William Hall Sr.**, Shelby, Miss.; University of the South Medical Department, Sewanee, Tenn., 1899; member, 1912-1924, and president of the state board of health, 1920-1924; aged 60; died, January 1, of cerebral hemorrhage and hypertension.

**Sherman H. Champlin**, Chicago; College of Physicians and Surgeons of Chicago, 1895; on the staff of the Garfield Park Hospital; aged 71; died, January 14, of chronic myocarditis and chronic arthritis.

**John William Earel**, Long Beach, Calif.; Rush Medical College, Chicago, 1895; served during the World War; aged 67; died, Dec. 31, 1936, of hypostatic pneumonia following cerebral hemorrhage.

**Samuel Frederick Gandelman**, Bethlehem, Pa.; Tulane University of Louisiana School of Medicine, New Orleans, 1928; aged 35; was found dead in bed, Dec. 1, 1936, of poison, self administered.

**Frank Alexander Gordon**, Los Angeles; Howard University College of Medicine, Washington, D. C., 1914; aged 48; died, Dec. 25, 1936, of heart block, myocarditis and anemia.

**Evelyn C. Hoehne**, Milwaukee; Hahnemann Medical College and Hospital, Chicago, 1887; aged 86; died, Dec. 31, 1936, in the Evangelical Deaconess Hospital, of bronchopneumonia.

**George Marion Hanson**, Salt Lake City, Utah; Yale University School of Medicine, New Haven, Conn., 1936; aged 26; died, January 15, of chronic myocarditis and acute nephritis.

**George Wood Huse**, Seattle; Harvard University Medical School, Boston, 1883; aged 81; died, Dec. 2, 1936, in the Mason Sanitarium, of coronary thrombosis and arteriosclerosis.

**Robert N. Henry**, Lake Village, Ark.; Louisville (Ky.) Medical College, 1893; past president of the county board of health; aged 68; died, January 4, of arteriosclerosis.

**Charles Wesley Riggs**, Cameron, W. Va.; Starling Medical College, Columbus, Ohio, 1900; aged 70; died, Dec. 25, 1936, of arteriosclerosis and coronary thrombosis.

**Ira Thomas Gabbert**, Caldwell, Kan.; Jefferson Medical College of Philadelphia, 1883; bank president; aged 84; died, Dec. 30, 1936, of bronchopneumonia.

**Obed Cooley**, Lexington, Ky.; University of Michigan Homeopathic Medical School, Ann Arbor, 1903; aged 67; died, January 20, of lobar pneumonia.

**George Stephens** • Mesquite, Texas; Barnes Medical College, St. Louis, 1897; aged 62; died, Dec. 19, 1936, in the Baylor Hospital, Dallas, of pneumonia.

**James W. Warring**, Linwood, Kan.; College of Physicians and Surgeons of Kansas City, Mo., 1873; aged 89; died, Dec. 4, 1936, of cerebral hemorrhage.

**Andrew Henry Elliott** • Avalon, Pa.; Jefferson Medical College of Philadelphia, 1896; aged 67; died, Dec. 25, 1936, of influenza and pneumonia.

**D. Edward Morgan**, Ansted, W. Va.; Eclectic Medical Institute, Cincinnati, 1908; aged 51; died, Dec. 31, 1936, of an injury received in a fall.

**Philip F. Hasley**, Flat Rock, Mich.; Detroit College of Medicine, 1891; aged 71; died, Nov. 29, 1936, in the Wyandotte (Mich.) General Hospital.

**John F. Worcester**, Duxbury, Mass.; Boston University School of Medicine, 1888; aged 72; died, Dec. 6, 1936, of cerebral hemorrhage.

**Charles Burwell Benson**, Troy, Ohio; Ohio Medical University, Columbus, 1898; aged 63; died, Dec. 15, 1936, of cerebral hemorrhage.

**James H. Hargrave Jr.**, Petersburg, Va.; University College of Medicine, Richmond, 1899; aged 60; died, Dec. 30, 1936, of pneumonia.

**Philip Victor Graham**, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1915; aged 46; died, Dec. 8, 1936, of pneumonia.

**Theodore H. Baldwin**, San Diego, Calif.; New York Homeopathic Medical College, 1875; aged 82; died, Dec. 9, 1936, of arteriosclerosis.

**Frank L. Harris**, Winona, Miss.; University of Tennessee Medical Department, Nashville, 1903; aged 58; died, Dec. 29, 1936, of nephritis.

**Nellie Norris Tilton**, Jersey City, N. J.; Boston University School of Medicine, 1902; aged 57; died, Dec. 20, 1936, of pulmonary edema.

**Delos De Witt Smith**, San Diego, Calif.; Jefferson Medical College of Philadelphia, 1894; aged 76; died, Dec. 24, 1936, of duodenal ulcers.

**Augustus W. Thompson**, Mineral Wells, Texas; Missouri Medical College, St. Louis, 1879; aged 82; died, Dec. 27, 1936, of carcinoma.

**Samuel Hall Wilcox**, Carlyle, Ill.; Missouri Medical College, St. Louis, 1890; aged 70; died, Dec. 21, 1936, of cerebral hemorrhage.

**James T. Simpson**, Holden, Mo.; Memphis (Tenn.) Hospital Medical College, 1882; aged 84; died, Dec. 20, 1936, of pneumonia.

**James O'Gallagher**, St. Louis; St. Louis Medical College, 1878; aged 80; died, Dec. 10, 1936, of myocarditis and hypertension.

or hypertrophied endometrium resulting from endocrine dysfunction. Treatment should be preceded by gross and microscopic examination of the tissue allegedly passed, and a dilation and curettage should be performed just prior to the painful period, not only to obtain curettings for study but also in the hope that simple dilatation of the cervical canal might prove beneficial. The usual medications should be tried, atropine 0.4 mg. or potassium iodide 0.65 Gm. three times a day for three days preceding the menses, acetylsalicylic acid or codeine. Estrogenic, gonadotropic or corpus luteum preparations might be tried if organic disease can be ruled out; such therapy is experimental and the results are not constant.

#### INTERSTITIAL CYSTITIS

*To the Editor:*—A nullipara past middle age was told two years ago by a competent urologist that she had "a severe, localized inflammation of the bladder, which was not an ulcer nor was it tuberculosis or cancer." At that time she received cystoscopic examination on several occasions and a prolonged course of irrigations with silver nitrate without subjective improvement. Since coming under my care three months ago her course has been afebrile but she is bedridden, with constant discomfort in the bladder region, the discomfort often becoming severe pain after urination or attempts to walk. There has never been hematuria; for three months the urine has been macroscopically clear and without sediment. Medical treatment essayed so far has included the use of atropine to the limit of tolerance, the use of various synthetic antispasmodics, rendering the urine alkaline with potassium citrate, rendering the urine acid with ammonium chloride and following with a course of methenamine, the use of boiled milk intramuscularly (the patient is rather debilitated), and the production of ketonuria for twelve days. Not one of these procedures has benefited the pain and the tenesmus. I assume that the patient has a chronic submucous cystitis. Can you suggest any other curative measures? What drugs (other than nonspecific analgesics) or measures might make the condition less painful? Please omit name.

M.D., Maryland.

*ANSWER:*—While it is difficult to make an exact diagnosis without a careful cystoscopic examination and other studies of the urinary tract, it would seem possible that the patient is suffering from a condition which has been variously called interstitial cystitis, submucous cystitis, Hunner ulcer and panmural fibrosis. If this condition is present, it will be found very difficult to alleviate.

Patients with this lesion obtain more relief by overdilatation of the bladder under anesthesia than by any other method of treatment. It is advisable to overdilate the bladder under cystoscopic inspection in order to make sure that the bladder mucosa is not ruptured too deep. Although relief is often limited to only a few months, it sometimes continues longer. In some patients the lesion is found on cystoscopy to be confined to one area and, when localized, suprapubic excision is often followed by relief. When there are several definite areas visible on cystoscopic examination, light fulguration sometimes alleviates the pain, although usually only temporarily. A few patients have had relief following presacral neurectomy, although the end results of this operation have been disappointing in most cases.

Many patients will gradually become tolerant to the submucosal lesion and in the course of time, as its acuteness lessens, they may complain but little of their vesical symptoms. Local treatment and oral medication are usually of no value. If gram stains or cultures of the urine show bacilluria, oral acidification of the urine, together with mandelic acid, may be of value.

#### LOCATION OF CEREBRAL LESION

*To the Editor:*—A man, aged 47, whose physical examination and Wassermann tests are negative, has a left cerebral atrophy with right homonymous hemianopic changes in the visual field, all of uncertain duration. The only reason that he can offer as to the cause is that he was burning away some metallic zinc with an acetylene torch and got the fumes in this lungs. Can this cause the condition mentioned? If not, what is the usual etiology? Please omit name.

M.D., New York.

*ANSWER:*—The information is hardly sufficient on which to base a definite statement. On just what basis the diagnosis of left cerebral atrophy is made is not clear. The only symptom that is given is changes in the visual field, and the type of this is not recorded. Assuming that he has either a quadriceps or hemianopic homonymous defect, one could localize the lesion either in the parietal or occipital lobe, depending somewhat on the exact characteristics of the defect. It does not seem at all reasonable that a cerebral lesion would occur as the result of fumes from an acetylene torch getting into the lungs. The most frequent cause for visual field disturbance, aside from syphilis, is cerebral tumor, abscess or vascular disease. Further tests and examinations should throw more light on the matter.

#### REMOVAL OF TEETH ROOTS AND CYSTS FROM JAW

*To the Editor:*—A woman, aged 72, had marked swelling of the left side of the face, hard, not suppurative, for ten days. Then x-ray examination revealed the presence of the root of a molar in the left side of the jaw (the tooth was extracted thirty years ago). Incision and drainage from the outside afforded relief. In three weeks incision was made in the gum and bone was removed so that the root was identified and loosened but not removed. Iodoform packs daily were used for ten days. Will the body treat this root (the lower tips are on the outer margin of the mandible) as a foreign body and eventually evict the root or will more efforts have to be made to lift it out? What is the danger of fracturing the jaw? Please omit name and address. M.D., Michigan.

*ANSWER:*—Usually the mouth tissues react toward roots as they do toward functionless teeth. That is, they generally "evict" them. This process is spoken of as an eruption process. By far the vast majority of fractured roots move to the surface, frequently in the early stages; this is hastened with an accompanying suppuration. The exceptions are curved root tips, or roots that have become fused to the alveolar process through excementosis. If the observation is correct that the swelling was not due to suppuration, then it can positively be stated that the swelling was the result of a cyst formation about the root. That being true, surgical intervention is definitely indicated. This should consist of the removal of both the root and the cyst wall, provided the cyst is not too large. If the cyst is quite large, a Partsch operation should be performed. In this type of operation the cyst is opened and the cyst wall folded into the oral cavity and sutured to the mucous membrane. The root should be removed. There is always danger of fracture of the mandible in the case of large cysts, both with or without operation. If no operation is performed, in time fracture of the mandible will result from pressure absorption.

#### BLOCKING NOISES FROM EAR

*To the Editor:*—What can be done to protect the ears of the men working in steam electrical plants where the coal is ground into powder? The rollers that crush the coal weigh two or three hundred pounds and run at terrific speed and they make a tremendous rumbling noise. Most of the men become deaf or partly deaf after working around these rollers for a good while. I want to know the best thing I can do to protect the hearing of these men. The noise here is the same as in cement mills. Please omit name.

M.D., South Carolina.

*ANSWER:*—It is practically impossible to prevent loud, intense noises from reaching the hearing mechanism. A great many types of obturators to close the external auditory canal have been suggested from time to time but none have been completely successful. Experience with hearing tests indicate that the finger moistened with water or glycerin and held snugly in the meatus is a good obturator; but for men who are engaged in work in noisy places, a fairly tight fitting pledget of cotton moistened with glycerin inserted into the external auditory canal would probably serve as well as any other appliance. Possibly the wearing of a rubber air-containing pad over the ear held in place by a head band might be of some service and might be worthy of a trial.

#### DIAGNOSIS OF GONORRHEA FROM SMEARS

*To the Editor:*—I am a laboratory technician who has been taught by a well known pathologist that a positive diagnosis of gonorrhea is based only on gram-negative intracellular diplococci. Recently I have been associated with a gynecologist who claims that intracellular diplococci are found only in cases of acute gonorrhea and that extracellular diplococci are sufficient to give a positive diagnosis, even in the presence of an abundance of contaminating bacterial flora, and sometimes without an abnormal number of leukocytes. What is your opinion? Va.

*ANSWER:*—For the diagnosis of gonorrhea by the stained smear, the Gram stain must be used and the technic of staining carefully followed.

In urethral smears gram-negative diplococci of coffee-bean shape may be considered positive for gonococci whether intracellular or extracellular. In vaginal and cervix smears only the typical intracellular organisms should be considered positive unless confirmed by culture. Other gram-negative cocci are often found in smears from the female genitalia. It is true that in acute gonorrhea the diplococci are mostly intracellular, whereas in the chronic cases they are frequently found outside the cells.

In the presence of many contaminating bacteria and few leukocytes, the finding of extracellular gram-negative diplococci does not necessarily indicate gonorrheal infection. The report should state "gram-negative diplococci resembling gonococci." In some cases, particularly those of a forensic nature, it is necessary to make cultures on special mediums before stating whether the infection is or is not gonorrheal.

pathologic lesions. If mere presence of organisms means anything, the etiology of many lesions is easily demonstrated. This is particularly true in one of the commonest diseases of man. Every patient with a cancer whom I have seen in my private practice in the last eight years has shown a positive culture for fungi, and material cultured from a considerable group of patients in the Brooklyn Cancer Hospital all gave positive results. There is usually one type of organism present. Because these organisms are so common they have until recently received inconclusive consideration. The cause of a disease is as common as the disease. Consideration of more than the physical presence of the organism is necessary. As estrogen has been demonstrated to cause cancer in certain localities, and as yeasts contain considerable quantities of estrogen, progress might result from greater interest in the physical presence of fungi if studied in relationship to their biologic products. The number of known products is a high one.

The editorial is timely and I hope that it will inspire deep interest in this subject. A problem certainly exists as to the true significance of these organisms. There is apparently a group of lesions that are caused by the organisms, and another group of lesions which are similar in their physical manifestations but are not altered by a type of management that will afford complete or partial relief in the comparable group. A study of the physical effects of the biologic products should aid in the solution of the problem. Yeasts have the faculty of autolysis, so that their endogenous and exogenous products should be studied.

J. ARTHUR BUCHANAN, M.D., Brooklyn.

#### THE USE OF ANTISYPHILITIC REMEDIES

To the Editor:—Dr. H. N. Cole in his article on "The Use of Antisymphilitic Remedies" (THE JOURNAL, Dec. 26, 1936) says: "As yet I am unwilling to recommend the indiscriminate use of acetarsone by mouth in the treatment of congenital syphilis. It is still too much in the experimental stage." This statement is emphatic and conclusive. It gives the reader the impression that acetarsone is of no value in the treatment of congenital syphilis.

My experience with acetarsone, after using it for the last six years at the Northwestern University clinic, is different. I am of the opinion that acetarsone by mouth is the ideal drug for the treatment of congenital syphilis in the infant. In older children, it is true, neoarsphenamine with a bismuth compound or acetarsone with a bismuth compound is better.

Although it is true that the use of acetarsone in this country has not been extensive, the American reports published within the last four or five years have shown that this drug is efficacious in the treatment of congenital syphilis in infants. The following list of articles is evidence:

- Abt, A. F., and Traisman, A. S.: Stovarsol in the Peroral Treatment of Congenital Syphilis, *J. Pediat.* 1:172 (Aug.) 1932.  
Traisman, A. S.: Treatment of Congenital Syphilis with Acetarsone (Stovarsol) by Mouth, *Am. J. Dis. Child.* 46:1027 (Nov.) 1933.  
Rosenbaum, H. A.: Stovarsol in the Treatment of Syphilis in Infants and in Children, *Am. J. Dis. Child.* 44:25 (July) 1932.  
Maxwell, C. H., Jr., and Glaser, Jerome: Treatment of Congenital Syphilis with Acetarsone (Stovarsol), *Am. J. Dis. Child.* 43:1461 (June) 1932.  
Rambar, A. C.: Syphilis and Prematurity, *J. Pediat.* 3:841 (Dec.) 1933.  
Rosenbaum, H. A.: A Survey of One Hundred Cases of Congenital Syphilis Treated with Stovarsol (Acetarsone), *J. Pediat.* 3:434 (Sept.) 1933.  
Coppolino, J. F.: Acetarsone in the Treatment of Congenital Syphilis, *Am. J. Dis. Child.* 48:272 (Aug.) 1934.  
Traisman, A. S.: Further Observations on the Use of Acetarsone in the Treatment of Congenital Syphilis, *J. Pediat.* 7:495 (Oct.) 1935.

Besides, a review of the European literature for the last ten years shows numerous articles, by outstanding syphilologists, in which acetarsone is recommended very highly.

Erich Hoffmann, one of the foremost authorities of the present day on syphilis, in a recently published article (*J. Pediat.* 9:569

[Nov.] 1936) says that while he has seen good results from combined neoarsphenamine-bismuth (or mercury) therapy with medium dosage (0.01 Gm. of neoarsphenamine per kilogram), recently stovarsol (acetarsone) treatment has been preferred by most pediatricians, gynecologists, and dermatologists and has been regarded as sufficiently efficacious.

Further in the same article he states that "according to most experienced syphilologists, intensive stovarsol therapy with dosage and duration adapted to the severity of the congenital syphilis is very effective and so efficacious that neither recurrences nor nervous involvements ensue." He states further that older infants and small children, as well as adults, should be treated by neoarsphenamine and bismuth. "In cases in which stovarsol is not sufficient, this treatment is to be advised and may be repeated once or twice, according to indications."

These statements by Erich Hoffman speak for themselves. Acetarsone has its place in the oral treatment of congenital syphilis in infants. This drug has passed the experimental stage. Its use should be encouraged, especially in clinics and hospitals, so that its true worth may be firmly established.

Dr. Cole's statement is too final. He does not give his reasons for refusing to recognize the value of this drug or the work and research by many European and American clinicians.

ALFRED S. TRAISMAN, M.D., Chicago.

Associate in Pediatrics, Northwestern  
University Medical School.

[The letter of Dr. Traisman was referred to Dr. Cole, who replies:]

To the Editor:—I have never denied that acetarsone is effective in the treatment of congenital syphilis. The difficulty, however, is that the dose that is effective is so near to the dose that causes severe reactions that it is felt that it is unwise to have this remedy employed indiscriminately. For example, among the authorities that Dr. Traisman mentions, the article by Maxwell and Glaser states that in their series of cases from one of the best university pediatric clinics in the United States there was one death and one severe toxemia following acetarsone. The death occurred after 7.68 Gm. of acetarsone over a period of thirty-four days. They quote Martin as having had two cases of flaccid paralysis after use of the drug. They conclude: "Acetarsone probably has a definite place in the treatment of congenital syphilis. That the drug cannot be used indiscriminately is amply demonstrated by the one fatality and the toxic manifestations that occurred in our small series. The exact position of acetarsone remains yet to be determined by those who have at their disposal sufficient clinical material and sufficient interest to follow cases carefully with a minimum of danger." The Council on Pharmacy and Chemistry has not seen fit as yet to endorse acetarsone for the indiscriminate treatment of prenatal syphilis.

Moreover, if Dr. Traisman will take the trouble to consult two recent authoritative books on syphilis (Moore, J. E.: *Modern Treatment of Syphilis*, Springfield, Ill., Charles C. Thomas, 1933), and Stokes, J. H.: *Modern Clinical Syphilology*, ed. 2, Philadelphia, W. B. Saunders Company, 1934), he will note that these authorities take the same attitude.

Acetarsone has undoubted value in the treatment of syphilis. The only question is whether it is worth the chance when one has other remedies that may be employed and that will be even as effective, for either sulfarsphenamine may be injected intramuscularly, a concentrated preparation being used, or either the sulfarsphenamine or neoarsphenamine in a concentrated preparation may be injected under the fascia of the scalp and will be absorbed readily in infants, producing little or no reaction.

I am glad that Dr. Traisman has brought up this point. Perhaps it was not clear enough.

H. N. COLE, M.D., Cleveland.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 22-24. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: *Basic Science*. Tucson, March 16. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical*. Phoenix, April 6-7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Medical (Regular)*. Little Rock, May 11-12. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Reciprocity*. San Francisco, May 9. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, April 6. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: Hartford, March 9-10. *Endorsement*. Hartford, March 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, June 28-29 (probable dates). *Medical*. Washington, July 12-13. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

ILLINOIS: Chicago, April 6-8. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, April 13. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

KANSAS: Topeka, June 15-16. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY: Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Medical (Regular)*. Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic)*. Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, March 9-11. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-204 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, April 6-7. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, April 20-22. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OKLAHOMA: Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Basic Science*. Portland, March 20. Sec., State Board of Higher Education, Mr. Charles D. Byrnes, University of Oregon, Eugene. *Medical*. Portland, June 15-17. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, Education Bldg., Harrisburg.

RHODE ISLAND: Providence, April 1-2. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Rapid City, July 20-21. Dir., Division of Medical Licensure, Dr. B. A. Dyer, State Board of Health, Pierre.

VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WISCONSIN: *Basic Science*. Madison, April 3. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical*. Milwaukee, June 29-July 2. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

##### SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, February 27, page 754.

### District of Columbia Reciprocity Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports 36 physicians licensed by reciprocity during 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Yale University School of Medicine	(1928)		Connecticut
George Washington University School of Medicine	(1929)		New York
Georgetown University School of Medicine	(1930)		Maine
New Jersey, (1932)			Louisiana
(1933, 3) Maryland, (1933, 2) Pennsylvania			Virginia
Howard University College of Medicine	(1911)		Missouri
(1928) Louisiana, (1935) Kansas			
Emory University School of Medicine	(1922)		Georgia

Indiana University School of Medicine	(1925), (1933)	Indiana
Tulane University of Louisiana School of Medicine	(1930)	Alabama
(1932) Louisiana		
College of Physicians and Surgeons of Baltimore	(1914)	Penna.
Maryland Medical College	(1905)	Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons	(1925), (1932), (1934)	Maryland
Washington University School of Medicine	(1930)	Missouri
Leonard Medical School, Shaw University, N. C.	(1906)	Penna.
Ohio State University College of Medicine	(1928), (1933)	Ohio
Temple University School of Medicine	(1927)	Penna.
University of Pennsylvania School of Medicine	(1917)	Penna.
Woman's Medical College of Pennsylvania	(1928)	Penna.
University of West Tennessee College of Medicine and Surgery	(1915)	N. Carolina
Medical College of Virginia	(1930)	Virginia
University of Virginia Dept. of Medicine	(1932), (1933)	Virginia

### California October Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held in Sacramento, Oct. 20-22, 1936. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Fifty-eight candidates were examined, 53 of whom passed and 5 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine	(1933)		76.9
College of Medical Evangelists	(1935)		76.1
84.7, (1936) 79, 80.2, 81.9, 83.3, 83.3, 85.1, 86			
Stanford University School of Medicine	(1933)		83.4
(1936) 77.8, 80.9, 83.4			
University of California Medical School	(1936)	83.6, 86.8	
University of Southern California School of Medicine	(1936)		84.6
University of Colorado School of Medicine	(1935)		81.4
Georgetown University School of Medicine	(1929)		76.7
Loyola University School of Medicine	(1936)		77.3
Northwestern University Medical School	(1935) 79.6, (1936)		85.7
Rush Medical College	(1935) 86, (1936) 77.3, 87.1		
University of Illinois College of Medicine	(1934) 83.6, (1936)		78.2
Indiana University School of Medicine	(1935)		78.7
State University of Iowa College of Medicine	(1934)		88.2
Johns Hopkins Univ. School of Medicine	(1931) 80, (1936)		84.2
Harvard University Medical School	(1935)		87.2
University of Minnesota Medical School	(1936)		87.8*
St. Louis University School of Medicine	(1936)		83.9
Washington University School of Medicine	(1936)		87
Creighton University School of Medicine	(1935)		80.3
82.3, (1936) 81.7, 83.6, 85.2			
Cornell University Medical College	(1936)		76.4
University of Rochester School of Medicine	(1936)		80.3
University of Oklahoma School of Medicine	(1935)		81.1
University of Oregon Medical School	(1936)	86.1, 86.9	90.8
Jefferson Medical College of Philadelphia	(1936)		87.3
Vanderbilt University School of Medicine	(1933)		83.7
Marquette University School of Medicine	(1936) 75.7, (1934)		84.9
University of Wisconsin Medical School	(1934)		77.3
McGill University Faculty of Medicine	(1935)	83.4, 84.3	

School	FAILED	Year Grad.	Per Cent
University of Arkansas School of Medicine	(1936)		72.8

relieved by rest or pressure and increased by exertion. Intercostal neuralgia is felt along the course and distribution of one or more of the intercostal nerves, and marked tenderness is elicited occasionally by pressure in the corresponding spaces.

The problem of diagnosis of obscure chest pains is difficult and in many cases impossible. The most that can be done in the latter case is to observe the patient at frequent intervals for evidence of organic disease. This must be done before one can feel satisfied in attributing pain to myalgia, pleurodynia or intercostal neuralgia.

#### HYPERTENSION

To the Editor:—Mrs. J. P., aged 40, white, was told about ten years ago that she had high blood pressure. Her complaints were "hot flushes" and occasional dizziness. The blood pressure since has ranged between 190 and 240 systolic, 100 and 140 diastolic. The patient states that she feels fine except for occasional attacks of tingling and numbness of one whole side of the body, usually the right side. She had one attack in 1935 and has had three attacks within the last two months. These attacks usually last from ten to thirty minutes and resemble a complete hemiparesis. She has received every known medicine used in hypertension, including iodides, nitrites, glyceryl trinitrate and aminophyllin. There is no known focus of infection. Kidney function tests are normal. The blood Wassermann reaction is negative. The blood chemistry is normal. The blood count is normal, as is the differential count. X-ray examination of the sella turcica is normal. The basal metabolism is plus 6. X-ray examination of the chest shows enlargement of the heart and hardening of the aorta. Cystoscopy and pyelography are normal. The patient is well built and well nurtured, weighs 130 pounds (59 Kg.) and is 5 feet 6 inches (168 cm.) in height. Her face is rather florid. The pulse is usually between 80 and 100 a minute. The temperature is normal. The eyes show a slight exophthalmos. The fundi are normal. The ears, nose and throat fail to show any focus of infection. The thyroid gland is not palpable. The chest is normal except for the moderate enlargement of the heart and of the aorta. The abdominal examination reveals nothing abnormal. Vaginal examination reveals a normal marital outlet, cervix normal, uterus slightly retroverted, ovaries and tubes normal. The deep reflexes are slightly exaggerated. The superficial reflexes are equal. There is no involvement of the cranial nerves. There are no pathologic reflexes. The blood pressure varies, as stated before, between 190/100 and 240/140 at various intervals throughout the day. She has never been ill and has never been operated on. The regional history is normal. In the family history there is the following of significance: The mother, who was also a hypertensive patient on a renal basis, recently had a "stroke" and is now completely paralyzed on one side. The older sister, who lives in another city, has exophthalmic goiter. In 1932 the patient was given crisscross irradiation to the thyroid with temporary beneficial effect. Recently, with all the latest contributions toward the etiology and cure of so-called essential hypertension, a surgeon wanted to operate abdominally on the patient. The patient was willing, but the surgeon probably changed his mind, for she has not heard from him in the last two years. She is willing to undergo any treatment that holds a promise of cure or at least of a cessation of the attacks of apparent hypertensive encephalopathy, for with the present condition the patient is necessarily almost completely abstaining from social activities. I do not think that she can be helped medically. She has had almost everything suggested by a multiple of doctors, including endocrine substances and estrogenic material. Is there any operative procedure that will be of benefit? Will a thyroidectomy be indicated? Please omit name.

M.D., New York.

ANSWER.—In this patient the familial tendency to hypertensive disturbances is clearly manifest. Such inherited vulnerability of the circulatory apparatus to exaggerated response to stimuli is beyond relief by medication or surgical intervention. Perhaps thorough and tactful inquiry into a possible source of emotional turmoil and conflicts may reveal some reason for the recurrent acute attacks. These attacks are, apparently, due to cerebral angiospasm, what Riesman (*Am. J. M. Sc.* 185:29 [Jan.] 1933) called "vascular crises." It is often impossible to be certain just what precipitates such episodes, but emotional reaction unquestionably plays a more prominent part than physical effort. Such attacks imply a highly irritable vasomotor mechanism.

There has been little progression of the disease over the last few years. If this is the case the therapeutic problem becomes primarily one of diminishing the intensity of the arteriolar hypertension, raising the threshold to stimuli and permitting the hypertrophied and hyperexcitable arteriolar musculature to rest. The soluble nitrites and alkyl nitrates are too transient in their effects to accomplish these objectives. Vascular sedatives such as bismuth subnitrate or sodium thiocyanate, used over a long period, offer more encouragement. Thiocyanate salts must be administered cautiously and with frequent determinations of the blood and urine thiocyanate content as outlined by Barker (*THE JOURNAL*, March 7, 1936, p. 762) for they are dangerous. The iodides are useless. Calcium medication has likewise proved to be disappointing even to its most enthusiastic advocates. If emotional stimuli are responsible for the vascular crises, prolonged medication with mild sedatives may be of great value in reducing the frequency and severity of the attacks.

Phenobarbital 0.03 Gm. three or four times daily or sodium bromide 0.65 to 1 Gm. three times daily may be continued for weeks with reasonable safety if the patient is observed regularly.

Operative procedures have little, if anything, to offer the patient. Total or nearly total thyroidectomy to reduce the basal metabolic rate to minus 20 or below would probably merely make her stupid and depressed. As there is no hyperthyroidism present it is not logical to associate the vascular crises with thyroid dysfunction. Subtotal adrenalectomy, done in two stages, although energetically advocated by a few, is far too radical and the outcome too precarious to be warranted. Denervation of the adrenal glands fails to accomplish more than a temporary reduction in the arterial tension. Bilateral thoracic and lumbar nerve root resection and also resection of the major and minor splanchnic nerves have been employed to produce loss of vasomotor control over large areas of the vascular tree. The reported therapeutic results, as measured by the actual improvement in the diastolic tension (the best guide to arteriolar tonicity), have been almost useless. Reductions in blood pressure range about 10 or 20 mm. in the diastolic tension. The surgical risk in all these operations is definitely not justified by the results. Furthermore, such operative approach is without logic; there is no convincing evidence that arterial hypertension is due to either an overproduction of epinephrine or excessive activity of the sympathetic nervous system. To depress one normal functional mechanism in an attempt to compensate for some other abnormality is not sound therapeutics. Experimental work reveals that with all the various sympathectomy operations the arterial tension of normal dogs is depressed for but a few weeks.

#### SENILE OSTEOPOROSIS

To the Editor:—I have a patient whose trouble I have diagnosed as senile osteoporosis. She is 65 years of age and has a marked progressive curvature of the spine. Her symptoms of severe pain on motion and inability to get up and around have progressively grown worse until at the present time she is confined to her bed even though she has been carefully fitted to a back brace. The latest roentgenograms showed the condition of the spine to be much worse than a roentgenogram taken by another physician six months ago. Would you be kind enough to write the present-day treatment of senile osteoporosis. Please omit name.

M.D., Massachusetts.

ANSWER.—In an elderly patient, osteoporosis that is severe enough to produce deformity of the spine and severe pain on motion, with decalcification progressing rapidly, should cause serious consideration of the possibility of malignant metastases or osteomalacia secondary to hyperparathyroidism.

The treatment of senile osteoporosis must be predicated on the theory of correcting the conditions that have produced it. Among these etiologic conditions are (1) calcium starvation or inadequate calcium in the diet over a period of many years, (2) faulty absorption of calcium salts from the bowel, (3) atrophy of bone resulting from diminished physical activity, or a combination of these factors.

Immediate relief of pain may be obtained by immobilization and very gradual extension of the spine on a Roger bed or a Bradford frame. It would be illogical to anticipate correction of the anteroposterior deformity, but the anterior edges of the compressed or wedged vertebrae may be separated sufficiently to relieve some of the friction irritation or pressure on spinal nerve roots.

Heat and massage to the entire body is soothing and may help to improve the peripheral circulation and tissue tone sufficiently to minimize the atrophic effect of this additional period of enforced immobilization.

A high calcium diet should include 1 quart of milk daily if the patient will tolerate it. Since calcium can be utilized only in combination with phosphorus, at least two eggs daily and frequent additions of sweetbreads and nuts also are recommended.

Medication should include calcium lactate 0.65 Gm. three times each day, increased to 1.3 Gm. three times daily after four weeks. Some form of vitamin D concentrate is recommended to aid in the absorption and utilization of the calcium salts. This should be taken at mealtime in divided dosage. It is safe to prescribe 10,000 units daily, the dosage being increased so that after six weeks if there is no evidence of hypervitaminosis, as evidenced by anorexia or other gastro-intestinal disturbances, the patient may safely take 50,000 units daily for an indefinite period.

After six weeks of complete rest on an extension frame or bed, the patient may begin to sit up and gradually become ambulatory, wearing a rigid back brace of the Taylor type.

It must be remembered that the optimal retention of calcium that can be anticipated is only 0.5 to 1 Gm. daily. If the

28.5 degrees and of relative humidity from 52 to 78 per cent did not seem to influence the loss. Knowing the total heat production and the loss by evaporation, the author had an opportunity to check with this apparatus the exactness of his formula for loss by radiation, conduction and convection. In one experiment he calculated by this formula a total heat loss of 3.528 calories per second, while the actual heat produced by the bulb was 3.6 calories per second. In another experiment the calculated loss was 2.14, the actual loss 2.1. There was, consequently, very good agreement. In two thirds of the experiments the agreement between heat production as measured by skin temperature and as measured by oxygen consumption was within 10 per cent; in eight experiments the difference was over 15 per cent. The greatest differences were noted when the rectal temperature changed considerably during the experimental period, and the author believes that a calculation of the changes in the heat content of the body is apt to give too high values when based on changes in rectal temperature: in other words, that the rectal temperature has changed more than the total body temperature. The author concludes that his method gives good results in the measurement of heat loss but that the measurements of heat production are apt to be somewhat inaccurate in cases in which the body temperature has changed during the experimental period.

**The Intellectual Functions of the Frontal Lobes: A Study Based upon Observation of a Man After Partial Bilateral Frontal Lobectomy.** By Richard M. Brickner, B.S., M.D., Assistant Professor of Neurology, College of Physicians and Surgeons, New York. Cloth. Price, \$3.50. Pp. 354, with 13 illustrations. New York: Macmillan Company, 1936.

In 1931, a year after both frontal lobes of the brain had been removed for a meningioma, the patient, whose history is recorded in this book, was 42 years of age. For the next year elaborate studies were carried out with the aim of investigating the deficit, if any, in the patient's mental processes. The studies were not only those conducted by highly technical experts in psychology and psychometric examinations but also studies based on ordinary conversations with the individual, under natural surroundings. In this monograph we have more data at hand with regard to what a patient said and did after removal of a part of his brain than have ever been accumulated in the past. This, moreover, is the first time that such data have been gathered following bilateral amputation of the frontal lobes. The material, therefore, is unique not only in scope but also in character. The exact amount of tissue removed is known, as well as the part of the brain from which it came. Although some of the conclusions drawn have been somewhat anticipated by other workers, this minute and painstaking survey adds greatly to our knowledge of the function of the frontal lobes. The deductions, moreover, are of such a nature and so clear cut in character that they give for almost the first time a fundamental concept of this part of the brain.

The deficit caused by the amputation of both frontal lobes in this patient did not alter in any way the fundamental nature of any mental process. There was, however, impairment in the completeness of function, with a quantitative rather than a qualitative loss. Only one function, moreover, was primarily affected—that of the power of association or synthesis of the simple engrammatic products from the other parts of the brain. There was thus a definite limit to the complexity of thought, which made a distinct change in the personality of the individual. There was nothing to indicate that the frontal lobe should be considered as an intellectual center the destruction of which will remove entirely a primary mental process. This interpretation, as given by Dr. Brickner, accounts for nearly all the symptoms shown by the patient. A few symptoms were unexplained on the basis of diminution of association or synthesis from other parts of the brain. These symptoms were a tendency toward rectal and vesical incontinence, slight euphoria, some compulsive acts, and jargon of speech. The explanation of these symptoms is left for future investigators.

Although Dr. Brickner has drawn these conclusions from a study of his patient, he has put the data collected both formally and informally in such form that different interpretations may be made by other investigators. The subject necessarily is one of the most complex in medicine, for the frontal lobe is by common consent the most dominant part of the brain. The data presented here advance our knowledge and we are greatly indebted to the author for his carefully recorded studies over

a long period. The observations, however, go only through the year 1932, the patient having been operated on in 1930. One would like to know the state of the patient's health at the present time and whether the studies have been continued. The effect, if any, of psychoanalysis in such a patient would also be worthy of record.

**Krebs und Krebsbekämpfung in Frankreich.** Von Dr. med. Hellmut Haubold, Reichsgesundheitsamt, Berlin. Herausgegeben in Gemeinschaft mit Unterstützung des Reichsausschusses für Krebsbekämpfung. Paper. Price, 15 marks. Pp. 273, with 19 illustrations. Leipzig: Johann Ambrosius Barth, 1936.

This monograph, the author of which is connected with the German health office, is written in order to spread the knowledge of the French campaign against cancer and to draw practical conclusions for the organization of the German cancer campaign. It is authorized by the official German committee on cancer campaigns. Based on personal studies in the leading French cancer institutes, the author discusses the leading ideas and the principles of the French anticancer organization. In the first part he gives a sketch of the historical development of the conceptions of cancer pathology in France, as far as the understanding of these is necessary for the reasonable organization against this disease. In the second part the statistical data regarding the incidence of cancer in France and its importance as a public health problem are extensively discussed and carefully compared with the international conditions in this regard. The book definitely loses some of its value by the fact that the information contained in it is not absolutely reliable. The author states, for example, on page 189 that the new cancer hospital of the Curie Institute in Paris is equipped with two x-ray machines with 200 kilovolts, one with 300 kilovolts and one with 700 kilovolts; whereas, as a matter of fact, at the present time there are seven 200 kilovolt machines and one 300 kilovolt machine in operation but no higher voltage machine is operating or has been planned for. It is obvious that a reference book of this type is of great value only if it is absolutely reliable in every detail. With this reservation the book gives an interesting cross section of the present situation of the cancer campaign in France, which is considered by many as the model organization in Europe with the exception of the organization in the Scandinavian countries.

**Home Care of the Mental Patient.** By Dr. Arle Querido, Head of the Department of Social Psychiatry, Medical Service, City of Amsterdam. With a foreword by R. D. Gillespie, M.D., F.R.C.P., Physician for Psychological Medicine, Guy's Hospital, London. Cloth. Price, \$1. Pp. 93. New York & London: Oxford University Press, 1936.

This pocket-size handbook gives a good deal of useful and interesting general information about the mental patient. It should give any reader a better and more sympathetic understanding of the sufferer with mental disease, as a patient. It should help to dispel the ignorance, which still persists, causing the insane to be regarded with fear, with aversion, or with a perverted sense of humor. But it will not give the reader much if any practical help in the home care of the patient. Sympathy, tact and understanding are excellent, but they are no substitute for knowledge. As an introduction to mental disease, written for laymen, it is a useful though by no means indispensable little manual. As a guidebook for the perplexed relative, it is virtually useless.

**Annual Review of Biochemistry.** Edited by James Murray Luck. Volume V. Cloth. Price, \$5. Pp. 640. Stanford University, California: Stanford University Press, 1936.

The Annual Review of Biochemistry has been in existence for more than five years. During this time it has become an indispensable guide to developments in biochemistry and to a less but still important extent in physiology as well. A review of these collected reviews is now almost superfluous. The present volume introduces both new subjects and new authors to readers of the previous issues. The subjects include oxidations and reductions; enzymes; x-ray studies of biologic compounds; chemistry of carbohydrates and glucosides, acyclic constituents of natural fats and oils, proteins, amino acids and other nitrogen compounds, sulfur compounds, phosphorus compounds and fungi; metabolism of carbohydrates, fats, amino acids, minerals, organic acids of plants and bacteria; vitamins; hormones; liver and bile; nutrition; animal pigments; special elements in plant nutrition, and soil microbiology. This mate-

present in the brain. When this concentration reaches 0.25 per cent, symptoms of intoxication appear regardless of the habituation of the individual to the intake of the material. The increased tolerance of habitual drinkers is therefore not due to any real acquired immunity to the effects of alcohol but rather to an increased rate of oxidation of this substance in the tissues, so that it requires a greater intake of alcohol to raise its concentration in the brain above the stated intoxicating level. Thus the degree of temporary intoxication caused by alcohol in a given case cannot be taken as a criterion of its permanent pathologic effects on the individual, and there seems no reason to believe that the patient mentioned by the correspondent has an increased resistance to these effects.

As regards the relationship of the hyperthyroidism in this patient to his great tolerance for alcohol, the obvious conclusion from the discussion would be that the increased tissue metabolism of hyperthyroidism disposes of large quantities of alcohol and retards the rise of alcohol concentration in the brain. Another factor may possibly be the high oxygenation of the blood in hyperthyroidism, since Keilin (*Proc. Roy. Soc. [B]* 98:312, 1925) has shown that high oxygen tensions counteract the impairment of the catalytic efficiency of cytochrome caused by alcohol.

Diabetes insipidus may also be a factor in the patient's resistance to the intoxicating effects of alcohol. Rowntree (*Oxford Medicine*, Vol. 4, part 1, p. 183) states that "idiosyncrasies to drugs may exist, particularly a tolerance for alcohol."

#### EFFECTS OF COITUS IN GONORRHEAL CONDITIONS

To the Editor:—Is coitus (with a condom, of course) beneficial, because of the complete evacuation of the prostate and seminal vesicular secretions, or harmful, owing to its irritating effects on the urethra and other glands in the following cases: 1. Subsiding gonorrheal arthritis, when the urethral discharge ceased three months ago, and urine (first and second) is crystal clear, and the joint aches are reduced to a minimum. 2. Postgonorrheal chronic prostatitis, when there is no urethritis, first and second urines are clear, and there are no symptoms except prostatitis confirmed by microscopic tests. 3. Mild chronic nonspecific urethritis and prostatitis of many years' duration, with an occasional urethral purulent discharge, the first urine slightly hazy with many shreds, the second urine clear, and the prostate containing innumerable white blood cells per high power field and feeling boggy grossly. No subjective symptoms are complained of. I should like to know whether intercourse should be advised or not in these types of cases. Kindly omit name.

M.D., New York.

ANSWER.—1. In this instance there is not sufficient proof that the gonococcus has entirely disappeared. Under these circumstances intercourse might be harmful.

2. If the statement that prostatitis is present means that the gonococcus has been demonstrated by microscopic tests, then again intercourse might be harmful.

3. Intercourse in all probability would not be harmful, but it is doubtful whether or not it would be beneficial.

#### ALLERGY OR CAPILLARY FRAGILITY

To the Editor:—A farmer, aged 35, seems to be in perfect health except when he does any unusual work that rubs the skin and the tissues beneath the skin. Then the tissues swell and become quite painful. As an example, he was putting window screens in and working around the house, standing on a stepladder and leaning against the upper step, so that it rubbed the tissues above both knees. This caused them to swell and cause great discomfort. As another example, in sitting on the seat of the tractor, where the seat rubbed the sides of his buttocks, the tissues swell and become quite painful. His tonsils have been removed, his teeth are in good condition, and no abnormal condition can be found in the rectum; in fact, no other pathologic changes can be found. Is this a form of allergy? If so, can anything be done to prevent the recurrence, other than avoiding such pressure? Please omit name.

M.D., Illinois.

ANSWER.—Two possibilities suggest themselves. There is a likelihood that the swellings are of a hemorrhagic nature, probably the result of capillary fragility. This could be on an allergic basis, although other causes should be kept in mind. Of course, the discoloration would be the significant diagnostic finding. The other possibility is that the swellings are of an allergic nature, i. e., urticaria or angioneurotic edema, and that the localization of the swellings is due to the trauma. From the description given, allergy should be considered. The most likely source of the allergy would be a food, which probably can best be handled by elimination diets. Bacterial sensitization and heat allergy (from rubbing) should also be considered. For the hemorrhagic type of swellings a calcium salt and viosterol should be tried. For the urticarial type injections of parathyroid extract may be of help.

#### TREATMENT OF SYPHILIS

To the Editor:—I have a patient, aged 68, who although he denies ever having had syphilis has had a one plus or two plus Wassermann reaction over a period of about ten years. His Wassermann reaction was not taken prior to this period. Ten years ago when the test returned positive he went to one of our large hospitals, where he had a spinal puncture done and the attempt was made to give intravenous therapy. He says this was given up because of the difficulty in the procedure because of the small size of his veins. He, however, was given repeated injections of a bismuth compound and during the last ten years these bismuth injections have been repeated fairly frequently. He says he has had negative Wassermann reactions following such treatment, only to have positive tests recur. He has been carefully studied by several good men; some have advised injections of bismuth preparations and the last one just digitalis and potassium iodide. A roentgenogram of his heart shows the apex at the sixth interspace, the left border 8.9 cm. to the left of the median line, the right border 4.5 cm. from the median line, the long diameter 14.5 cm., the diameter at the base 9.3 cm., the diameter of the great vessel 8.8 cm. and the diameter of the chest 23.5 cm. Within the last year he has had a punch operation for prostatic obstruction and he has hardly recovered from the effects of this. He came to me recently because of swelling of the ankles and because he felt so "all in." His pulse rate was 80. His blood pressure was 240/20 at the first visit and since then has been 200/20. There has been no recurrence of the swelling of the ankles. His urine is loaded with pus and has a large trace of albumin with occasional casts. At present I am treating the bladder condition and my question is whether I should also give him bismuth injections. Please omit name.

M.D., Massachusetts.

ANSWER.—It would not seem advisable to treat this patient for syphilis, provided further examination of the heart does not reveal evidence of syphilitic aortic disease. A weekly positive Wassermann reaction in a man 68 years old, with hypertension, nephritis and prostatic enlargement, is of no significance in view of the fact that he has no clinical signs of active syphilis. The older teaching offered syphilis as one of the causes of hypertension; however, no concrete relationship between syphilis and hypertension has ever been established. The enlarged heart is probably a manifestation of hypertension. The prostatic disease has no relationship to the syphilis. Accordingly, to add a further load in the form of antisyphilitic treatment to an already damaged kidney and vascular system would not seem advisable. This objection to further treatment in this case is augmented by the fact that the antisyphilitic treatment would not be of any material help to either the nephritis or the vascular disease in this patient. The positive Wassermann reaction is probably the least of the patient's troubles and hence might well be ignored.

#### DYSMENORRHEA AT ALTERNATE MENSTRUAL PERIODS

To the Editor:—A woman, aged 22, single, and in good health otherwise, has for five years (approximately) had severe pain in the right lower quadrant of the abdomen with alternate menses. The alternating menses are pain free but these periods (every other one) produce severe pain in the abdomen as stated. The pain begins shortly (a few hours) before the onset of bleeding and lasts through the period and slightly or after it is over (few hours). Accompanying these painful periods there is a loss of typical endometrial tissue by the vagina, which lasts through the period of bleeding. The patient is a nurse and she states that this material looks just like the scrapings she used to see in surgery following curettages. The alternating periods (those that are pain free) have no such discharge of tissue. All the periods last from four to five days with average bleeding. Bimanual examination is negative. The cervix looks excellent. The canal seems very open. General examination otherwise is negative. The pain is getting worse of late, so that the patient cannot work when it is present. I would appreciate any ideas as to diagnosis and as to what can be done here to relieve her. Kindly omit name.

M.D., Chicago.

ANSWER.—This history is not typical of any single gynecologic disorder. Endometriosis should cause dysmenorrhea with each menstrual period and would not produce an evacuation of tissue-like material from the uterus. The same is true of adenomyosis uteri. Membranous dysmenorrhea is accompanied by the expulsion of tissue with every period. If ovulation occurs alternately in the ovaries of this patient, one might possibly explain the right-sided pain at intervals of eight weeks, but ovulation pain (mittelschmerz) would appear two weeks before, not during, the menses. The possibility of frequent abortion appears to be ruled out. In ectopic pregnancy a decidual cast is extruded but once. A polyp would hardly be evacuated piecemeal. No history of foreign body in the uterus is suggested. To summarize: The dysmenorrhea could be due to efforts of the uterus to expel something within its cavity (foreign body, polyp, myoma, gestational products, endometrial membrane); it could be due to endometriosis, to pelvic inflammation or to functional disorders. The tissue could be the membrane of membranous dysmenorrhea, gestational products

recover the amounts due for the use and benefit of the creditors. If the defendant owed the drug store, the nurses, the hospital and the other physicians, these creditors had a cause of action against him to recover the amounts due. But in the absence of any special assignment of those claims to the plaintiffs, and without some special authorization to bring this suit on behalf of the creditors, the plaintiffs were without interest and had no cause of action. The court held, therefore, that the plaintiffs' suit for these amounts should have been dismissed.—*Toler & Toler v. Munson (La.)*, 168 So. 93.

**Malpractice: Osteomyelitis Following Tooth Extraction.**—One of the plaintiffs, a child aged 9, was brought to the office of the defendant, a dentist, suffering from a toothache. The gum around the aching tooth was, as described by the mother of the child, "flaming red." The defendant injected an anesthetic into the gum on each side of the tooth and extracted the tooth. The boy's face later became swollen and he suffered great pain. The following day the defendant suggested that a physician be consulted, and the boy's condition was diagnosed as osteomyelitis, which necessitated hospitalization for a period of five months. Attributing the illness to the negligence of the defendant, the boy, by his next friend, and the father sued the defendant. The trial court gave judgment for the plaintiffs and the defendant appealed to the supreme court of New Jersey, contending that the lower court erred in refusing to direct a verdict for him.

The plaintiffs charged that the osteomyelitis was caused by the defendant's using the infiltration method to cause loss of sensation, which by the injection of a needle into the infected area permitted the infection to spread. The defendant should have, according to the plaintiffs' contention, injected the anesthetic outside the infected area. Whether or not the defendant used that standard of care which the law required of him, said the supreme court, was a matter for expert testimony. An expert witness, a dentist, testified that the defendant did not use the "kind of anesthetic" suitable for the condition in question and did not exercise the skill that is ordinarily used by members of his profession in cases of this character. Other dental expert witnesses for the plaintiff corroborated this testimony, stating that it was bad practice and contrary to that of the ordinary skilful dentist to inject anesthetics into an infected area. The defendant himself admitted that an anesthesia by infiltration would not have been proper in the present case but contended that he used the approved "mandibular (conductive) method." Other witnesses testified that the defendant used and exercised the skill that is required and ordinarily possessed by others in his profession in his treatment of the boy, and that even if the infiltration method was used, it would be in keeping with proper practice in a great many instances. Thus, said the court, there was a conflict in the testimony of the witnesses that presented an issue for the determination of the jury. The trial court was therefore justified in denying the defendant's motion for a directed verdict. The judgment of the trial court was affirmed.—*Zulinsky v. Greenblat (N. J.)*, 184 A. 806.

#### Autopsies: Exhumation of Body Demanded by Insurer.

—The defendant insurance company issued to the insured an accident policy which provided that the company "shall have the right and opportunity to examine the person of the insured when and so often as it may reasonably require during the pendency of claim hereunder, and also the right and opportunity to make an autopsy in case of death where it is not forbidden by law." The insured died from a gunshot wound under circumstances indicating either accidental or suicidal death. The company's local agent and its adjuster learned of the death the day after it occurred. A coroner's inquest was held but no autopsy was performed because the coroner, a physician, saw, as he subsequently testified, by his external examination all that could be discovered by autopsy. The insurance adjuster was present at the inquest but made no demand for an autopsy. About five weeks later, however, the company demanded an autopsy, which demand was refused by the insured's widow, a beneficiary under the policy. The company thereupon denied liability under the policy. In a suit against the company that followed, the trial court gave judgment for the beneficiaries, and the company appealed to the United States circuit court of appeals, fifth circuit.

The evidence in this case, said the circuit court of appeals, strongly negatived the inference that death was of a suicidal nature and the trial court properly submitted that question to the jury under correct instructions. With respect to the autopsy clause, the policy did not provide that if an autopsy was denied benefits were to be forfeited, nor did it obligate the beneficiary to take the initiative in having a postmortem examination made. A fair interpretation of the clause, the court said, is that the insurer shall be permitted, by the consent of those entitled to give it, to have an autopsy performed, or, if consent is withheld, to appeal to a court to decide on the propriety of it. Incidentally, the court said, the right to examine the person of the insured, as provided in the first part of the excerpt quoted, if applicable after death, did not cover the right to mutilate by dissection such as is involved in an autopsy. Strictly speaking, the court continued, there is no property in a corpse. The right to possess, preserve and bury it, however, belongs, in the absence of testamentary direction, to the surviving spouse, if there is one, and, if not, to the next of kin, who may maintain an action for a deprivation of the right of sepulture or a mutilation of the body. A body once suitably buried ought to remain undisturbed except for necessity or laudable reasons. In the present case the adjuster of the company examined the scene of the tragedy and attended the inquest but, so far as the record shows, did not bring the matter to the attention of the company. Five weeks later he, at the instance of the company, demanded that the body be exhumed to permit an autopsy by the coroner, who testified that nothing more could be learned by an autopsy. Under such facts, it was neither reasonable to exhume the body nor necessary in order to obtain probably important evidence. The judgment against the company was consequently affirmed.—*Travelers Ins. Co. v. Welch*, 82 F. (2d) 799.

## Society Proceedings

### COMING MEETINGS

- Alabama, Medical Association of the State of, Birmingham, April 20-22. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.
- American Association for the Study of Neoplastic Diseases, Philadelphia, April 9-10. Dr. E. R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Anatomists, Toronto, Ont., March 25-27. Dr. George W. Corner, 260 Crittenden Blvd., Rochester, N. Y., Secretary.
- American Association of Pathologists and Bacteriologists, Chicago, March 25-26. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.
- American College of Physicians, St. Louis, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia, Executive Secretary.
- American Pediatric Society, University, Va., April 29-May 1. Dr. Hugh McCulloch, 325 North Euclid Ave., St. Louis, Secretary.
- American Physiological Society, Memphis, Tenn., April 21-24. Dr. A. C. Ivy, 303 East Chicago Ave., Chicago, Secretary.
- American Society for Experimental Pathology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- American Society for Pharmacology and Experimental Therapeutics, Memphis, Tenn., April 21-24. Dr. E. M. K. Gelling, 947 East 58th St., Chicago, Secretary.
- American Society of Biological Chemistry, Memphis, Tenn., April 21-24. Dr. H. A. Mattill, Chemistry Building, State University of Iowa, Iowa City, Secretary.
- Arizona State Medical Association, Yuma, April 1-3. Dr. D. F. Harbridge, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 12-14. Dr. W. R. Brooks, 602 Garrison Ave., Ft. Smith, Secretary.
- Federation of American Societies for Experimental Biology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- Florida Medical Association, St. Petersburg, April 5-7. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Hawaii Territorial Medical Association, Hilo, April 30-May 2. Dr. Douglas B. Bell, Queen's Hospital, Honolulu, Secretary.
- Louisiana State Medical Society, Monroe, April 26-28. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, April 27-28. Dr. Walter Dent Wise, 1211 Cathedral St., Baltimore, Secretary.
- New Jersey, Medical Society of, Atlantic City, April 27-29. Dr. J. B. Morrison, 66 Milford Ave., Newark, Secretary.
- Ohio State Medical Association, Dayton, April 28-29. Mr. C. S. Nelson, 79 East State St., Columbus, Executive Secretary.
- South Carolina Medical Association, Columbia, April 13-15. Dr. E. A. Hines, Seneca, Secretary.
- Southeastern Surgical Congress, Charlotte, N. C., March 8-10. Dr. Benjamin T. Beasley, 45 Edgewood Ave., S.E., Atlanta, Ga., Secretary.
- Tennessee State Medical Association, Knoxville, April 13-15. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.
- Western Branch of American Public Health Association, Phoenix, Ariz., April 13-15. Dr. William P. Shepard, 600 Stockton St., San Francisco, Secretary.

# PERSISTENT UTERINE BLEEDING

*To the Editor:*—A woman, aged 22, 5 feet 8 inches (173 cm.) tall, weighing 183 pounds (83 Kg.), well developed, started to menstruate at the age of 10 and continued regularly until three years ago, at which time she began and has continued to menstruate almost continuously ever since. Sometimes it clears up for a few days, then starts again, mostly small amounts but at other times quite free. She is a virgin and seems to be in good health otherwise. The blood pressure, heart and kidneys are normal. The breasts are larger than normal. She has no pain, and no tumors can be made out. I gave her extract of placenta, mammary and thymus gland in combination and for six weeks everything was all right, but since that time the condition has been as bad as ever. Can you give me anything that might help her? I believe it to be merely a glandular case. Please omit name. M.D., Pennsylvania.

**ANSWER.**—Granted that palpation reveals no pelvic abnormality, curettage sometimes relieves persistent bleeding, but usually not for more than two or three months except in cases in which a polypoid tumor is found.

The basal metabolic rate should be determined. Thyroid therapy is almost specific in many cases in which the metabolism is low and is indicated in all cases unless the rate is high.

Calcium lactate, 2 Gm. in a single dose, once daily, should be given even though the blood calcium level is normal.

Deranged metabolism may be helped by one or two vitamin capsules daily.

Blood transfusion is helpful and would be indicated as a routine measure in these cases were it not an expensive therapeutic measure and accomplished with considerable effort.

This is evidently an endocrine case and may resist all efforts at control, other than ray therapy or hysterectomy. If not well beyond 40 years of age, removal of the body of the uterus is preferable to irradiation.

# TECHNIC OF STERILIZATION OF INSTRUMENTS

*To the Editor:*—What is at present considered safe technic for sterilization of non-spore formers and of spore formers on sharp steel instruments with "germicides" and on boilable instruments? Is steam autoclaving of corrodible material, immersed in oil, a safe procedure?

DELL T. LUNDQUIST, M.D., Palo Alto, Calif.

**ANSWER.**—Sterilization of surgical instruments (dull or sharp) can be accomplished by boiling such instruments in a 2 per cent soda (sodium carbonate) solution followed by rinsing in sterile water. The soda will saponify the oily coating of hinged instruments and allow the steam to penetrate. The alkalinity of the soda water will also prevent corrosion. Earth spore-bearers are not killed in a period of two hours' boiling (1 Gm. of soil per liter of water) but when 0.1 Gm. is used the water becomes sterile at the end of one hour and fifteen minutes.

Oiled instruments cannot be autoclaved, since moisture cannot penetrate an oily layer. It is moist heat that kills bacteria and their spores. However, a hot air oven and temperatures of from 170 to 180 C. (338 to 356 F.) for about one hour will sterilize oiled and corrodible material. The use of a liquid petrolatum bath is fraught with danger in an operating room since a temperature of from 170 to 175 C. (338 to 347 F.) for a period of at least fifteen minutes is required to insure sterilization.

Chemical methods of sterilization of sharp instruments vary and the majority, like alcohol, are ineffective. Some of the most modern mercurials in tincture form may be employed, provided the instruments are left in such tinctures for a considerable period. Mercury bichloride will eventually attack metal.

# LEFT-HANDEDNESS

*To the Editor:*—Please discuss the treatment of an 8 year old boy who is a "true sinister"—left handed, left footed, a mirror writer and inclined to stutter and suffer from persistent enuresis. Please omit name.

M.D., Ontario.

**ANSWER.**—Effort should be directed toward established use to the left hand. The tendency to reversal in writing warrants study to determine whether this does not accompany reversal of images that would be confusing in the boy's efforts to learn to read. If this is established, phonetic and kinesthetic methods such as used with children with "word blindness" or reading disabilities should be used in teaching him to read. This will tend to overcome also the mirror writing. Unless the stuttering and enuresis are quite severe, it would probably not be wise to attack these problems directly, since they doubtless are dependent on the muscular incoordinations that attend confusions in handedness. Their subsidence is more likely to result from a general stabilization of the boy's activities, the reduction of tension and strain. Such a problem should be referred for

study to a psychiatrist or child guidance center, since treatment involves general management of the child's program of activities. See "For Stutterers," by Smiley Blanton and M. G. Blanton, New York, D. Appleton-Century Company, 1936.

# KERATOCONUS

*To the Editor:*—Have you any information regarding the relation of vitamins to keratoconus? The relation of thyroid to keratoconus? Any therapeutic means that has any effect on keratoconus?

WENDELL L. HUGHES, M.D., Hempstead, Long Island, N. Y.

**ANSWER.**—As the cause of keratoconus is still unknown, the relationship of the vitamins or of any of the products of the glands of internal secretion to the corneal condition is a mystery. In many of the cases there appears to be a marked hereditary tendency, as van der Hoeve has so aptly pointed out and illustrated with family trees of as high as five generations. In other cases hypothyroidism has been found and the corneal process apparently arrested by proper therapeutic measures (see E. von Hippel, Schnaudigl, Siegrist, Török and Redway); but the empirical use of the glandular extracts is definitely contraindicated. Meyer Wiener advocated the use of 1:1,000 epinephrine, and in a few instances the use of such drops three times daily has arrested the progress of the keratoconus. In the majority of cases the condition is more or less self limited and ceases to advance at about the age of 40 years. For some unexplainable reason, the constant use of contact glasses, when they can be worn constantly, seems to arrest the condition.

# USE OF GULLSTRAND OPHTHALMOSCOPE

*To the Editor:*—Can you inform me whether the Zeiss Gullstrand ophthalmoscope is practical, easy to operate; and the best binocular ophthalmoscope? What is the date of the latest model? Who handles it in this country?

L. J. DESWARTS, M.D., Greensburg, Ind.

**ANSWER.**—The Gullstrand ophthalmoscope is an investigative instrument and not for routine practice. The large models are made by Zeiss of Germany and by Bausch and Lomb of the United States and are both about fifteen years old. Bausch and Lomb has recently brought out a simplified smaller Gullstrand ophthalmoscope that is easier to handle but lacks some of the advantages of the large models. The Zeiss model is handled by Carl Zeiss of 485 Fifth Avenue, New York, and the Bausch and Lomb by the Bausch and Lomb Optical Company, Rochester, N. Y.

# HEMORRHAGE INTO JOINTS IN HEMOPHILIA

*To the Editor:*—A young man with hemophilia has frequent recurring hemorrhages into the various large joints. To control his pains during these attacks requires morphine. He now has the habit. What substitute could be used to take its place? Kindly omit name and address.

M.D., North Dakota.

**ANSWER.**—The use of capsules of acetylsalicylic acid (0.3 Gm.) fortified by combination with phenobarbital (0.05 Gm.) and possibly with extract of hyoscyamus (0.02 Gm.) is likely to relieve the pain. If not, the addition of codeine phosphate (0.05 Gm.) would still further increase the analgesic power of the combination, while being less objectionable than morphine.

# TESTS OF VISION IN CIVIL SERVICE

*To the Editor:*—May I request detailed information regarding the methods of determining certain abilities in vision for applicants of the United States Civil Service Commission examinations? Kindly give me the normals also for these requirements. I am enclosing the physical fitness form 13 and marking the sections concerned. Please omit name.

M.D., New York.

**ANSWER.**—The specifications for normal of distance vision are clear as enumerated in form 13. The normal is 20/20. The near test used in this form (4 point type, in which the size of the letter is 0.6985 mm.) is clearly stated. The longest and shortest distance from the eye at which the question can be read will vary with the accommodation of the applicant. The older the individual, the shorter the range. Refer to Duane's chapter on Accommodation in the eighth edition of the Duane-Fuchs textbook.

# DIPHTHERIA IMMUNIZATION

*To the Editor:*—I am a physician, aged 33, in good health. My Schick test which I took recently is positive (markedly so). Eight years ago it was negative. What procedure as to immunization should I adopt? What material should I use? Kindly state dosage and frequency of administration. Please omit name.

M.D., Illinois.

**ANSWER.**—Immunization may be carried out in the usual manner with diphtheria toxoid solution.

blasts which are laid down in the form of a nodule. About the periphery of these nodules in each case there is a zone of lymphocytes. The elements of the tissue reaction to the tubercle bacillus and to silica are essentially identical and the resultant lesions are similar. The simple inorganic substance silicon dioxide is capable of exciting every tissue response that can be produced by the complex living organism *Mycobacterium tuberculosis*. The reaction to the latter is more uniform because its constitution is more or less constant and it soon establishes a limited equilibrium with the tissues of the host. The reaction to silica is largely determined by the number and the size of the particles that come to rest within a given focus in the body. Both irritants cause varying degrees of proliferation, exudation and necrosis, resulting in a nodular type of reaction. In speculating on the causes of this similarity it would seem that both irritants are relatively insoluble but that perhaps both of them continually liberate minute amounts of irritating substances. Both irritants react on the mononuclear phagocyte to alter its internal structure in a similar manner, injuring mononuclear phagocytes so that multinucleated giant cells are produced. The nodular character of the lesions in both silicosis and tuberculosis is also probably dependent on altered behavior of the mononuclear phagocyte. In each case this cell is responsible for the concentration and the walling off of the irritant in a localized focus. The study confirms the specificity of the tuberculin reaction and again demonstrates that the mere presence of a pseudotubercle composed of epithelioid cells does not create hypersensitiveness to tuberculin. Silica itself is not antigenic, and intracutaneous injections produce the same effects in silicotic and in normal control animals.

### Dementia Paralytica Treated by Mosquito Inoculation.

—Since January 1934 the treatment of dementia paralytica at the Manhattan State Hospital by means of induced malaria has been carried out entirely by mosquito inoculation. Up to March 1936 Kusch and his collaborators treated seventy-two patients. The mosquitoes used were infected with the McCoy strain of *Plasmodium vivax*. After the incubation period of from eight to eighteen days (usually on the eleventh to the fourteenth day) there was an acute rise in temperature to about 104 F. followed by daily paroxysms and remissions. Chills most frequently started from one to four days after the onset of the high temperature. Following the acute rise in temperature there was usually a quotidian fever, the temperature increasing daily to a peak of from 104 to 106 F. about the third to the fifth day. Less frequently the tertian or mixed type of fever was encountered. This peak was reached daily until near the end of the course, when there commonly occurred a gradual decline for a few days, after which the temperature returned to normal and remained there. Quinine, 30 grains (2 Gm.), was administered daily for seven days, after spontaneous cessation of symptoms. It was given during the course

of the fever only if symptoms of extreme severity, such as marked weakness, threatening general collapse or definite jaundice, occurred. As to the duration of the attack, this series averaged twenty-two paroxysms. A comparison of the clinical results obtained in patients inoculated with malaria by mosquito bite and those inoculated with blood shows that the main clinical difference between the two groups was a less severe malaria in the mosquito-inoculated group, permitting a longer course of malaria treatment. Final analysis showed a "remission" rate of 26.4 per cent and "improved" rate of 48.6 per cent in the mosquito-inoculated group, while the comparable rates for the blood-inoculated group were 19.3 and 35.8 per cent, respectively.

**Ruptures of Muscles and Tendons.**—Conwell and Alldredge declare that ruptures and tears of muscles and tendons may be seen in any age group. They may result from direct or indirect trauma, but the certain predisposing factors are senility, pathologic changes (arthritis, myositis, acute infectious disease, arteriosclerosis, syphilis, tuberculosis and neoplasm), physiologic predisposition, occupation, fatigue and trauma. Early diagnosis in these cases prevents unnecessarily prolonged treatment and in many instances a permanent disability. While physical examinations in making a diagnosis of a ruptured or torn muscle or tendon are relied on mainly, the authors have been aided in certain instances by using a roentgen technic which brings out the soft structures. The procedure is limited and can be applied only to the larger tendons and muscles. If all the so-called sprains and bruises and other injuries could be exposed at operation, it is possible that many other muscles than those usually reported would be found to be the site of either partial or complete rupture. Illustrative cases of ruptures of the biceps brachii, quadriceps muscles and tendon, patellar tendon, calf muscles, achilles tendon and hernia of muscles are presented. Complete ruptures should usually be treated operatively and sutured, while partial ruptures may usually be treated by immobilization. The treatment, however, in any case must be individualized.

**Organic Calcium in Healing of Fractures.**—Downs experimented with organic calcium phosphate (hexacalcium-inositol hexaphosphate) on the healing of fractures. A total of 896 rats were used whose average age was 71 days. The experiment was divided into four separate phases: weight gains of animals, blood chemistry, breaking-strength tests and histologic studies. The evidence drawn from each phase of the present study indicates that an organic form of calcium phosphate is metabolized more readily than is the case for any of the inorganic forms generally used for such work. While a great variance in the results was not obtained by the feeding of two types of organic calcium salt, it was also apparent that that obtained from cereal (Indian corn) was utilized more readily by the organism than that from milk. Satisfactory evidence was obtained to support these conclusions from the weight gains of animals throughout the course of the experiments, from the breaking-strength tests and from histologic studies. Blood chemistry studies were otherwise negative, but the more rapid clotting of the blood of the animals fed with calcephos indicates the value of further work in this direction.

## Book Notices

**An Introduction to Materia Medica and Pharmacology.** By Hugh Alister McGulgan, Ph.D., M.D., Professor of Materia Medica, Pharmacology and Therapeutics, University of Illinois College of Medicine, Chicago, and Edith P. Brodie, A.B., R.N. Cloth. Price, \$3. Pp. 580, with 89 illustrations. St. Louis: C. V. Mosby Company, 1936.

Dr. McGulgan in revising the previous edition of Brodie's *Materia Medica for Nurses* has made considerable change in the subject matter and has brought the book strictly in accord with the new Pharmacopeia and National Formulary. These two standards are used as a basis for the discussion of the preparations. Frequent reference is also made to *Useful Drugs, New and Nonofficial Remedies* and the *Handbook of Therapy*, so that the importance of evaluating both the official and the more recently introduced therapeutic agents is stressed. The general plan of the text is an excellent one; the first part deals with elementary materia medica and the second with advanced materia medica and therapeutics. Each chapter is followed by an extensive list of pertinent questions for reviewing the subject and a rather well selected bibliography for collateral reading. The author stresses the importance of pharmacologic experimentation as a forerunner of clinical administration of drugs and has included the details of pharmacologic studies of many of the drugs. The sections dealing with weights, measures, equivalents, calculations of dosages and strengths of solution are preceded by an arithmetical review which should leave little excuse for failure to master these important subjects. Vitamin F is designated as the American, and B<sub>1</sub> the English, name for the antineuritic factor, whereas common usage has failed to adopt F to indicate this dietary essential and B<sub>1</sub> is the more common term here as well as abroad. The usefulness of yeast seems to have been overstated, since it is described not only as a laxative and a source of vitamin B but also as a curative agent in furunculosis, boils and pimples. On the whole the book should prove satisfactory for the purpose intended, since it is one of the better textbooks especially prepared for nurses and McGulgan's revision has greatly extended its practical value.

**Étude critique des techniques opératoires de la sinusite fronto-ethmoïdale purulente chronique. Nouvelle méthode d'évidement fronto-ethmoïdal.** Par le Docteur Louis Ledoux. No. 28, Monographies otorhino-laryngologiques internationales. Fondées par M. Vernet. Publiées par le Professeur G. Portmann, H. Aloin, L. Ledoux, M. Sourdille et M. Vernet. Analyses en allemand, anglais, espagnol et italien. Paper. Price, 25 francs. Pp. 216, with 42 illustrations. Bordeaux: Editions Delmas, 1936.

This brochure is one of a series of international otorhino-laryngologic monographs. In the introduction, Ledoux calls attention to the various types of fronto-ethmoid operations usually practiced. Then follows a chapter on the anatomy of the frontal sinus and the structures in its vicinity. The author discusses only the chronic purulent conditions involving the frontal sinuses and ethmoid cells. In cases in which there is also a chronic maxillary sinusitis, he advises the use of the Luc-Caldwell operation. In order to facilitate healing, an attempt is made to produce a new mucous membrane lining derived from the underlying layer of connective tissue, together with surface epithelium by the extension of the epithelium of neighboring areas. The author insists that any operative procedure which is supposed to produce a radical cure must show a maximum of efficiency due to perfect curettage and maximum drainage with permanent and accessible approach, together with a minimum of destruction. In connection with the latter, first there should be a preservation of the supra-orbital ridge, the anterior wall of the frontal sinus, and a limitation of the skin incision to the eyebrow. The operative technic is described in detail, and the various stages are beautifully demonstrated by a considerable number of illustrations. The first operation, under local anesthesia, consists in the opening of the cells of the nasal process of the superior maxilla, which facilitates the curettage of the ethmoid cells and gives easy access to the frontal sinuses. The second operative procedure, also under local anesthesia, consists in an incision of the skin through the eyebrow, the incision of the periosteum covering the area of bone to be removed, and lastly the removal of the bone and the formation of a trough from 1 to 1.5 cm. in width, depending on the size of the frontal sinus. The author uses a bone drill

and a Gigli saw for the removal of the frontomaxillary process. He avoids the use of gouges and mallet and uses a punch forceps instead. In the postoperative treatment, irrigation through the supra-orbital region is used for about fifteen days if only the anterior ethmoid cells are involved, but if the posterior ethmoidal cells and sphenoidal cells are also affected, this must continue for several weeks or even months. The patient, after leaving the hospital, irrigates the wound himself but is seen every third day, and irrigations are done by the surgeon with 3 per cent chromic acid solution to control excessive granulations and to permit epithelization. At the end of the little volume are abstracts of the methods employed, written in Italian, Spanish, English and German. This monograph has its subject systematically presented with excellent drawings to illustrate the various stages of the operation.

**Toxicology or the Effects of Poisons.** By the late Frank P. Underhill, Ph.D. Thoroughly revised by Theodore Koppányi, Ph.D., Professor of Pharmacology and Materia Medica, Georgetown University School of Medicine. Third edition. Cloth. Price, \$2.50. Pp. 325. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

The increasing prominence of chemistry in modern life has made toxicology a matter of everyday concern. Hardly any occupation is devoid of contact with toxic materials; even the air one breathes and the food one eats is suspect. The former is often laden with smoke containing carcinogenic and other toxic agents as well as industrial dusts; the latter may be contaminated with lead and arsenic compounds used as insecticides. Many new compounds known or suspected to be harmful are introduced every day into industry, and new industrial methods increase the contact of workers with known poisons. Toxic gases are being used in industrial disputes as well as in warfare. The recent discovery of the toxic potentialities of certain drugs such as aminopyrine and cinchophen, the introduction of new and potentially dangerous anesthetic agents, the preparation and marketing of an endless series of barbituric acid derivatives, the widespread and immoderate use of tobacco, and the use of tetra-ethyl lead in gasoline with the resultant discharge into the atmosphere in both city and country of lead compounds in the exhaust of internal combustion engines emphasize the growing, in fact urgent, importance of toxicology. Satisfactory works on this subject are rare indeed. It is therefore a significant event that Underhill's well known book has now been brought abreast of the times by Koppányi after a lapse of eight years. This volume contains material on most of the common poisons. Its brevity makes it particularly useful for students; the book is less useful for reference because of the brief treatment accorded most of the subjects and the necessary omission of many toxic compounds employed in industry. Substances added to this edition include avertin (tribrom-ethanol), camphor substitutes, cinchophen, cyclopropane, dinitrophenol, ephedrine, mercurial diuretics, newer barbituric acid derivatives, quinine and its substitutes, triorthocresyl phosphate and thyroid. A number of subjects are treated by the authors on which there has been considerable controversy, as, for instance, the toxicology of aluminum compounds, a subject to which Underhill made notable contributions. In regard to the equally controversial but more urgent question of the widespread use of ethyl gasoline the authors state that "general knowledge of the action of inspired dust particles containing lead compounds would seem to indicate that the spraying of lead compounds by the exhausts of automobiles constitutes a distinct menace."

**Hudtemperaturernes Betydning for Varmerafgiften hos Mennesket og Forsøg paa at beregne Varmerafgiften paa Grundlag af Hudtemperatur.** Af Sven Ulrich. Paper. Pp. 123, with 12 illustrations. Aarhus: Universitetsforlaget; Copenhagen: C. A. Reitzels Forlag, 1934.

The first three chapters of this monograph contain a discussion of the various factors involved in the loss of heat from the body: loss by radiation, conduction, convection and evaporation. The loss by evaporation the author assumes to be one fourth of the total heat loss. The conditions governing the loss of heat by evaporation from the skin the author studied by means of a specially constructed apparatus consisting in the main of a metal box heated by an electric bulb and covered with wet felt. The heat production of the bulb was known, the loss of water by evaporation measured by weighing. It was found that the evaporation was chiefly a function of the heat production. Variations of air temperature from 20.5 to

down along the right jugular bulb and then posteriorly in the neck to connect with diffuse bilateral posterior deep cervical abscesses. This condition, with the anterior cervical spaces free from infection, is unique. The perfectly healed right mastoid wound and dry cavity of the middle ear, with all the pain, nasal obstruction and sinus infection through the earlier stages on the left side, presented a confusing symptom complex. The development of recurrent asthma with the onset of infection of the sphenoid suggests that previous disease of the sphenoid may have escaped notice and that its reactivation due to lowering of the patient's resistance by the mastoid infection caused the unusual symptoms and overwhelming infection which followed. Osteomyelitis of the sphenoid bone will not respond to drainage by steel drills. It requires extensive surgical removal of bone beyond infected thrombosed blood vessels as in other locations. This is not possible by any present day technic.

**Observations on Larynx in Tuberculous.**—Schuster studied the larynx in 452 cases of pulmonary tuberculosis with subjective symptoms referable to the ear, nose or throat. Tuberculous laryngitis was present in 19.2 per cent of the cases. This incidence is somewhat higher than would be expected in the mere routine examination of the larynges of tuberculous patients, without subjective complaints. Diseases of the nose and throat were no more frequent in patients with tuberculous laryngitis than in those in whom the disease was limited to the lungs. The pathologic picture is essentially that of tuberculosis elsewhere and is extremely protean, more than one type of lesion occurring in the same larynx and frequently complicating secondary nontuberculous lesions. Subjective symptoms are of little diagnostic value, and the diagnosis is based on the gross observations in the larynx, with the confirmatory observations in the chest and results of laboratory and roentgen study. Prognosis is good as to healing of the laryngeal lesion in the early stages but guarded as to ultimate recovery. Early treatment is based on cooperation with the specialist in diseases of the lungs in the general care, on absolute rest of the voice, on pulmonary collapse in suitable cases and on avoiding overtreatment locally. Occasionally, reflected sunlight is of value in supervised cases. When the lesion is progressive, the radical and repeated use of the galvanocautery is of great worth, care always being taken not to exhaust the patient at any one sitting. Time and temporary relief may be gained by blocking the superior laryngeal nerve. Early use of the actual cautery is urged, especially when the condition does not promptly respond to conservative treatment. Pulmonary tuberculosis is basically the primary focus of laryngeal tuberculosis. Intelligent cooperation between the "phthisician" and the laryngologist will result in striking results in the prevention, early diagnosis and successful treatment of this serious complication.

**Curability of Carcinoma of Stomach.**—Hunt believes that the present status of operability of carcinoma of the stomach is that in about 50 per cent of the patients the disease is clinically

inoperable at the time the diagnosis is established. Clinical inoperability in these cases may be manifested by ascites, fixation of a large palpable mass, jaundice or definitely palpable metastatic involvement. Carcinoma in its various situations in the stomach differs greatly in its clinical manifestations and in its curability. As there is no clinical syndrome by which early carcinoma of the stomach may be recognized, competent roentgen investigation of the gastro-intestinal tract will reveal early operable carcinoma more frequently than heretofore and will materially enhance the possibility of cure. Once the diagnosis of carcinoma has been established and no clinical evidence of remote or metastatic extension of the disease is discernible, surgical exploration promptly becomes urgent. Progress in the curability of carcinoma of the stomach will not occur through extending the limits of operability and the execution of more radical surgical procedures for extensive disease. However, opportunity does exist for enhancing the curability of this disease through submitting the patient to the highly perfected procedure of semiradical partial gastrectomy, with its alternative methods of establishing gastro-intestinal continuity early after the inception of the disease when it is still closely confined as an intragastric lesion. For improvement in the present outlook in carcinoma of the stomach the patient is not dependent as much on the surgeon as on the physician from whom he first seeks counsel.

**Embolism and Thrombosis of Larger Arteries.**—Graham warns that early diagnosis is of first importance in the treatment of acute arterial occlusion. The symptoms and signs are characteristic. As soon as a diagnosis is made, the patient should receive an intravenous injection of one-half grain (0.032 Gm.) of papaverine hydrochloride and be transferred to a hospital for more complete investigation and further treatment. If arterial thrombosis is present, the patient should be given an intensive course of treatment by alternate suction and pressure. Between treatments the limb should be kept under an electric cradle at a temperature of from 95 to 104 F. Further injections of papaverine should be given every six hours during the first three or four days. If the response to treatment is not satisfactory and amputation becomes necessary, it can usually be done at a lower level and healing of the stump is more prompt as a result of the preliminary treatment. In cases of embolic occlusion affecting the lower extremities, the same plan of treatment should be followed or, if the patient is seen early, embolectomy may be considered. In view of the better development of the collateral circulation in occlusion of the upper as compared with the lower extremity and the natural tendency toward recovery of the peripheral circulation, the injection of papaverine and the local application of heat are probably the only methods of treatment necessary for embolic occlusions of the upper extremity.

**Management of Arthritis.**—The patients (twenty-seven) referred to were entirely unselected, being one group appearing in Farley's private practice and remaining under treatment sufficiently long to make valid data for a report. Some of this group were treated for the first time, while others had received treatment elsewhere over periods as long as five or six years. The entire group was given high vitamin D therapy. The preparation used is a capsule containing 50,000 or 100,000 U. S. P. units (international units) of vitamin D. The initial dosage was usually 200,000 units daily. This dosage was increased in obstinate cases to from 300,000 to 600,000 units

rial is covered by a group of thirty-eight scientists from the United States, England, France, Sweden, Germany, Hawaii, The Netherlands and the Soviet Union. As in previous volumes, an excellent author index is included but no subject index. It is hoped that the publishers will not only issue a collective index for the first five volumes but include subject indexes in future volumes. The latter will greatly enhance the utility of these excellent reviews.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

#### Malpractice: Invasion of Patient's Right of Privacy.

—The appellant, a physician, permitted the district manager of a surgical supply house, a layman, to cauterize a small growth in the cervix of a patient who applied to the physician for relief from a vaginal discharge. The services of the layman were utilized because the physician had not familiarized herself with a new "cauterizing machine" apparently purchased from the surgical supply house. Attributing certain conditions that followed the cauterization to the physician's negligence, the patient brought suit alleging, among other things, that the physician did "negligently, carelessly, and recklessly cut, burn and otherwise injure the plaintiff," and "disregarding her duty to the plaintiff . . . sought, requested and allowed . . . a person untrained in the science of medicine or surgery" to "see and view the body and private person of the plaintiff" and to perform the operation. The trial court gave judgment for the patient, and the physician appealed to the Court of Appeals for the District of Columbia. Before the appeal was heard, the patient committed suicide and the administrators of her estate were substituted as appellees.

A physician in practicing his profession, said the court, must exercise the ordinary care and skill of that profession in a similar locality, giving due consideration to modern advancement and learning. A patient who seeks to recover damages against a physician, alleging lack of skill or negligence, has the burden of proving the averments. "Before the plaintiff can recover, she must show by affirmative evidence—first, that defendant was unskilful or negligent; and, second, that his want of skill or care caused injury to the plaintiff. If either element is lacking in her proof, she has presented no case for the consideration of the jury." *Ewing v. Goode* (C. C.) 78 F. 442. Generally speaking, the failure of an operation creates no presumption of lack of skill and care. It is a circumstance, however, entitled to some consideration in connection with other evidence tending to prove lack of skill or care. The evidence in the present case, continued the court, disclosed that the patient at the time of the cauterization was and had been suffering from a chronic genital condition for which she had previously been treated. The "cauterizing machine" was of an approved type. A physician who treated the patient both before and after the time of the cauterization testified that he found no evidence of injury by reason of the cauterization done by the layman. Another medical witness who had treated the patient subsequent to the cauterization testified "that he found nothing . . . that was unusual from that following the ordinary cauterization." The case of *DeMay v. Roberts*, 46 Mich. 160, 9 N. W. 146, in which damages were awarded against a physician, was, in the opinion of the court, not in point. In that case an action in deceit was brought against a physician who took a layman with him to attend a confinement case when there was no emergency requiring the layman's presence. The present case, said the court, was tried and submitted to the jury on the theory of injury to the patient resulting from the physician's negligence. By reason of the failure of the patient to prove the negligence alleged, the court held that the trial court erred in not directing a verdict for the physician. The judgment was therefore reversed and the cause remanded.

In a specially concurring opinion, Associate Justice Stephens stated that in his judgment the physician was guilty, under the evidence, of an actionable wrong which, if it had been submitted

to the jury, would have warranted a verdict awarding damages for mental anguish. The duty of a physician is to exercise that reasonable degree of learning, skill and experience which is ordinarily possessed by others of his profession in similar communities. This obviously includes a duty to furnish professional, not lay, care. The patient complained and proved that her body was exposed to the view and examination of a layman and to an operation performed by such layman, all without knowledge on the patient's part that he was a layman rather than a physician. While there was no direct statement by the patient in her testimony concerning mental anguish, a jury might reasonably draw inference from the fact that the patient was exposed to view, examination and operation in the manner described that she did suffer mental anguish. The fact that no physical injury came to the patient, observed Justice Stephens, was probably a happy accident rather than the result of any proper exercise of professional care, for while the lay person in question in the case, the district manager of a surgical supply house, might have acquired through practice in a laboratory or otherwise, for the purposes of sales demonstrations, skill in the use of the particular instrument so far as its actually touching and searing tissues is concerned, such person could hardly, for lack of general medical training and experience, be capable of meeting unexpectedly varied conditions or emergency consequences.—*Carr v. Shifflette* (District of Columbia), 82 F. (2d) 874.

#### Compensation of Physicians: Oral Promise to Pay for Services Rendered Employee.—

One Fritz Haven, an employee of the defendant, sustained a serious injury and the plaintiffs were summoned, by some person not identified by the record, to care for him. According to the plaintiffs' contention, the defendant requested them to spare no expense to save the employee's life and promised "that if the insurance company did not pay the expenses he would so do." The plaintiffs did care for the injured employee, employed a nurse, procured the necessary drugs and arranged for hospitalization. The defendant, apparently, refused to pay the bill and the plaintiffs sued him for the value of their personal services and also for certain sums allegedly owing to a drug store, to a nurse, to a hospital, and to two other physicians. The trial court gave judgment for the plaintiffs, the court of appeal affirmed that judgment (163 So. 189), and on relation of the defendant the case came before the Supreme Court of Louisiana.

The defendant objected to the introduction of parol evidence to establish his liability, on the ground that according to the petition the defendant promised to pay the debt of a third person and that, to be legally binding, such a promise must be in writing. The ruling of the trial court admitting the testimony was correct, said the Supreme Court. It is true, the court said, that even if the defendant did promise to pay the debt, if his purpose in making the promise was merely to answer for the debt of another, his promise could not be proved by parol testimony. But whether that was his purpose or whether he intended to obligate himself absolutely and become primarily bound to pay the debt was a question of fact which the court had a right to inquire into and to determine from the evidence. The trial court heard the testimony and the court of appeal reviewed it at length. Both courts held that the testimony showed that the defendant's promise to pay the debt was absolute and that it was supported by sufficient consideration. The Supreme Court, therefore, could find no reason for disturbing the judgment as to the item claimed by the plaintiffs for their personal services.

With respect to the other items, the Supreme Court held that the lower courts erred in giving judgment for the plaintiffs. The plaintiffs sued to recover these amounts "for the use and benefit" of the creditors named. According to the petition, it was necessary that the injured man have medicines, nurses, and that he be carried to a hospital and it was necessary to call a physician in consultation and another to administer an anesthetic. The plaintiffs' theory, in seeking to recover the amounts "for the use and benefit" of the other creditors, was that inasmuch as the defendant had told them to spare no expense necessary to save the life of the injured employee, they were his agents and were executing his mandate. If that be true, said the Supreme Court, the defendant is liable for the amounts, but it does not follow that the plaintiffs may

the rise. The authors agree with the hypothesis of Pappenheimer and Wilens that the hyperphosphatemia of renal insufficiency is the initiating factor in the chain of events which leads to parathyroid hyperplasia. It is conceivable that the increase in parathyroid activity constitutes a biologic defense against impending hypocalcemia secondary to phosphate retention.

**Plasma Effective in Accelerating Coagulation of Hemophilic Blood.**—Patek and Taylor think that their studies clarify the subject of blood clotting in hemophilia. If a scheme for blood clotting is accepted that involves only prothrombin, calcium and fibrinogen, both normal and hemophilic prothrombins function similarly. However, the addition of normal prothrombin accelerates the clotting of hemophilic blood, whereas the addition of hemophilic prothrombin does not. Hence, regardless of its behavior in a calcium fibrinogen system, there must be a specific alteration in the hemophilic "prothrombin complex." The clotting substance that is described by the authors is not dialyzable, but it does pass through a Berkefeld filter. Its range of optimal precipitation from plasma lies between  $pH$  5.9 and 6.4. It is thermolabile, insoluble in water at  $pH$  6.5, but soluble in isotonic saline solution. On dilution and acidification of filtered normal plasma there is formed a globulin precipitate, which, either fresh or dried in a vacuum, contains a clot-promoting substance for hemophilic blood. This substance is effective both in vitro and in vivo. The substance so obtained either gives reactions of a protein with the characteristics of globulin or is associated with such a material. However, hemophilic plasma yields a similar material, which has only minimal coagulation-accelerating activity. Therefore one may conclude at this juncture only that the clotting substance is precipitated with globulin, but there is no proof that it is globulin itself. The fact that normal globulin substance reduces the clotting time in vivo changes the disease from an abnormality that was immutably fixed to one that is amenable to change. Likewise the preparation of a relatively stable dry substance makes practical the further study of its properties.

#### Action of Crystalline Vitamin C on Herpes Virus.

Holden and Resnick studied the rôle of vitamin C in the inactivation of herpes virus outside the body, using the W virus because of its constant production of skin reactions when injected intradermally. While they show that the inactivation of W virus by cevitic acid is due to the fact that the latter produces an environment unfavorable to the viability of the infective agent by its  $pH$  effect on the virus suspension, other investigators have indicated that the inhibiting action of cevitic acid may be due to the structure of the molecule or to its great reducing power. Because cevitic acid is irreversibly changed above a  $pH$  of 5 at 37 C. (Borsook and Jeffreys, Barron et al.), the question arises as to whether the vitamin, when added to virus suspensions buffered above a  $pH$  of 5, remains unaltered. Small amounts of tissue extracts prevent

the aerobic oxidation of cevitic acid. Whether a tissue extract containing a living agent would behave similarly can be determined only by titrating such extracts for cevitic acid after the vitamin has been added. Since in the control series of the authors' experiments the virus was viable at hydrogen ion concentrations that theoretically should not destroy vitamin C and since the vitamin apparently exerted no inhibitory action on the virus within this range, it seems probable that the action of cevitic acid in this case is nonspecific and that its inhibitory effect on W virus in vitro is due to an acid effect.

**Thyrotoxicosis with Psychosis.**—In view of the lack of precise knowledge as to the relationship between the clinical symptoms and psychotic manifestations in thyrotoxic states and the accompanying neurohistologic alterations, Friedman and Kanzer review the clinical and anatomic observations in six fatal cases in which thyrotoxicosis played an important part. Only one of these was sufficiently clear cut to merit a detailed report. The clinical picture closely resembles that of other acute toxic exhaustive psychoses of most varying etiology. The unusually rapid recovery that took place after the intravenous administration of a single dose of thyroxine, following three weeks of unsuccessful therapy with sedatives, suggests the fact that the precipitating agent of the psychosis was some toxic condition related to the present disorder. Moreover, the thyrotoxic state existed before the psychosis for at least several years. Therefore the factor to account for the acute psychotic attack was apparently an exacerbation of the already existing condition (the mild thyrotoxic state), and from the history it is apparent that this factor was precipitated by a series of psychic and somatic traumas. The pathologic lesions in the brain of the patient, as shown by thickened meninges and the generalized astrocytosis of the subcortex and cerebellum, correlated with the long clinical history of the thyrotoxic state, indicate that the brain was damaged prior to the onset of the psychosis. However, the proliferation of oligodendroglia, which is usually associated with degenerative lesions, points to the probability that the stimulus was of an acute and intense nature. The gradual pathologic alteration of the nervous tissue during the severe and minor thyrotoxic state of several years' duration most probably altered the brain in its physiochemical reaction, so that an excess of a toxic agent liberated under the influence of psychic traumas was really responsible for the psychosis. In turn the toxic exhaustive state of the individual during the psychosis contributed further to cerebral damage. The neuropathologic changes, however, offer no explanation for the sudden fatal issue.

- Appendicitis: Series of Cases. J. P. Collier, Tuscaloosa.—p. 231.

**Meningococcal Meningitis.**—Clyde and Neely state that from January to June 1936 there were twenty-one cases of epidemic cerebrospinal meningitis reported in the city of Birmingham and in Jefferson County. Ten of the patients were given the meningococcus antitoxin developed by Ferry; treatment of the other eleven patients is not known, but eight of the eleven died—a mortality of 72.7 per cent, if the ten who recovered are excluded. The patients were given an average of 50,000 units (240 cc.) of the antitoxin. They spent an average of 13.7 days in the hospital. Only two of the ten had any permanent disability, one being totally deaf with some disturbance of equilibrium, the other partially deaf. There was no single case of anaphylactic shock from the antitoxin. Seven patients had a well marked urticaria and mild serum sickness. Three had no reactions. The last four patients received less antitoxin intraspinally and more intravenously. The last two were given only one dose intraspinally. In the future the authors plan to give all the antitoxin intravenously and to tap the spinal canal for drainage and relief of pressure when indicated. They feel that, if the patient looks clinically well, spinal punctures may be discontinued when the smear is negative even if the cell count is still 500 or more, if there are no signs of increased intracranial pressure.

**Serum Lipase.**—Comfort determined the degree of lipase activity of the serum by the amount of olive oil hydrolyzed by a given quantity of serum in a given period of time in normal persons and in patients with a variety of diseases. The upper limit of the values for lipase in the serums of persons without pancreatic disease appears to be about 1.5 cc. of twentieth normal sodium hydroxide. Elevated values for serum lipase have been found in 95 per cent of the cases of acute pancreatitis, in 36.5 per cent of those of carcinoma of the pancreas and in 60 per cent of those of carcinoma of the ampulla of Vater. The increased values in these diseases followed inflammation of the gland or obstruction of the pan-

creatic duct by carcinoma. Elevated values appear in cases of acute inflammation of the pancreas immediately after the onset of the attack, and as a rule they decline to normal levels within three weeks or even earlier. It appears that elevated values occur in acute inflammations of the pancreas so long as an adequate amount of lipase-producing tissue is present, and less frequently in malignant disease, depending on the presence or absence of obstruction of the pancreatic ducts or on the presence of inflammation associated with a malignant process in the pancreas. An elevated value for serum lipase does not of itself distinguish between inflammation and a malignant condition of the pancreas. The interpretation of the increase in lipase activity of the serum must depend on the associated clinical observations. If the symptoms suggest inflammation of the biliary tract, the elevated values for serum lipase will usually indicate an associated pancreatitis or obstruction of the pancreatic duct by a stone impacted in the ampulla. If the symptoms are more indicative of inflammation of the pancreas than inflammation of the biliary tract, elevated values for serum lipase should be confirmatory evidence of the clinical suggestion of pancreatitis. In the presence of a painless jaundice, elevated values for serum lipase will usually point to the presence of carcinoma of the head of the pancreas. If values for serum lipase rise rapidly following an acute attack of pain of the upper abdomen and then fall gradually or rapidly to normal levels, such behavior favors the presence of pancreatitis. If the values for serum lipase in the presence of a painless jaundice are increased and sustained at a fairly constant level, carcinoma of the head of the pancreas is probably present. If the values for serum lipase are elevated but fluctuating, carcinoma of the ampulla of Vater must be suspected. An acute pancreatitis associated with malignant disease of the pancreas may alter the type of curve and obscure the diagnosis. Values for serum lipase were elevated in 7 per cent of the cases of duodenal ulcer. Disease of the liver was associated with elevated values for serum lipase in 13 per cent of the cases.

**Silicosis and Tuberculosis.**—Gardner asserts that the lesions of silicosis and tuberculosis are essentially similar. In human beings in whom the two conditions are frequently associated it is often impossible to ascertain the etiology of a particular lesion. Proof of the similarity of the cellular response to silica and to the tubercle bacillus is drawn from a series of experiments on different species of animals, birds and fish. The primary mononuclear cell reacting to both silica and the tubercle bacillus is apparently the same. The two irritants seem to affect it in the same manner, producing the variations known as epithelioid and giant cells. Both agents cause exudation and necrosis of tissue with the liberation of free fat, and in each case this necrotic matter may become calcified. Both cause continued proliferation of mononuclear leukocytes and fibro-

the last patient it is concluded that pellagra and alcoholism were the factors responsible for the electrocardiographic changes, for, with clinical improvement, the alterations disappeared. A study of the weights of fourteen hearts from patients dying from pellagra, in whom there were no important pathologic lesions involving the cardiovascular apparatus, showed that the average heart weight for the men was 307 Gm. and for the women 255 Gm. It is highly significant that pellagra does not affect the heart to a degree sufficient to impair its functional integrity. There are no characteristic electrocardiographic changes in endemic pellagra. The changes that occur are invariably explained by vascular or toxic complications. Beriberi and pellagra have no comparable effect on the heart. The difference is so absolute that the authors venture the opinion that vitamin B<sub>1</sub> is not concerned with the pathogenesis of pellagra.

**Etiology of Pellagra.**—Their observations, together with the results of liver and stomach mucosa therapy, the frequent recovery of mild pellagra on a pellagra producing diet and the frequent failure of yeast therapy, seem to make it possible for Sydenstricker and Thomas to formulate the theory that pellagra is a conditioned deficiency of the same order as pernicious anemia and sprue, but more complex than either. The essential curative substance is produced by the interaction of an intrinsic factor present in normal gastric juice (and perhaps in the gastric juice and stomach of animals) with certain components of the vitamin B<sub>2</sub> complex. This essential substance is probably stored in the liver. Absence of the intrinsic factor and exhaustion of the stored essential substance result in the symptom complex of pellagra. The theory outlined can account for the occurrence of pellagra under varying conditions. Any agent that seriously damages the gastric secretory function over a considerable period may cause pellagra by failure of the intrinsic factor. If liver damage is added, the disease is rendered more severe. The relation of sunlight to the pellagrous eruption may well depend on a defect in the metabolism of hemoglobin or an undetermined disturbance of the hematopoietic system. It seems probable that photosensitization by porphyrins may be an important factor in pellagrous dermatitis. It is remotely possible that certain of the gastro-intestinal and neurologic symptoms may also depend on hematoporphyrinemia. It is possible also that this phase of pellagra is related to the gross hematopoietic disturbances of pernicious anemia and sprue.

**Artificial Menstruation Following Hysterectomy.**—Roberg outlines an operation for prolonging menstruation following hysterectomy and the results obtained from its performance in the clinic and private practice of Halban. The procedure consists in transplanting a piece of the mucosa of the removed uterus into either the vaginal wall or the cervical stump and is successful in the majority of cases. This artificial menstruation has a pronounced psychic value and may serve to postpone the physiologic menopause, which seems to occur at an earlier age than usual in cases of simple hysterectomy. The operation provides an experiment in which menstruation is continued by a comparatively minute portion of the uterus. It is thus an objective demonstration of the extent and regularity of menstrual function in the absence of the greater part of the uterus, and it leads to conclusions which may support the theory that the uterus plays an important primary part in the function of menstruation. Endocrine therapy in an attempt to revive transplant bleeding when it has ceased may serve to support the view that the activity of the transplant is dependent on ovarian activity.

**Sedimentation Rate in Scarlet Fever.**—Cookson performed the erythrocyte sedimentation rate test in seventy-six cases of scarlet fever. By comparing the temperature charts with the erythrocyte sedimentation rate curves it was seen that there was a rough similarity between them. Of the two the erythrocyte sedimentation rate test was the more delicate. Thus a few cases showed a raised erythrocyte sedimentation rate before the onset of a complication was heralded clinically by a raised temperature and other signs. A considerably raised erythrocyte sedimentation rate on the fourteenth day of the disease means either that complications have already developed or will do so. The test is useful in differentiating the types of albuminuria occurring in scarlet fever. A high rate means that the patient has acute nephritis which has an accordingly worse prognosis than the benign types of albuminuria. Most complications that occur in scarlet fever cause a raised erythrocyte sedimentation rate before they give symptoms and signs, and also while the complication lasts. The exceptions are benign albuminuria and serum reaction. There is no definite relationship between the other blood changes recorded and the erythrocyte sedimentation rate in scarlet fever. It is a useful index of the efficacy of treatment. It is altered by a change in plasma protein causing increased aggregation of red cells by alteration of the viscosity and indirectly related electrical burdens.

**Metabolic Factor in Chronic Rheumatism.**—Gordon points out that, while fibrositis is sometimes associated with the infective group of arthritis, its presence is of minor importance in virtually all cases, and it is not usual to pay much attention to it in the treatment of these conditions, though, if a little more notice were sometimes taken of this intervening malady, the comfort of the patient might be increased and he might be relieved of a certain degree of unnecessary pain. In the osteo-arthritis group, however, fibrositis is present in every case and is frequently of marked importance. Not only is it widely distributed, but it is often found that a great deal of the pain, stiffness and coincident discomfort is due to the fibrositis rather than to the arthritis. Since treatment of fibrositis is much easier and more rapid than that of the arthritis, it should be instituted. Fibrositis is in the majority of cases metabolic rather than infective in origin and frequently due to the same sort of factors as osteo-arthritis: strain, poor vascularity and inefficient circulation and elimination. Infective foci, if they exist, may be the direct cause of fibrositis but may act by upsetting the metabolic balance and thus cause its onset. Fibrositis may occur in those suffering from subhypothyroidism or autonomic imbalance. The characteristic thickenings of fibrositis are due to a fibrous barrier of resistance laid down round irritative metabolites. These thickenings may exist before

**Banti's Disease with Gastrorrhagias and Thrombophlebitis.**—Serafin divides the causative factors of gastrorrhagias in Banti's disease into mechanical and physiopathologic. The enlargement of the spleen may compress the lienal vein, which may also establish secondary traumatic changes in the wall of blood vessels leading to aseptic thrombophlebitis of the splenoportal veins. That the size of the spleen, of itself, is not a sufficient factor in obstructing the venous flow from the spleen is demonstrated by splenomegalies of other diseases without gastric hemorrhages, such as Gaucher's. The tendency to gastrorrhagias is due to a disturbance of the hemolytopoietic system. The physiopathologic factors that lead to gastrorrhagias have their origin in the functional disturbance of the reticulo-endothelial system and express themselves in the histopathology of the spleen and splenoportal region. The great amount of blood demanded by the enlargement of the spleen is impeded in its course, thus raising the intravenous pressure in splenoportal and gastro-esophageal areas. Whether gastrorrhagias are due primarily to overdistention of the gastro-esophageal plexus or are dependent on some other physiopathologic factors is not determined. It appears that thrombophlebitis is a part of Banti's syndrome, its presence depending on the stage of the disease and the severity of the hemolytopoietic dysfunction as it affects the spleen. Stasis of the splenic vein, the occurrence of thrombocytopenia and the traumatic and toxic injury to the intima will predispose to thrombophlebitis. This occurs in the third stage of Banti's disease, and in about 30 per cent of cases it is associated with ascites and cirrhosis of the liver. Clinically the presence of gastrorrhagia and the absence of ascites virtually excludes Banti's disease. Perisplenitis with multiple adhesions of the spleen to its surrounding viscera and adhesions of the omentum to the anterior abdominal wall indicate the presence of congestion in the splenoportal region and an attempt to establish collateral circulation. The results of splenectomy are satisfactory in that noxious substances causing splenomegaly and anemia are removed; the general condition of a patient is improved and in many cases life is prolonged from two to twenty-five years. Splenectomy, however, does not prevent recurrence of gastrorrhagias in some cases. When cirrhosis of the liver secondary to splenic anemia is advanced beyond the possibility of repair, passive congestion in the gastro-esophageal varices will persist after splenectomy unless efficient collateral circulation is established. To obviate any possibility of gastrorrhagias, an early recognition of splenic anemia and early splenectomy must be performed before the onset of cirrhosis of the liver and passive congestion of the gastro-esophageal veins take place.

### Mental Symptoms in Cases of Subtentorial Tumor.

—In 120 cases of subtentorial tumors observed personally, Keschner and his associates elicited mental symptoms in fifty-six. In sixty-three of the 120 cases the diagnosis of tumor was verified by operation and in fifty-seven by necropsy. The material was analyzed from the point of view of disturbances in sensorium, affect, memory and orientation, intellect and higher psychic functions, changes in personality, sphincteric control and the psychosexual sphere. Many patients presented mental changes so slight that unless one searched for them with great care they could have escaped detection. The mental symptoms were milder and less complex in children than in adults; this may have been due to the greater technical difficulty in eliciting slight disturbances in affect, memory and orientation and intellect in children. Mental symptoms in cases of subtentorial tumor were much milder and less complex than those in cases of supratentorial tumor. Crude visual hallucinations of the type usually observed in cases of supratentorial tumor may occur in cases of infratentorial tumor. They were present in four patients of the series. The early appearance of profound and complex mental changes, especially those involving disturbances of memory and intellect in a patient whose only evidence of tumor of the brain is intracranial hypertension, is in favor of localization of the tumor above the tentorium; in this sense the mental picture in a patient suspected of having tumor of the brain may perhaps be of some localizing value. Too much reliance, however, is not to be placed on the mental picture for this differentiation.

**Osteomyelitis of Sphenoid Bone.**—Lawson reports two cases of osteomyelitis of the sphenoid bone, one of which was produced by extension from petrositis and one by reactivation of an old infection of the sphenoid sinus. In the first case an unusual amount of destruction of the sphenoid body developed before the onset of diffuse fatal basal meningitis. In the second case neither meningitis nor thrombosis of the cavernous sinus, which are the more usual complications, developed, but the process took the unusual outlet of posterior cervical thrombophlebitis, with abscess formation and late septicemia. There was a continuous stream of pus from the abscess beneath the dura under the cavernous sinus and over the sphenoid body,

**Chronaximetric Studies in Catatonia.**—Last and Ström-Olsen selected seven well marked stuporous catatonic patients and performed chronaxia measurements on muscles of the upper and lower limbs. The method employed was that of Bourguignon. The interpretation of abnormal chronaxia values is extremely difficult. If it is assumed that an organic constant change in some parts of the central nervous system can be regarded as the cause of catatonia, constant changes of chronaxia might be explained; but further corroborating evidence is required in this connection. The explanation, which seems a possible one to the authors, is the assumption that the changes of chronaxia are due to the maintenance of certain muscular contractions (increased tone) over long periods. Previous investigations of chronaxia during voluntary muscular contraction have shown no abnormal features, but such voluntary contractions were necessarily of comparatively short duration, though work and fatigue seemed to change the chronaxia for short periods. When one bears in mind that catatonic patients frequently maintain the same muscles in a state of contraction (increased tone) over long periods, it seems reasonable to suppose that the changes found are secondary to these prolonged contractions or increase of muscular tone. The view is held that the autonomic nervous system is involved in the maintenance of muscular tone. In this connection an increased or changing sympathetic tone can be responsible for changes in chronaxia. It has been shown experimentally that chronaxia can change with alteration of the balance between the cerebrospinal and the sympathetic system, although these changes did not reach the degree recorded in the present cases.

**Effect of Acetylcholine on Symptoms of Anxiety.**—Jones chose six cases of anxiety neurosis, each showing somatic manifestations of anxiety, such as tachycardia, palpitations, tremor, sweating, vasomotor instability, giddiness, weakness and feeling of constriction in the throat or chest, for treatment with fourteen daily injections of carbaminoylcholine chloride, 0.00025 Gm. subcutaneously. This drug has an action similar to that of acetylcholine and is a stimulant of the parasympathetic nervous system. The results obtained from subjective and objective observation in these cases were in accord with the original conception that the symptomatology could be understood almost entirely in terms of autonomic imbalance, and in those cases in which it was possible to reproduce with epinephrine the somatic symptoms of anxiety the psychic manifestations of fear were at the same time reproduced. That in an attack of acute anxiety the symptoms are almost wholly referable to the sympathetic nervous system is evident from the symptoms complained of by these patients during an attack, and the cessation of symptoms following stimulation of the parasympathetic nervous system is in support of this. There would appear to be some justification for this line of treatment in cases showing attacks of acute anxiety, provided this is in no way meant as a substitute for psychotherapy and merely aims at giving the patient more rapid relief from the distressing symptoms accompanying anxiety than could be

attained by purely psychologic methods. Relief from the psychic and somatic symptoms of anxiety resulted in all cases, but they tended to relapse following withdrawal of the drug.

**Investigation of Pfeiffer's Bacillus Infection.**—Smorodintseff and his collaborators inoculated eighty volunteers from 17 to 42 years of age, who had no noticeable disturbance of the heart, the lungs or other viscera and in whom the mucosa of the air passages was in a normal condition, with cultures of Pfeiffer's bacillus. Pfeiffer's bacillus on being introduced into the respiratory tract always thrives there, being present in high concentrations in the mucosa of the nose and the throat within the first five to ten days following inoculation. The pathologic reactions and inflammatory phenomena developing on the mucosa of the respiratory passages had no noticeable effect on the content of these micro-organisms in this region. The experimental infectious process that is caused by inoculating people with Pfeiffer's bacillus is not followed by an activation of the main causal organisms producing the secondary complications that usually accompany influenza. Therefore the symptoms developed by persons who had been subjected to infection can reasonably be attributed to the toxic products of Pfeiffer's bacillus but not to the secondary processes of a streptococcal or pneumococcal nature. Inoculation with Pfeiffer's bacillus by means of inhalation, particularly if it is repeated, always led to a distinct rise in the concentration of specific agglutinins and complement fixing substances in infected individuals. In from four to six hours following inoculation, clinical symptoms developed which indicated that the patient was in a condition of infectious intoxication of a greater or lesser severity, lasting for one or two days. The picture shown by the blood in the experimental infection caused by Pfeiffer's bacillus was the reverse of that observed in epidemic influenza. All the volunteers who were infected showed a marked leukocytosis in the few hours immediately after the inhalation. An increase was also observed in both the relative and the absolute quantity of neutrophils, which showed a definite shift to the left in the direction of younger cells, the neutrophil curve reproducing that of the leukocytes. The absolute quantity of lymphocytes was above the normal level in every case. The reaction of erythrocyte sedimentation was found to be greatly accelerated in the infected volunteers. Thus there is every reason to

and in one case to 1,000,000 units daily. The higher dosages were administered only when the patient was in the hospital, where close observation was possible. In the usual case a daily dose of 200,000 units or more as indicated was maintained throughout the period of treatment. When the higher dosages are being administered, symptoms usually consisting of dizziness, nausea, increased micturition and slight diarrhea appeared, though they seldom appeared on dosages less than 400,000 units a day. When the dose is reduced to 200,000 units a day or less, the symptoms promptly disappear and subsequently the dose may be increased without the reappearance of these symptoms. The diets of the patients have been regulated or advised along the lines of natural foods. In especially severe or stubborn cases, when the economic status of the patient would permit, hyperpyrexia was used. In severe cases of atrophic arthritis, the reduction or disappearance of pain was observed. Roentgenograms have shown remarkable reparative changes in the joints, consisting of filling in of the rarefied regions and reconstruction of cartilage. In severe cases of hypertrophic arthritis, granular resorption of exostoses, particularly on vertebrae, and reconstruction of cartilage takes place. Not a single patient has failed to respond in some degree to the high vitamin D therapy. Not only were the symptoms of pain and reduced movement of joints relieved, but the general nutritive state was greatly improved. This was manifested by gain in weight, appearance and feeling of well being. There is in the mass charge of vitamin D a new therapeutic measure which appears to offer much hope in the treatment of arthritis and kindred conditions.

#### Thrombocytopenic Purpura Due to Food Allergy.—

Squier and Madison have observed three patients with primary thrombocytopenic purpura in whom drug allergy, toxic changes and hematopoietic disease could be excluded; in their search for the etiology, food allergy was considered. Treatment excluding suspected foods was followed by striking clinical improvement and a concurrent gradual but marked rise in the thrombocyte level in each patient. To demonstrate further the relation of specific foods to the thrombocyte level, hematologic studies were made following the ingestion of suspected foods as soon as the clinical condition of the patient justified it. This was followed by recurrence of bleeding and a suggestive lowering of the thrombocyte count. In two of these patients temporary depression of the thrombocytes was observed thirty minutes after ingestion of some but not all foods that caused a leukopenic response and associated eosinophil rise. This depression of thrombocytes occurred coincidentally with the maximal depression of leukocytes and rise of eosinophils and was not observed after ingestion of foods that caused normal digestive leukocytosis. A similar thrombocyte depression after

ingestion of specific foods was observed also in a group of three patients with unexplained bruising and hemorrhagic tendencies in whom the blood pictures were essentially normal. It is generally accepted that allergic reactions to foods may be responsible for alterations in capillary permeability, and the authors believe their observations indicate that a similar allergic response to foods may depress the thrombocyte level sufficiently in certain cases to produce typical essential thrombocytopenic purpura. Food allergy should be regarded as only one of many possible etiologic agents in thrombocytopenic purpura. An allergic investigation of patients with this disease offers a far more hopeful therapeutic approach than do the empirical and nonspecific methods of treatment so universally employed at the present time.

**Hyperparathyroidism in Kidney Disease.**—Highman and Hamilton show that there is no proportion between the increase in parathyroid function and the rise of the inorganic phosphorus of the serum in nephritis; but since the phosphorus was generally elevated in the cases that showed increased parathyroid function, their data are not in discord with the theory proposed by Pappenheimer and Wilens. However, one patient in the series had developed high arterial tension, albuminuria and convulsions during pregnancy one and one-half years before the last admission and had delivered a stillborn child. On the last admission she showed no evidence of parathyroid hyperactivity; the serum phosphorus was extremely high, and the serum calcium was below the tetany level. Two weeks after admission in uremia, she developed convulsions and died a week later, showing signs of pulmonary edema and shock. Here it may be assumed that the lack of compensatory parathyroid hyperfunction allowed a profound imbalance of the calcium metabolism. The failure to elicit an elevation of the rabbit's blood calcium by the injection of the solution containing certain constituents of uremic blood indicated that these substances in uremic blood are not responsible for the reaction. This experiment, however, does not in any way eliminate the possibility that other substances in uremic blood are responsible for

tive lesions commonly found in secondary syphilis. In analyzing the cases with respect to the effect of antedated treatment on the course of syphilis, in seventy-six individuals no signs of secondary syphilis had been observed. Of this number fifty-eight had received arsenical treatment during the period of the primary chancre, three had taken only oral medication of unknown nature, and fifteen had never been treated. Of ninety-three cases, all showing signs of secondary syphilis before the appearance of meningitis or giving a history of recent infection, eighty-two had been treated with an arsenical drug, four with drugs by mouth and seven had not been treated before the onset of meningitis. A succession of relapses with intervening treatment irregularities occurred in fourteen patients. The spinal fluid was examined in one case of primary and seven cases of secondary syphilis before any antisyphilitic treatment was given. The results revealed the presence of meningeal involvement in six patients, none of whom exhibited signs or symptoms of neurosyphilis at the time of spinal puncture. Each of the eight patients later developed acute symptomatic meningitis after inadequate arsphenamine therapy. The immediate results of treatment are usually satisfactory. With the exception of deafness following involvement of the eighth nerve, paralysis of the cranial nerves disappears with a fair degree of promptness. Deafness may persist and be uninfluenced by treatment. Even in cases in which there is an immediate improvement in hearing, a permanent residual impairment is not infrequent. Brilliant results in the immediate improvement of vision have been observed when treatment has been given within a few days after the onset of visual failure, a convincing demonstration of the efficacy of the arsphenamines.

**The Huhner Test in Diagnosis of Sterility.**—Huhner has seen cases in which the most painstaking investigations of the entire male genito-urinary system neither reveals the cause nor is a cure for necrospemia effected by any known method. He has seen cases in which many condom specimens have been examined with all the necessary precautions observed and has always found only dead spermatozoa in the condom, and yet a postcoital examination (Huhner test) revealed many lively normal spermatozoa. In some of these cases the spermatozoa removed from the female genitals after coitus remained alive for several hours under the microscope, while in the condom specimen they were found dead within twenty minutes. The only reason the author can advance for this phenomenon is that the female genital secretions seem to have the power to preserve the vitality of the spermatozoa much more than the ingredients of the semen proper. The foregoing may also explain those cases in which necrospemia, according to condom examinations, was always present but still the female finally became pregnant. Therefore no observation of a condom specimen, no matter by what method examined, can give such a definite diagnosis as can be made by examining the spermatozoa removed from the female genitals after coitus.

Hemiplegic Forms of Hutinel's Disease. A. Carrou, H. Mourigan and C. M. Barberousse.—p. 826.

**Bovine Bacilli and Tuberculous Meningitis.**—Lesné and his associates found that in the majority of cases of tuberculous meningitis there are persons in the immediate surroundings of the child who are giving off bacilli. Often there is no direct evidence of contagion. The bovine type of bacillus is possessed of a virulence equal to that of the human type. This is especially true of Scandinavian countries and of England, where the consumption of crude dairy products is large. Of 130 cases studied, nine furnished the bovine type, the cultures of which grew slowly and were by far less abundant in colonies than the human type. An intravenous injection of this type into a calf produced a visceral and especially a serous tuberculosis within four months. The liver and spleen were studded with numerous tuberculous nodules. The serosa and the renal parenchyma likewise presented disseminated nodular lesions. The mesenteric ganglions were hypertrophic and the visceral membranes showed copious new formations. Similar formations occurred in both pleurae and in the bronchial and mediastinal lymph nodes. No atypical forms were found, and it could be said that the source of contamination must be contaminated milk. Up to 100,000 virulent bacilli were counted for each cubic centimeter of milk. The manner of treating the udders and keeping the animal clean is mostly responsible, and it has been found that not only the milk but other dairy products, such as butter and cream, carried the contamination. The observation was also made that all these children had stayed in the country and for many months lived mostly on dairy products. In all these cases the cerebrospinal fluid contained the bacilli, and it was demonstrated that the incubation of the liquid on elective mediums gave 100 per cent results. More attention should be paid to the treatment of milk at the place of production.

**Erythema Nodosum.**—In discussing the tuberculous origin of erythema nodosum, de Biehler feels that this theory is increasingly gaining ground. It is confirmed by the following data: (1) presence of Koch's bacillus in the nodules, (2) anatomopathologic signs in the erythema, (3) reaction to tuberculin, (4) presence of Koch's bacillus in gastric contents, (5) roentgenologic examinations, (6) clinical signs and (7) identical action of ultraviolet rays on the nodules of erythema and on tuberculous skin papules (one as well as the other diminished in size after three or four applications). Tuberculin administered after the disappearance of the nodules makes them reappear. Independent of this view are authors who maintain that erythema nodosum originates in different infectious diseases (measles, pertussis, chickenpox, rubeola). This disease may, as in measles or whooping cough, serve as an initiating factor for the development of tuberculosis. It has also been proved that the streptococcus taken from an angina and injected in the form of an emulsion gave rise to erythema nodosum in animals. On the other hand, Koch's bacillus injected into these animals produced no such disease. Others again maintain and deny the theory that Koch's bacillus lives in symbiosis with the germs of erythema nodosum as well as of rheumatism. The author regards the cutaneous nodule as an allergic reaction of the skin. She had under observation 107 children ranging in age from 6 months to 15 years. Eighty had positive tuberculous reactions and twenty-five cases were preceded by autonomous diseases, twenty-six by measles, twenty by varicella, seventeen by angina, twelve by grip, four by rubella and two by pneumonia. In two cases there developed

as the chloramides, and found a combination of acriviolet (a mixture of acriflavine and gentian violet) and brilliant green to be the most powerful antiseptic against the gram-positive organisms that will not injure living cells. It also has a high specificity against the gram-negative organisms. In broth cultures and in the test tube it will not let gram-positive organisms grow in dilutions of one to one million, nor gram-negative organisms in one to ten thousand. In concentrations of one to one thousand it has a high phenol coefficient against all the pyogenic organisms. When applied to a burned area, it rapidly forms a tough, flexible eschar which seals off the burn, sterilizing it at the same time. The eschar thus formed prevents fluid loss and brings about analgesia by protecting the nerve endings. An aqueous solution of the dye is sprayed on by means of an atomizer. There is no clean-up done unless gross contamination is present. The burned area is sprayed every hour during the first day, by which time the eschar is formed. When this has taken place, the spraying is discontinued and the eschar is watched carefully every day for any contamination. If any infection occurs under this eschar, it is not masked as it is under the tannic acid crust. The area directly over the infection becomes moist and soft. This contaminated portion should be lifted up with a pair of tissue forceps and excised. The underlying area is then dried with a sterile sponge to remove any gross contamination and the dye is reapplied. Inspection continues until healing under the eschar is complete or until the granulating surface has been built up to the proper height to accept skin grafts. While the new dye is as superior to gentian violet as gentian violet is to tannic acid, it is not the final answer to all the problems presented by a burned patient. The author is certain that the conception of a burn as an infected surgical lesion is correct, and that it is infection rather than absorption of a split protein which causes death in burns; for when there is no infection there is no toxemia.

**Physical Handicaps of School Children.**—Payne gives a summary of the physical defects found in a group of 5,412 children attending the grade schools in Dayton, Ohio. Three fourths of the children show one or more physical handicaps of either major or minor significance. Physically the grade school child of today is rather far from the goal that pediatricians have constantly been striving to attain. Of the children examined, 3,102 showed some degree of dental caries or malalignment with malocclusion. More than half of the children needed dental attention. Underweight of 10 per cent or

more was found in 23 per cent. The graph of malnutrition as expressed by this group of children is particularly interesting because of the fact that the child aged 6 years and the one aged 11 years seem to be the most underweight. In the intervening years and from 11 years on, however, the cases of malnutrition decrease quite noticeably. Hypertrophied or diseased tonsils and adenoids ranked third in frequency among this group of childhood defects. Of the children inspected, 20.7 per cent showed evidence of nasopharyngeal abnormality. A graph designating diseased tonsils and adenoids showed that the child aged 9 years was the most commonly afflicted with disease or hypertrophy of the adenoids and tonsils. In the examination of children from the third to the eighth grades inclusive, 19 per cent, through means of the visual acuity tests, were detected to have defective vision. Since about one child out of every five within the third to the eighth grade does not have proper sight, owing to refractive errors primarily, sight conservation measures within a city or state medical regimen should be constantly instituted to combat this ever menacing entity. Only 4.9 per cent of the children were discovered to have palpable thyroids. These varied from one plus to three plus in size. The graph for goiter shows a gradual but progressive increase in incidence of goiter from lower to higher grades. The highest incidence was found in the eighth grade. Skin diseases ranked sixth in frequency, 2.4 per cent, varying from the chronic eczemas to the contagious skin lesions of either infectious or parasitic origin. Other childhood handicaps, such as those associated with the heart, the speech and the hearing, occurred, but with far less frequency.

**The Heart in Endemic Pellagra.**—Porter and Higginbotham conducted a study of the heart in twenty-five endemic cases of pellagra assigned to their hospital wards for treatment during the last five years. Ten patients showed changes in the electrocardiogram. Of these, five had vascular disease, one purulent otitis media, one pyelitis, one diabetes, one rectal stricture and purulent colitis and one chronic alcoholism. In

normal children. In the latter, the behavior of uric acid eliminated during the concentration and dilution tests parallels the variations of specific gravity, rising in the concentration test and falling in the dilution test in accordance with the specific gravity. With the sodium nucleinate tolerance test the amount of uric acid eliminated varies within 1.6 and 1.8 Gm. per thousand cubic centimeters of urine. The amount of uric acid eliminated during the test rapidly increases for the first two hours and decreases at the same velocity for the next two hours, when it returns to normal. The graph of elimination of uric acid during the test shows a curve of rapidly increased elimination and diminution with a central part in the form of a pyramid. In children convalescing from glomerulonephritis the elimination of uric acid during the concentration and dilution tests parallels the variations of specific gravity. The graph of elimination of uric acid during the sodium nucleinate tests shows two different types of abnormal curves. The curve of the first type rises slowly, reaches figures lower than those of normal elimination (1.2 Gm. per thousand cubic centimeters of urine), forms a plateau of prolonged duration and drops again slowly. The curve of the second type rises to 0.5 Gm. of uric acid per thousand cubic centimeters of urine in the form of a pyramid. According to the author the sodium nucleinate test is more sensitive for functions of the kidney than the tests in common use for this purpose. The author states that uric acid is secreted by the kidney and that it has a threshold of renal elimination.

Action of Insulin on Metabolism of Proteins in Diabetes. V. Gaudio and S. De Blasi.—p. 1.

\*Roentgen Intracranial Images in General Arterial Hypertension. T. Lucherini.—p. 18.

Rôle of Endocrine and Neurosympathetic Disturbances in Pathogenesis of Exophthalmic Goiter. A. Salmon.—p. 47.

**Roentgen Intracranial Images in Arterial Hypertension.**—Lucherini made x-ray studies of the head in 104 patients suffering from various forms of arterial hypertension. He found x-ray signs of intracranial hypertension (especially increased circulation of the diploid canals) in 85 per cent of the cases. The presence of intracranial hypertension was confirmed by the results of determination of the pressure of the cerebrospinal fluid (Claude's manometer), which gave early figures above normal. In all cases of associated intracranial and general arterial hypertension the sella turcica was deformed. The author discusses the relations between intracranial and general arterial hypertension and the genetic mechanism, primary or secondary, of the latter in relation to the former. The two phenomena superimpose each other with reciprocal influences originated in a vicious circle. According to the author, the x-ray image of the head, showing intracranial hypertension in patients suffering from general arterial hypertension, has the value of a new index of craniographic semeiotics. The duration of general arterial hypertension can be evaluated from the intensity of the x-ray signs of intracranial hypertension. The more diffuse and intense the latter, the "older" the former. The author discusses the importance of the hypophyseal-meso-encephalic system as a central factor in regulating circulation. In this connection he calls attention to the pathogenic rôle of disturbances of the hypophyseal-meso-encephalic system in arterial hypertension, which is pointed out by the abnormalities of the sella turcica found in patients suffering from both intracranial and general arterial hypertension.

### Riforma Medica, Naples

53: 1-40 (Jan. 2) 1937

Protamine Insulin in Therapy of Diabetes. S. Caccuri.—p. 3.

\*Dextrose Therapy in Poisoning from Fungi. P. Moretti.—p. 9.

Catatonic Schizophrenia with Degenerative Lesions of Putamen: Case. M. Cahane and T. Cahane.—p. 14.

**Dextrose in Fungus Poisoning.**—Moretti reports satisfactory results from the administration of dextrose in four cases of poisoning from *Amanita phalloides*. On admittance to the hospital the patients were suffering from a gastro-enteric syndrome with intense abdominal pains, vomiting and diarrhea and vertigo. There was marked hypoglycemia in all cases. The treatment consisted of two daily injections of 30 cc. each

of a 20 per cent solution of dextrose, a daily proctoclysis of 1,000 cc. of a 47 per thousand dextrose solution and daily administration of 100 Gm. of saccharose syrup by mouth. The patients were kept on a milk diet all through the treatment, which lasted for five days and induced recovery of the patients. According to the author, dextrose normalizes the sugar metabolism and prevents general intoxication of the organism. Further work on poisoning from other fungi is advisable for verification of the actual value of dextrose treatment in fungus poisoning.

Foreign Body Spontaneously Eliminated by Vomiting: Case in Infant. A. S. Sein and F. García Rey.—p. 114.

**Vitamin C in Blood.**—Castex and Scheitegart found that the amount of vitamin C in the blood of persons suffering from various pathologic conditions (infections, cardiorenal, gastro-intestinal, hepatic and metabolic disturbances, diseases of the blood and of the endocrine glands and cancer) is diminished in comparison to that of normal persons (average of 1.9 and 4.2 mg. per hundred cubic centimeters of blood, respectively). An insufficient amount of vitamin C in the diet and an increased organic consumption of the vitamin in pathologic conditions are the causal factors. Vitamin C insufficiency plays no part in the development of the given pathologic condition. It is induced by a diminution of the organic resistances in pathologic conditions and, once established, has an unfavorable effect on the evolution of the disease. A proper diet, both in quality and in quantity, prevents the development of vitamin C insufficiency. After its establishment, supplemental administration of vitamin C controls the insufficiency. The author advises further work on the mechanisms of absorption, assimilation and elimination of vitamin C in order to clarify the causal factors involved in the establishment of insufficiency in certain pathologic conditions and its consequences. This clarification is of importance for etiopathogenic interpretation and treatment of diseases associated with vitamin C insufficiency in the blood.

\*Granular Images After Hemoptysis. P. González Battle.—p. 61.

Spontaneous Elimination of Tenia: Case. A. Hernández.—p. 67.

**Granular Images After Hemoptysis.**—González Battle says that all mild cases of granulitis of the lung in which the roentgenograms of the lung are similar to those of acute miliary tuberculosis, including posthemoptotic granulitis, have been classified under the general group of cold granulitis, which is erroneous. The characteristic of cold granulitis is the presence in the roentgenograms of the lung of round shadows, from 1 to 3 mm. in diameter, with borders lighter than the center of the shadow, on a dim gray background of reticulated appearance in patients, especially young adults, suffering from tuberculous allergy without fever or fibrocaceous tuberculosis. Granulations in the lung after hemoptysis are similar to cold granulitis from a roentgen point of view. They appear in the evolution of fibrocaceous tuberculosis and in a few weeks become smaller and darker in the roentgenograms and disappear. Disappearance of the granular shadows from the lung roentgenograms coincides with general improvement of the patient. According to the author, posthemoptotic granulitis is a special form of evolution of fibrocaceous tuberculosis which is due to the presence of exudates originated in hemoptysis. Granulations as well as exudates disappear by administration of gold treatment and complete rest of the patient. The author advises limiting the diagnosis of cold granulitis to the cases belonging to the type. He reports a case in which the roentgenogram of the lung was similar to that obtained in cases of

clinical manifestations show themselves. The latter occur when a threshold of irritation is passed. Treatment consisting in removal of septic foci, and administration of vaccines is, as a rule, disappointing. The dietary, endocrine and autonomic balance must be readjusted, and the thickenings removed by short wave diathermy or massage and hot baths.

**Edema in Congestive Heart Failure.**—Smirk investigated the factors that affect the passage of fluid through the capillary blood vessels in normal subjects and in cases of congestive heart failure, so as to ascertain the conditions that lead to the development of edema in the heart failure cases. He discovered that in congestive heart failure there is a fall in the colloid osmotic pressure of the plasma, and some protein passes through the blood vessels with the edema fluid. The colloid osmotic pressure of the protein of this edema fluid has varied between 1.5 and 7 cm. of water and this acts in opposition to the colloid osmotic pressure of the plasma. Thus the effective colloid osmotic pressure is reduced and as a result the reabsorption of fluid back into the blood vessels is decreased. Active muscular movements of the legs diminish the venous pressure in the legs by from 10 to 100 cm. of water. Thus the incapacity for exercise of patients with heart failure increases the average venous pressure in the legs to much above the normal. This increase is produced mainly by their muscular inactivity and to a much smaller degree by the increase in general venous pressure. The increases in the general venous pressure in cases of congestive heart failure are not by themselves sufficiently great to cause edema. All factors increasing the local venous pressure, however, will increase the effective filtration pressure and thus will increase the rate of transudation of fluid out from blood vessels. Conversely the counterpressure of the edema fluid on the outside of the blood vessels, which is exercised as the edema accumulates, will decrease the rate of transudation of fluid. The permeability of the blood vessels to water and to crystalloids is demonstrably increased in congestive heart failure and this augments the rate of loss of fluid from the blood vessels. The increase in the permeability of the blood vessels to water and to crystalloids may be such that with equal effective filtration pressures the rate of transudation of fluid in congestive heart failure is twice the normal. Despite such an increase in capillary permeability, fluid will leave the blood vessels only in situations in which the effective capillary pressure exceeds the effective colloid osmotic pressure of the plasma. The magnitudes of the various factors that combine to cause edema in congestive heart failure differ from case to case. Two of the important causes of such edema, the increase in the capillary permeability and the fall in the colloid osmotic pressure of the plasma, are also partly responsible for the edema in the nephrotic stage of glomerulonephritis.

**Mechanism of Arterial Hypertension in Acute Nephritis.**—From a study of six cases of acute nephritis, Pickering suggests that in some, and probably most, cases of acute nephritis hypertension is due to vasoconstriction of vasomotor nervous origin. Vasoconstriction of nervous origin might conceivably arise either by the presence in the blood of some centrally acting pressor substance or by a reflex mechanism. The latter possibility is the more probable, and it is natural to look for the origin of such a reflex in the organ which alone shows

constant anatomic abnormalities in acute nephritis, the kidney. Arnott and Kellar have shown that in the rabbit the hypertension which ordinarily accompanies oxalate nephritis does not appear if the kidneys are denervated previously. The conception of hypertension originating reflexly from the kidney in acute nephritis is not new but does not conform with recently expressed opinion. The majority of recent investigators suppose that the rise in blood pressure in acute nephritis is an expression of some primary disturbance in the vascular system, the exact nature of which is uncertain. The method of producing the disease tempts one to suppose that in the rabbit the hypertension results from the renal lesion; but it is to be borne in mind that as yet no adequate lesion of the kidney has been demonstrated at the time of onset of hypertension. In patients with acute nephritis the maximal rates of heat elimination are at or above the upper normal limit, whereas in the patients with chronic nephritis and other forms of persistent hypertension the maximal rates of heat elimination are indiscriminately scattered within the normal limits. When it is recalled that the degree of hypertension exhibited by the patients with acute nephritis was small in comparison with that ruling in the other conditions, the probability of an essentially different mechanism is evident.

**Amebiasis and Appendicitis.**—Banerji and his associates found that the incidence of amebiasis associated with appendicitis in 475 cases was 5 per cent. There was a positive history of dysentery within a period of twelve months in 45 per cent of the cases. In 56 per cent a course of emetine treatment was carried out with apparent benefit, before the patient was admitted to the hospital. In a series of twenty-five private cases, in which no emetine was administered before the operation, cysts of *Endamoeba histolytica* were found in the scrapings of the appendicular mucosa in every instance. Sigmoidoscopy is a valuable diagnostic aid in this type of case. In twenty-eight consecutive cases, stools were positive for cysts in eleven and parasites were present in the scrapings in three. Ulcers were present in twenty-five cases and stricture in six. The therapeutic test with emetine was positive in two cases. There were twelve cases of nonspecific colitis. The pathologic report showed inflammation of the submucosa with some fibrosis. Colonic lesions are readily amenable to preoperative emetine treatment, but patients are liable to subsequent attacks of appendicitis, as a result either of inflammatory changes in the appendix or of the recurrence of amebic lesions in the appendix. Local tenderness, as elicited by palpation over the roentgenologically visualized appendix or the appendicular region, is a reliable diagnostic sign in approximately 90 per cent of cases. Malformation of the base of the cecum after a barium sulfate enema is valuable and dependable. Such changes may vary from simple alteration in the mucosal silhouette to complete lack of filling. Pericecal cellulitis and appendicular abscess undoubtedly occur as a complication of chronic amebiasis. In active cases of amebiasis the parasite can usually be found in the feces; the specific treatment should first be used to cut short the pathologic process. In appendicular dyspepsia or neurasthenia a great deal of care and discrimination is needed in the selection of cases for operative treatment.

2 months and 14 years. The vitamin A preparation was given in addition to the usual diet for a period of two or three weeks. The doses were decided on the basis of the body weight and they always remained within the range of the therapeutic dose. In thirteen of the twenty children the vitamin A produced a noticeable modification of the thrombocyte values, seven showing a considerable increase and six a decrease in the number of thrombocytes. An increase was observed only when the initial value had been considerably below the average, and a decrease when it had been greatly above the average. Control tests on guinea-pigs produced the same results. The author thinks that the thrombocytosis resulting from medication with vitamin A is due to the fact that the vitamin stimulates the thrombocytopoiesis; the decrease in case of high values results from regulatory mechanisms.

**Juxtapleural Marginal Shadows in Roentgenogram.**—Bennholdt-Thomsen states that he observed juxtapleural marginal shadows in approximately one third of 882 x-ray films of the lungs of diseased and healthy and of tuberculin-positive and tuberculin-negative children. In many instances these marginal shadows had no connection with the pulmonary process. In a number of cases that came up for necropsy, the pleura was entirely free from changes in spite of the fact that roentgenoscopy revealed marginal shadows. Accordingly, the author believes that the marginal shadows may appear in the presence or absence of pathologic processes. In the latter, "normal" cases, the "internal muscle shadow of the thoracic wall" (Knutsson) is the shadow-producing factor. According to Knutsson, the denser marginal zone that surrounds the lung can be explained in the majority of cases as resulting from Mach's optical illusion. The author thinks that further improvements in the technic will show these "normal" juxtapleural marginal shadows with increasingly greater clarity.

**Stearins and Increased Antitoxin Formation.**—Eisler and Gottdenker made experiments with diphtheria toxin and found that under certain conditions it is detoxicated by wool fat and olive oil. They observed that the quantitative conditions and the time factor play a part in producing detoxication. The fact that wool fat and olive oil exert similar actions in this respect suggested to the authors that the presence of stearins in these substances is the cause. Accordingly, they made experiments with cholesterol and found that the addition to toxoid or toxin of quantities of cholesterol which are adequate to effect detoxication increases the antibody formation.

### Sovetskiy Vrachebnyy Zhurnal, Leningrad

Dec 30, 1936 (No. 24) Pp. 1842-1920. Partial Index

**Chlorine Therapy of Infectious Hemorrhagic Colitis.**—Kevdin and Shikh-Mametbekov report sixty-one cases of colitis in which they administered chlorine enemas. With the exception of nine cases of amebic dysentery, they were either acute, of from three to twelve days' duration, or subacute, of from fifteen to twenty days' duration. Nineteen of the patients presented the severe form of hemorrhagic colitis with rise of temperature, intoxication, prostration, insomnia and cardiac weakness. These patients had from thirty to forty bowel move-

ments daily. Eight cases were caused by lamblia, twenty-six by the bacillus of Flexner, six by the bacillus of Shiga, and twelve were of unknown etiology. The enemas consisted of from 600 to 900 cc. of chlorinated water in the concentration of 1:50,000. The chronic amebic cases were not benefited by this therapy. Rapid improvement was observed in thirty-nine of the acute cases. A diminution in the number of bowel movements and disappearance of the blood were noted after the first or second enema. The mucus diminished gradually after an initial increase. From seven to eight daily enemas were sufficient in most of the cases. The authors believe that the effect was probably due to a bactericidal action of the chlorine ions and the liberated oxygen. They consider, however, the question of the mode of action of chlorine unsettled and requiring further study.

### Results of Nephrectomy for Tuberculous Lesion.

According to Gertsenberg, miliary tuberculosis and tuberculous meningitis are the most frequent causes of death after nephrectomy for a tuberculous lesion of the kidney. Of 100 nephrectomies performed at the clinic of Professor Kholstov for a tuberculous disease, ten patients died within six weeks after the operation. All were old, neglected cases. Of the surviving patients, 22 per cent died at a later date. The causes of subsequent death in the order of their frequency were tuberculosis of the remaining kidney, miliary tuberculosis and tuberculous meningitis. There were sixteen deaths among forty-nine men operated on, and ten deaths among fifty-one women operated on. The higher mortality in men is explained by the tuberculous involvement of their sexual organs. The combined mortality, e. g., the immediate and the remote, is about 30 per cent. In patients surviving the two year period, the remaining tuberculous foci become quiescent or undergo a complete cure. The accompanying tuberculous process in the lungs or in the remaining kidney retards the complete cure. The remaining kidney was involved in 14 per cent of their material. Tuberculous disease always begins in one kidney and only after a lapse of some time involves the other. The early operation therefore offers the best chance of a cure. About 70 per cent of all patients operated on survive and about 50 per cent obtain a permanent cure. These results are influenced by the subsequent treatment of other tuberculous lesions present. Patients nephrectomized for a tuberculous lesion should be given, in the author's opinion, from one to two months of climatic sanatorium treatment and should be kept under dispensary supervision for a long time. Child bearing is permissible if the remaining kidney is normal, not earlier however than two or three years after the operation.

### Hospitalstidende, Copenhagen

79: 1317-1336 (Dec. 15) 1936

\*Content of Vitamin C (Cevitamic Acid) in Spinal Fluid: II. Relation to Capillary Resistance and Diet. E. Vestergaard and G. K. Stürup.—p. 1325.

Establishment of Mineral Particles in Sputum of Silicotic Subjects. C. J. Jacobson.—p. 1333.

**Content of Vitamin C in Spinal Fluid.**—Vestergaard and Stürup estimated the cevitic acid content in the cerebrospinal fluid of 101 afebrile psychoneurotic patients by Tillmann's titration method and their capillary resistance by Gothlin's test and obtained as complete a dietary history as possible. No absolute relation was seen between the vitamin C content of the food, its actual content in the cerebrospinal fluid and the capillary resistance. There was some relation between the foods previously ingested and the vitamin C content of the cerebrospinal fluid. In a case of scurvy the cevitic acid content of the cerebrospinal fluid was rather low, but it was lower in many cases without scorbutic or prescorbutic symptoms. When from 100 to 300 mg. of cevitic acid was given by mouth daily, the cevitic acid content of the cerebrospinal fluid always increased and kept the higher level for some time after the medication ended. The capillary resistance remained constant in some cases and decreased in others in spite of the medication. Apparently the addition of fresh vegetable salads to the daily diet raised the vitamin C content of the cerebrospinal fluid. The authors consider it unlikely that vitamin C deficiency is of substantial importance in the development of "spring fever."

assume that the experimental changes resulting from the introduction of Pfeiffer's bacillus into men resemble genuine influenza in only some of their symptoms.

**Trichlorethylene as Skin and Wound Cleanser.**—Trumper and his colleagues state that trichlorethylene has been used as a wound cleanser in twelve chemical factories for three years. In a single year more than 50,000 first aid dressings were carried out in these factories, of which at least one third received preliminary treatment with trichlorethylene. The majority of the wounds have been cuts of the fingers, but trichlorethylene has also been employed for lacerations and burns of other areas. The general principle has been to treat all dirty and greasy wounds with trichlorethylene, irrespective of size or severity. It is applied with a spray, which is held at a distance of from one-half to 2 inches from the wound. The amount used varies according to the size of the wound and the amount of grease. The use of large amounts does not adversely affect the subsequent treatment of the wound. The trichlorethylene dissolves the oil and grease and flows away as a dirty liquid, after which the wound presents a moderately clean appearance. An antiseptic, such as flavine, is then applied and the wound is dressed in a normal manner. Any slight irritation caused by the trichlorethylene is immediately allayed by the application of an antiseptic. The use of trichlorethylene has neither delayed healing nor predisposed to sepsis. The chief precautions to be taken in using the trichlorethylene spray for wounds is to ensure that the ventilation of the room is adequate to prevent any narcotic symptoms arising. It is also advisable to prohibit smoking while the spray is being used, since there is a possibility of injurious decomposition products being inhaled by the smoker.

General Practice: VII. First Six Months. A. H. Douthwaite.—p. 103.

**Treatment of Obesity.**—Coombs and his associates stress the importance of dietetics in the treatment of obesity. Without some control of the diet, all other methods are likely to fail. The few contraindications to treatment by means of dietetic control include extreme old age, acute disease (tonsillitis and rheumatic fever) and severe disease (grave anemia), and when fainting, nervousness, weakness or irritability occurs the treatment should be interrupted for a short period. Medical supervision should be insisted on throughout the entire treatment, and, if possible, for some time afterward so that the patient may be kept at the optimal weight. The scientific principles consist of (1) restriction of carbohydrates, more especially of the concentrated forms such as sugar, bread, potatoes, beer and ginger beer, (2) restriction of fats that do not contain vitamins, (3) very little restriction of proteins, (4) a generous supply of vegetables and fruit to provide bulk and to satisfy hunger, (5) an adequate supply of vitamins by vegetables, fruit, eggs, milk and butter, (6) an adequate supply of minerals by salads and milk and restriction of table salt, (7) no restriction of fluids, (8) bulky meals, to prevent hunger, and (9) three or four meals during the day but nothing between meals. Another fundamental method of attacking obesity is by the inauguration of proper exercise. Patients must be encouraged to increase their activity gradually, and dancing, swimming, walking and golf are particularly to be recommended. Unlike diet and exercise, glandular therapy is not without considerable danger. Thyroid medication often causes addiction and predisposes a patient to thyrotoxicosis and auricular fibrillation. The administration of drugs (nitrophenols) should be used with the greatest caution and only by those fully aware of its dangers. Occasionally surgery is necessary for the removal of fatty tumors, and the surgical removal of adipose tissue in the abdominal region is sometimes undertaken. The adiposity generally does not recur in the same region, but this method of

treatment is illogical and commands no widespread approval. Physical therapy is a useful adjunct to the treatment of many diseases and obesity is no exception, but there is considerable truth in the statement that the only person who loses weight by massage is the masseuse. Baths, diuretics and purging should be employed only under medical supervision. The results of treatment depend a great deal on the education of the patient and the personality of the practitioner. The dangers of obesity should be explained and the rationale of the therapeutic measures given consideration.

**Schistosomiasis and Splenomegaly.**—Campbell has records of something like 200 cases of splenomegaly, in the majority of which the only diagnosis that could be reached was splenic anemia (Banti's disease). From November 1934 to January 1936 operations were performed in thirteen cases with the diagnosis of splenic anemia. The spleen was removed in twelve; it was firmly fixed and irremovable in the other. Liver biopsy was performed in four cases, and, in two other cases in which biopsy was not done, liver was obtained at necropsy. In three of these six livers, the ova of *Schistosoma japonicum* were discovered. Of the splenectomized patients, two died of hemorrhage from the liver or diaphragm, and one died after two weeks from mesenteric thrombosis. Two of the three fatal cases were those with marked ascites. The nine other splenectomized patients were all improved, some of them strikingly so. The belief is expressed that most of the so-called Banti's disease of the Orient is actually schistosomiasis. It is suggested that prior to operation the spleen be vigorously manipulated and a comparison of the platelet count made before and after manipulation, in an effort to recognize those cases which will be complicated by thromboses in the postoperative period. It is suggested that platelet counts be done at operation, and, if the count rises greatly after delivery of the spleen, that the spleen be not removed but the splenic artery merely ligated.

**Acute Meningitis in Early Syphilis.**—Frazier and Mu selected 169 consecutive cases of acute syphilitic meningitis for analysis. The age of the patients ranged from 18 to 58 years, 50 per cent falling within the third decade of life and 35 per cent within the fourth decade. The most striking clinical characteristic of the meningeal syndrome in the series was paralysis of one or more cranial nerves, an indication of a predominating localization of the disease in the basal meninges of the brain. There were 119 cases of basilar meningitis, twenty of acute hydrocephalus, nineteen of diffuse cerebral meningitis and eleven of spinal meningitis. Cranial nerve palsy was the most frequent single abnormality, occurring in 162 patients. With the exception of the eighth nerve, paralysis of a single nerve occurred but rarely. The eighth nerve was affected in 122 of the patients. There were fifty-five instances of unilateral involvement and sixty-seven of bilateral involvement. In forty-six individuals this was the only nerve paralyzed. As a rule both cochlear and vestibular branches were affected. As loss of function of the vestibular branch is soon compensated, impairment of hearing was the only symptom giving the patient much trouble. In many of the treated patients evidence of relapse was not limited to the central nervous system. There were twenty-four instances of delayed or relapsing secondaries of the skin and mucous membranes, which included most of the erup-

counted as severe cases, were admitted to the hospital, and are included in the present study of fifty selected cases of severe endemic pellagra.

The three patients with pellagra secondary to chronic alcoholic addiction were sent to private physicians, who treated them successfully by the methods described in this paper. Since the disease in these three persons was accompanied by chronic alcoholism, these cases are not included in the present series.

In order that our responsibility might best be fulfilled toward the fifty patients with severe endemic pellagra, forty-seven were admitted to the Hillman

Birmingham. A number of the patients were shown at this meeting, discussion and criticism being welcomed. No dissenting opinion concerning the methods of selection or diagnosis of cases was offered.

At all times the authors assumed the full responsibility for the treatment of these patients. The present report deals only with the fifty patients with severe endemic pellagra admitted to the hospital for study and treatment.

*Method of Clinical Study.*—When obtainable, the following data on each of the fifty patients were recorded: race, sex, age, presence or absence of dermatitis, glossitis, stomatitis, peripheral neuritis, loss of weight or strength, elevation in pulse rate, previous attacks of the disease, and the presence of other diseases. Special studies concerning the quantity and

perculous meningitis due to reactivation of a latent tuberculosis. These were the only two cases that ended fatally. As long as no specific germ has been discovered, erythema nodosum may be looked on as the response of an allergic constitution. It is the sensitivity of the skin which causes the appearance of the nodule. No specific treatment exists. A number of stimulating remedies are mentioned, also change of climate.

**Extracardiac Murmurs in Patients with Pulmonary Tuberculosis.** H. Descomps.—p. 1690.

**Extracardiac Murmurs.**—Descomps was impressed by an intense murmur at the level of the pulmonary artery accompanied by a displacement of the heart to the left. Under the fluoroscope this seemed to modify the left hilus. These murmurs appear at the second or third intercostal space and are palpated as a true fremitus. The systolic murmur is prolonged at the pulmonary atrium, soft or at times sharp, becoming weaker from within outward. It varies with the position of the patient and the number of respirations, or from day to day. The functional disorders are palpitations, extrasystoles and some dyspnea. These extracardiac murmurs are found mostly in women, young girls or children, and exceptionally in men. The roentgenograms of all these patients show parenchymatous and lymph node lesions situated against the aortic arch in left-sided murmurs, and in the upper hilus in right-sided murmurs. The opacity of the heart may sometimes obscure the view. The fluoroscope shows it nicely in expiration when viewed in motion laterally. A comparison with true mitrocardiac syndromes suggests itself to the author. He is also impressed with their absence in adult men. The article is accompanied by five roentgenograms containing drawings to demonstrate the lesions.

**Acid Milk in Diet of Infants.**—Rohmer and Chapelo state that acidification of milk promotes gastric digestion. By dint of its wealth in buffer substances, cow's milk absorbs three times as much hydrochloric acid as human milk. From this it may be deduced that it is of greater advantage to employ acid milk without overcharging the secretory functions. In cases of undernourishment the functions of the stomach are diminished and it is reasonable to give to the infant the kind of nourishment that will necessitate the least effort. Acidification causes a fine flocculation of the casein, which increases its digestibility. Small quantities of lactic acid increase metabolism. Acidity also controls the development of colon bacilli. Nearly all authors recommend whole milk acidified and prepared with flour and sugar. It is nourishing and well tolerated by children and infants and by premature babies or debilitated children. It has antidyseptic properties and is given, whole or diluted, even in cholera. Objections came from Bessau, Rominger and others, who contend that whole milk is antipathologic for the infant, gives rise to rickets and diminishes resistance against infections, that its great richness leads to overnourishment and that it may be accepted when prescribed by a physician, but not as a routine feeding. In the face of these contradictions the authors have decided to resume the research on acid milk. It is not their intention to use it as

a substitute for other alimentary methods that have proved their value. As the quantity to be taken by the infant is much smaller than what the infant is in the habit of taking, it should be used only under the strict supervision of the doctor in order to avoid overnourishment. After proving its digestibility and its wealth in calories and in building materials, the authors point out its indications: 1. In mixed feedings and in cases of total weaning of infants less than 2 months of age. Also in premature and debilitated infants. 2. In feeding emaciated infants who are urgently in need of special nourishment. Its constipating properties could be utilized in dyspeptic conditions, notably in chronic dyspepsias, especially when they have been brought about by infections. It will render profitable service as a prophylactic in these conditions in an effort to overcome secondary dyspepsias. It has some similarities with albuminous milk and as such it could be profitably prescribed in abdominal disorders.

**Bone Metastases from Hypernephroma; Roentgen Treatment: Case.** G. De Luca.—p. 453.

**Motility of Gallbladder and Visibility of Excretory Bile Ducts.**—Roncoroni studied the functions of the gallbladder by cholecystography. The normal gallbladder can be seen within the first hour of the injection of the opaque substance. The maximal opacification of the gallbladder takes place within eight hours of the injection. It is related to the tonus of the structure and coincides with the final phase of evacuation of bile. Elimination of the opaque substance does not take place spontaneously, but only after administration of a fat meal (two egg yolks in milk). Normal evacuation takes place within sixty minutes after a fat meal. The conception of a passive evacuation of the gallbladder, caused by duodenal suction or by a mechanism of siphonage of the bile from the hepatic duct, is erroneous. Gallbladder evacuation is an active phenomenon due to muscular contraction of the structure. It originates in a nervous reflex which simultaneously opens Oddi's sphincter and increases the tonus of the gallbladder with consequent contraction of the structure. This statement is proved by the passive behavior of the cystic and common bile ducts throughout the contraction and evacuation of the gallbladder and by the reflux of bile, which can be seen in the last segment of the hepatic duct when the excretory ducts are visualized by cholecystography. According to the author, the excretory functions of the gallbladder are controlled by Oddi's sphincter on the one hand and by functional nodes (not sphincters) placed at the openings of the gallbladder into the cystic duct and of the hepatic duct into the common bile duct. Visibility of the excretory ducts depends on the opacity of the gallbladder, is related to the tonus of Oddi's sphincter and is of diagnostic significance. Clear visibility of the cystic and common bile ducts indicates diminished tonus of Oddi's sphincter, whereas that of the hepatic duct indicates increased tonus of Oddi's sphincter. The results of cholecystography agree with those of duodenal soundings, after duodenal injection of magnesium sulfate.

**Pathogenesis of Recurrent and Chronic Infection of Rhinopharynx and Desensitization by Vaccines.** V. Rossi.—p. 812.

**Uric Acid Elimination Test for Renal Functions.**—Stefanini made determinations of the elimination of uric acid during the concentration and dilution tests (Volhard) and after administration of an intravenous injection of 0.05 Gm. of sodium nucleinate for renal function. The tests were made in children convalescing from renal diseases and, for control, in

but, irrespective of this, the patients were forced to take additional amounts of food to make up for the loss through diarrhea. Some of the patients seemed to be relieved from diarrhea by the administration of tincture of opium in doses of 2 cc. until 10 cc. a day had been given or until signs of toxicity appeared. In the cases of severe dehydration, parenteral injections of saline solution were given.

**Abdominal Pain:** Most of the patients had abdominal pain soon after eating. Tincture of opium, 2 cc., was used to alleviate this pain when an analgesic was required.

**Anemia:** Four patients having dyspnea and a hemoglobin value below 50 per cent were benefited by blood transfusions.

**Fever:** Patients with temperature elevations were bathed with alcohol, and their general condition was thereby improved for a short time.

**Tachycardia:** Patients with tachycardia were kept in bed until the heart rate was normal. When they were first allowed to get up, they were watched carefully for symptoms of vasomotor collapse.

**Mental Symptoms:** Large doses of bromide and barbitol were administered to the maniacal type of

remaining three died, but at the time of death each showed healed or healing pellagrous lesions.

Recovery was rapid in the forty-seven cases in which there was remission of the disease. Within twenty-four hours after treatment was initiated, the oral and dermal lesions began to heal and the patients' sense of well being improved remarkably. The average number of days in the hospital for these forty-seven patients was nine. The fifty patients included twenty-one males, nineteen white and two colored, and twenty-nine females, nineteen white and ten colored. The average age was 43 years. The age, sex, race of the patient or the occurrence of previous attacks of the disease did not affect the rate of recovery, as shown in the table.

Studies in each of the fifty cases showed that all the patients had a loss of strength, forty-one had pellagrous glossitis, thirty-three pellagrous stomatitis, forty-eight pellagrous dermatitis, twenty-eight vomiting, twenty-nine diarrhea, twenty-seven mental symptoms, thirty-one peripheral neuritis, forty-nine loss of weight (in the other patient the loss of weight, if any, could not be determined because of edema) and thirty-one had had previous attacks of pellagra. Thirty-nine out of forty-nine had an elevation in pulse rate on more than two occasions; twenty of the thirty-three patients examined had an anemia, and fifteen of the thirty-eight patients examined had achylia gastrica following histamine injection. Fifteen of the fifty patients had an organic disease other than pellagra. Five had heart disease, three intestinal stricture, two pulmonary tuberculosis, two diabetes, two pulmonary infarction and one nontuberculous respiratory infection.

As has already been stated, three of the patients died. Postmortem studies were made by Dr. Benjamin Morton and Dr. G. S. Graham. Brief summaries of the clinical course and pathologic changes in these three cases are given:

**CASE 1.**—V. O., a colored woman, aged 33, was well until July 1935, when she developed pain in the lower part of the abdomen. In September 1935 she had an operation for ovarian tumor and at the end of two weeks was discharged from the hospital. A month after the operation was performed, a large fistulous opening appeared in the abdominal incision. From that time on the patient passed large amounts of liquid fecal material through the fistula, but she rarely passed any material by rectum. She became weaker steadily and her family noticed that she was losing weight. March 3, 1936, she was admitted in a dying condition to the surgical service of the Hillman Hospital. She was unable to talk coherently and was emaciated to a degree rarely seen. Her pulse was weak, rapid and thready. Bilaterally symmetrical areas of pellagrous dermatitis were observed over her face, arms, legs and body. Severe pellagrous stomatitis, glossitis and vaginitis were also present. Immediate symptomatic and antipellagric therapy was initiated, and within forty-eight hours the pellagrous lesions were healing. They continued to heal until the time of her sudden death on the fourteenth day of hospitalization.

Postmortem examination showed healed and healing pellagrous lesions, a large ball-valve clot in the right auricle, and a large hard and well formed pulmonary embolus occluding one of the main branches of the pulmonary artery. The fistulous opening was about 3.5 cm. in diameter and connected the mid-portion of the ileum with the old abdominal scar.

**CASE 2.**—E. H., a colored woman, aged 26, was in good health until November 1934, when she passed large amounts of blood by rectum. From that time on she found it necessary to take large doses of laxative, and even then her stools were never as large as a lead pencil. Soon afterward she stopped eating solid food because of the abdominal pain that invariably followed. During February 1936 her mouth and tongue became sore, and a dermatitis appeared over the dorsum of her hands

DIET 4.—Diet Recommended After Discharge

Food	Amount
Sweet milk.....	1 quart
Eggs.....	4
Lean meat.....	¼ to ½ pound
Vegetables: potatoes, butter beans, black-eyed peas and navy beans.....	2 servings
Other vegetables: spinach, greens, carrots, beets, tomatoes, cabbage, English peas or any other vegetable.....	2 servings
Fruit, any kind.....	1 or 2 servings
Bread, any kind.....	6 slices; 2 slices of corn bread may be used in place of white or whole wheat bread
Cereal, any kind.....	large serving

patient, but care was taken not to render the patients stuporous over long periods of time.

**Peripheral Neuritis:** Sedatives and analgesics were often required to relieve the pain so that the patients could sleep. Some of the milder cases were aided either by ice bags or 1 per cent phenol and menthol applied over areas of hyperesthesia.

**Decubitus:** Decubitus was prevented by conscientious nursing care.

**Recommended Therapy After Discharge.**—On discharge from the hospital, all patients were instructed to take the prescribed amount of a highly nutritious diet each day at home (diet 4). This diet consists of 1,950 calories and contains 104 Gm. of protein. Each person was allowed to eat additional amounts of any of these foods if he wished and was permitted to eat other foods after he had eaten the full amount of the prescribed diet. Food was purchased until June 10 for many of the patients who could not afford to buy the required amounts. All patients were seen frequently in their homes following discharge from the hospital. Three of the fifty had a definite relapse of their disease within a month, although they claimed that they had followed the prescribed diet carefully. These three patients were readmitted to the hospital for special study, the results of which will be reported at a future date.

#### OBSERVATIONS

Forty-seven of fifty patients admitted to the hospital with severe endemic pellagra improved and were discharged to their homes free from symptoms. The

cold granulitis. The patient was suffering from fibrocasseous tuberculosis and had recently had several small hemoptyses. Administration of gold treatment and complete rest induced disappearance of the granulations from the lung roentgenograms in a few weeks.

### Semana Médica, Buenos Aires

44: 81-160 (Jan. 14) 1937. Partial Index

- Total Left Pneumectomy: Case. J. Arce.—p. 81.

 Sexual Activity in Infant: Case. O. J. Marchilli and J. F. Capelli.—p. 140.

**Salicylic Poisoning in Children.**—De Alzaga says that rheumatic fever with its consequent cardiac complications is frequent. Sodium salicylate is the specific remedy. The author administers it by mouth or by rectum in doses corresponding to 1 Gm. of salicylate for each year of age and with it a double amount of sodium bicarbonate. In grave cases, besides the doses given by mouth or rectum, the patient is given one or two daily injections of from 0.5 to 1 Gm. of sodium salicylate in 10 cc. of a 10 per cent solution of dextrose to which 0.01 Gm. of caffeine is added. Sodium salicylate prevents relapses and sometimes, when given to a patient at rest and in combination with certain hygienic habits, it induces attenuation and disappearance of official murmurs. The treatment fails only in grave forms of the disease or in cases of febrile asystole. Salicylic intoxication due to intolerance is rare. Intolerance has nothing to do with the route of administration (oral, rectal or intravenous) of the drug. It is due primarily to hepatic or renal insufficiency. The author reports a case of acute intoxication in which the patient, aged 6 years, reached a state of coma. In two days the patient had received (by mouth and rectum) 14 Gm. of salicylate, which had been administered in association with sodium bicarbonate. The most serious symptoms were renal, nervous and toxic (oliguria, albuminuria, diminished diuresis, delirium, somnolence which reached coma, vomiting, deafness and toxic dyspnea). Repeated epistaxes were observed as an uncommon symptom. The treatment was symptomatic and urgent. It consisted in administration of dextrose solution, insulin and fruits. The patient recovered.

**Diathermic Coagulation in Chronic Cervicitis.**—Herrera and Nogués point out the possible complications of diathermic coagulation in chronic cervicitis. The most serious complications may be immediate or late hemorrhages, pelvic inflammation, obturation of the external orifice of the neck of the uterus by membrane formation, and cicatricial stenosis of the cervical canal. The latter may result in the formation of hematometra, hematosalpinx and hematocele as the result of retention of menstrual blood and, later on, of pyometra, pyosalpinx and pelvi-peritonitis and peritonitis by complications or infections. The authors report several cases of complications and advise, first, limitation of diathermic coagulation to proper indications and, secondly, administration of diathermic coagulation by specialists and not by general practitioners. Specialists should decide on the indications and opportunity of administering diathermic coagulation and should make an early diagnosis and give an early treatment if complications develop.

**Dilution and Concentration Test in Pregnancy.**—León and Torre found that in normal pregnancy as well as in pregnancy complicated by edema or simple albuminuria the polyuria induced by the dilution and concentration test (Volhard) is retarded and diminished in comparison to that in normal women. The concentration power of the kidney is normal, which shows that insufficient elimination of urine originates in extrarenal disturbances of the water metabolism. In pregnant women suffering from pyelonephritis or glomerulonephrosis, induced polyuria is greatly diminished and the concentration capacity of the kidney is defective. In normal puerperium the elimination of urine is abundant, even if the test is made at the time of appearance of milk secretion. As the date of delivery passes, the results of the test approach more those obtained in normal

women. In puerperal women who suffered from glomerulonephritis during pregnancy or from eclampsia, the results of the test show an insufficiency in the dilution and concentration test. The disturbances of elimination of urine in these cases demonstrate insufficiency of the secretory functions of the kidney.

 Millary Tuberculosis and Vascular Focus. P. Huebschmann.—p. 773.

**Subpleural Nodules and Pulmonary Tuberculosis.**—Warcalde cites studies of Anders and Schmoe on the significance of the tuberculous infection of subpleural lymph nodes for the development of pulmonary tuberculosis. These authors assumed that the nodule-like foci under the pleura correspond to the subpleural lymph nodes and concluded that these nodules play an important part in the pathogenesis of tuberculosis. These conclusions induced the author to study the subpleural nodules. His material consisted of thirty-eight cases in which tuberculosis had not been the cause of death. In order to detect the subpleural nodules, he resorted to inspection and bimanual palpation of the lungs. He never was able to detect subpleural nodules in patients who were less than 30 years of age, but in thirty-eight cases of the higher age groups he found such nodules. He used a combined elastica-van Gieson stain and describes his observations on the various types of nodules. He found caseated tuberculous nodules and elastic fibers in four cases, connective tissue or cicatricial nodules with tuberculous changes in the surrounding pulmonary tissue in three, connective tissue nodules with elastic fibers in three, nodules with a connective tissue capsule and caseated contents in one, nodules with lymph tissue in two, nodules consisting entirely of connective tissue or cicatricial tissue in twenty-three and nodules with tumor metastases in two. The author admits that, in view of the fact that the lungs were not examined by means of serial sections, these observations do not justify a definite estimation of the conclusions reached by Anders and Schmoe. However, he thinks that one point is definitely proved by his observations; namely, that some of the subpleural nodules do not correspond to the subpleural lymph nodes. He is convinced that in seven of the foregoing cases the nodules correspond to tuberculous foci in the lung tissue, most likely small primary foci. If this is so it may also be doubted whether the majority of the other nodules are diseased lymph tissue. Moreover, it is noteworthy that tuberculous changes were absent in the two cases in which lymphatic tissues were found in the nodules. The author doubts that the far reaching conclusions of Anders and Schmoe regarding the significance of the pathogenesis of tuberculosis are justified. To be sure, he does not feel qualified to make a definite statement as to the significance of the subpleural nodules, realizing that further studies will be necessary, but he is convinced that their importance for the pathogenesis of pulmonary tuberculosis is slight.

## DERMATOLOGIC VERSUS SURGICAL TREATMENT OF CARBUNCLES AND FURUNCLES

SAMUEL AYRES JR., M.D.  
NELSON PAUL ANDERSON, M.D.  
AND  
PAUL D. FOSTER, M.D.  
LOS ANGELES

In view of the fact that carbuncles and furuncles are such relatively common and well understood conditions, it is surprising that diametrically opposed methods of treatment are practiced. The incident which inspired this investigation was the demonstration of a patient by a surgeon at a hospital staff meeting. The case was presented to illustrate a successful and satisfactory outcome of the treatment of a carbuncle of the side of the face. The patient was alive, it is true, but his face was disfigured by an extensive crucial incision scar covering almost the whole side of the face. One of the authors who attended the staff meeting expressed the opinion that if a dermatologist had achieved such a result as the consequence of treating a carbuncle he would have preferred keeping the patient hidden rather than presenting him as an outcome to be proud of.

We have never found it necessary to resort to radical methods in the handling of carbuncles, yet conversation with surgical colleagues has disclosed that crucial incisions or radical cautery excisions are the rule. At the Los Angeles County General Hospital all carbuncle cases are admitted to the surgical service and the great majority of them are treated by radical methods.

In order to ascertain the accepted methods of treating carbuncles and facial furuncles, approximately 500 questionnaires were mailed to an equal number of representative dermatologists and surgeons in all parts of the country. A tabulation of the results of these questionnaires revealed the fact that dermatologists tend toward conservatism in the treatment of carbuncles, whereas surgeons are more inclined to use radical procedures. Both dermatologists and surgeons usually practice conservatism in the treatment of early facial furuncles.

The etiology and histology of the furuncle and carbuncle are so elementary that the barest outline will suffice to bring out the salient points. The furuncle is an external infection by a staphylococcus that has gained entrance to a hair follicle. An inflammatory reaction is set up along the whole length of the hair follicle. A densely packed zone of leukocytes appears at the center of the process. About these a walling off zone of fibroblasts appears, beyond this a loosely packed zone of leukocytes and fibroblasts and beyond this a zone of hyperemia. Usually the central portion of this concentric pattern undergoes necrosis and pus appears. Under ordinary conditions the pus makes its way to the surface along the hair follicle following the line of least resistance and appears at the surface of the skin as the yellow "head" of the boil. Sometimes, however, if the infection is especially virulent or the resistance of the patient is low, the infection extends deeply into the subcutaneous tissue along the columnae adiposae, spreading laterally along the panniculi adiposi and rising toward the surface along adjacent hair follicles, thus producing a large inflammatory area with multiple

"heads" or a carbuncle. A carbuncle may range in size from that of a silver quarter (24 mm.) up to that of an adult hand or larger. Diabetes predisposes to large and extensive lesions.

The surgeon's traditional approach to this problem in the carbuncle stage is radical, usually consisting of an extensive crucial incision over the involved area and undercutting the flaps, or excising the whole area with the knife or the cautery, in either case attempting to remove the entire diseased area. With skilful technic the desired result is usually achieved, although the period of convalescence is likely to be long and the cosmetic end result is usually unsightly and in certain locations may be actually disfiguring.

The dermatologist approaches the treatment of a carbuncle from an entirely different point of view. Three considerations guide his treatment:

1. Arrest of the disease process.
2. A short convalescence.
3. A good cosmetic result.

If arresting the disease process were the only consideration, total excision or cautery destruction would undoubtedly achieve that end most rapidly. The most rapid method of destroying the diseased area, however, is often followed by a much slower period of healing and a bad cosmetic result. Except in most unusual circumstances, a slightly slower method of arresting the infection is not inimical to the welfare of the patient. In fact, the questionnaires show a lower mortality rate among cases treated by dermatologists using conservative methods than among those treated by surgeons using radical methods. One must evaluate this in the definition of carbuncles and in the difference in degree of severity of those treated by surgeons and by dermatologists.

Furuncles and carbuncles of the face, especially within the so-called dangerous circle, are considered much more serious than those occurring elsewhere, although we ourselves have never observed any serious complications in patients with lesions in this area. The reason for occasional fatalities resulting from carbuncles or furuncles within the "dangerous circle" is that a septic thrombophlebitis may develop in the angular vein extending to the cavernous sinus, or if on the lower part of the face the thrombophlebitis may extend downward into the external jugular vein.

For this reason it is generally agreed by surgeons and dermatologists alike that deep incision, squeezing or other manipulations should be avoided in the treatment of early carbuncles or furuncles of this area. If pus appears at the surface, it may be evacuated by lightly pricking the lesion. If the lesions show evidence of extension, and especially if fever and other symptoms suggest the development of thrombophlebitis, surgeons advocate interception of the process by ligating or cauterizing the angular vein near the bridge of the nose or the anterior facial vein near the jaw.

### SUMMARY OF STATISTICS FROM QUESTIONNAIRES

The accompanying table summarizes the statistics contained in the questionnaires. Since answers to some of the questions were in round numbers, and the treatment of carbuncles and furuncles was not clearly differentiated in many cases, the figures are to be regarded as approximate. Unfortunately the question regarding cosmetic results was not answered in a sufficient number of cases to afford any basis for comparison. Without exception, dermatologists who answered this question reported good cosmetic results in cases treated conserva-

## SEVERE ENDEMIC PELLAGRA

A CLINICAL STUDY OF FIFTY CASES WITH SPECIAL  
EMPHASIS ON THERAPY

TOM D. SPIES, M.D.  
CINCINNATI

AUSTIN B. CHINN, M.D.  
WASHINGTON, D. C.

AND  
JAMES B. MCLESTER, M.D.  
BIRMINGHAM, ALA.

The pellagra of the northern part of the United States is for the most part associated with chronic alcoholism, whereas that found in the Southern states usually is not. Even though observations<sup>1</sup> on large numbers of pellagrins have shown that both the endemic and so-called alcoholic types usually have a predisposing dietary insufficiency, the same seasonal occurrence, the same symptomatology and similar lesions, there is still controversy as to whether the two are the same disease. Previous studies showed that the mortality rate among patients with severe pellagra, the majority of whom were addicted to alcohol, could be reduced from 54 per cent to 6 per cent in a series of 125 cases.<sup>2</sup> The death rate from severe endemic pellagra, however, has remained high, irrespective of the method of treatment.<sup>3</sup> Since endemic pellagra and the pellagra associated with chronic alcoholic addiction are clinically indistinguishable, and since the mortality rate among patients with severe endemic pellagra is high, it seemed imperative that we should apply to patients with endemic pellagra those methods of treatment which had lowered the death rate significantly among the so-called alcoholic pellagrins. Such a study is presented in this communication.

### MATERIAL AND METHODS

It was decided before undertaking the present study that beginning March 1, 1936, fifty consecutive cases of

severe endemic pellagra would be admitted either to the Hillman or to the T. C. I. Hospital<sup>4</sup> for treatment.

*Selection of Cases.*—Pellagra was diagnosed by the presence of characteristic skin and oral lesions. The disease was considered severe if, in addition to a poor general condition, the pellagrin had one or more of the following manifestations of pellagra: mental symptoms, persistent vomiting, intractable diarrhea, an inexplicable elevation in temperature to more than 102 F., a heart rate of more than 120 with the patient at rest, or stomatitis so severe that the patient did not want to eat. The disease was considered mild if the pellagrin's general condition was good and if he had none of the ominous manifestations of pellagra mentioned. No pellagrin was excluded from the study because of the presence of a coexisting disease.

The selection of the fifty severe endemic cases for the present study was made from a total number of 696 persons suspected of having pellagra. These persons either came of their own accord to the Hillman Hospital for treatment or were referred by the physicians of Jefferson County, by the Red Cross authorities, or by the public health departments of Birmingham and Jefferson County. The initial examination of the 696 pellagra suspects showed that 568 had no physical signs diagnostic of acute pellagra (many did have symptoms suggestive of the disease and residual dermal changes from previous attacks), ninety had mild pellagra, three persons with severe alcoholic addiction had severe "alcoholic pellagra," and thirty-five had severe endemic pellagra.

After the initial examination, the 568 persons with no evidence of acute pellagra were told to return to the referring physician or organization. So far as could be ascertained, none of these patients developed manifestations of acute pellagra from the time they were seen by us until June 15, 1936 (the termination of the study). Responsibility was immediately assumed for all persons on whom a diagnosis of pellagra had been made. Accordingly, the ninety patients with mild pellagra were advised to return to their homes and take yeast and a highly nutritious diet rich in milk, eggs, vegetables and protein and were told to return to the hospital for observation at stated intervals. Seventy-five of the ninety patients with mild pellagra improved. The remaining fifteen either could not or would not follow recommendations and the disease became worse. The fact that these fifteen patients formerly having mild pellagra later had the disease in a severe form means that the disease became worse and not that the original interpretation was incorrect. After the development of the severe manifestations these fifteen were

This study was conceived by Dr. M. A. Blankenhorn, Dr. James S. McLester and Dr. Joseph T. Wearn. The professional and administrative responsibilities of organizing and carrying out the study were assumed by Dr. R. H. Bishop Jr., Dr. Blankenhorn, Dr. Alfred Friedlander, Dr. McLester and Dr. Wearn. The project was a cooperative one between the University Hospitals of Cleveland, the College of Medicine of the University of Cincinnati, the University of Alabama, the Hillman Hospital of Birmingham, Ala., and the Tennessee Coal, Iron and Railway Hospital (T. C. I. Hospital) of Ensley, Ala. Financial grants were obtained through the University Hospitals of Cleveland and through the May Fund of the School of Medicine of the University of Cincinnati. The investigation was conducted by the authors, who were assisted by Miss Jean Grant, dietitian, and Miss Ann Van Blaricom, nurse. The professional and administrative staffs of the Hillman and T. C. I. hospitals gave invaluable aid in the selection and care of the fifty patients admitted to the hospital.

be sought out and treated. Dietary indiscretions should be corrected and an adequate vitamin intake assured. In our experience the use of yeast or tin preparations has not proved efficacious. Manganese has had a recent vogue, but we have had no experience with it.

#### SUMMARY

1. Questionnaires were mailed to approximately 250 surgeons and an equal number of dermatologists throughout the United States and Canada in an effort to appraise the methods employed in the treatment of carbuncles and facial furuncles.

2. The information obtained from the questionnaires corroborates our own experience in the treatment of these conditions and may be stated briefly as follows:

3. The great majority of surgeons employ crucial incisions or cautery excision of carbuncles, whereas the great majority of dermatologists employ conservative methods, including x-rays, vaccines, bacteriophage and topical applications.

4. The average duration of treatment of carbuncles under surgical treatment is almost twice as long as under dermatologic treatment.

5. The mortality from carbuncles is low in both groups, but it is more than three times as great under surgical as under dermatologic treatment.

6. Cosmetic results in our experience are infinitely superior under the conservative methods used by dermatologists as compared with the radical surgical procedures.

2007 Wilshire Boulevard.

### PREVENTION OF GOITER IN MICHIGAN AND OHIO

O. P. KIMBALL, M.D.  
CLEVELAND

The Michigan State Department of Health made a survey of representative sections of the state in 1923 to determine (1) the incidence of goiter among school children and (2) the amount of iodine in the water supply of each section. Naturally the amount of iodine in the water supply is the best index to the food iodine found in that section. Early in 1924 a program of goiter prevention was outlined. This original program emphasized the importance of a complete resurvey of the same areas in ten years.

The results of the first survey showed beyond a doubt that there is a correlation between a scarcity of food iodine and a high incidence of simple goiter. These data are given here only graphically to recall the areas examined, the incidence of goiter and the amount of iodine in the water supply (fig. 1). From this study it is apparent that the incidence of goiter in any county is inversely proportional to the iodine content of the water supply.

Immediately following this survey a state-wide campaign by the state department of health was made to emphasize the fundamental causes of endemic goiter and the principles of its prevention. In the spring of 1924 a special committee was appointed by the state medical society to work with the state department of health in carrying out this work. These two groups, representing the medical profession of the state, cooperated with the Wholesale Grocers' Association and the Salt Manufacturers' Association to the effect that, beginning May 1, 1924, the salt manufacturers produced and put on the market throughout Michigan an

iodized salt containing one part of potassium iodide to 5,000 parts of salt. The wholesale grocers did everything they could to bring about the sale of this salt only, and the state department of health was responsible for advising the public to use it.

The fact should be reemphasized that there was no law compelling people to use iodized salt—only education and advice in the form of news articles throughout the state, health talks to school children and parents and placards to be used in the schools as in any other health program. All this information and advice was given by the state department of health and the state medical society.

The Ohio State Department of Health in 1925 made a rather comprehensive study of the incidence of goiter throughout the state and planned to support the general use of iodized salt. Six counties were selected as representative of average conditions in Ohio, and during October and November approximately 60,000 school children were examined for goiter. The results of this survey were never published and, because of active opposition to this method of prophylaxis by some of the leading goiter surgeons, the state department immediately withdrew its support and has since shown no active interest in this public health measure.

The study outlined by the Michigan State Department of Health in 1928 again had two objectives: (1) the efficiency of the method of prevention (the general use of iodized salt) and (2) the safety of this so-called indiscriminate use of iodine. The second objective was necessary because of published reports of cases of hyperthyroidism due to the use of iodized salt. To answer this question with scientific data we arranged for a comprehensive study of all adults with goiter in three counties. This study was made by the local medical society with the cooperation of the state department of health. The summary of the results of prevention given in figure 2 shows a marked decrease in goiter in every section. Also the conclusion as to the possibility of harm by the general use of iodized salt was equally definite. We studied 1,229 adults with goiter or patients who had recently been operated on for a toxic goiter in the three counties. Of 655 who had used iodized salt continuously for four years, twenty-seven, or 4.1 per cent, developed symptoms of toxic goiter after using iodized salt. There were 419 who had purposely avoided iodized salt and of this number 233, or 55.5 per cent, developed toxic goiter. After four years of the general use of iodized salt we found it an efficient as well as a safe method of prevention.

McClure<sup>1</sup> found a gradual decrease in the number of goiter operations throughout the state from 1926 to 1932. This decrease was very noticeable, yet there was a gradual yearly increase in the total number of operations.

For practical reasons the ten year resurvey in Michigan could not be made in 1934 but was made in 1935. In order to make our results comparable with the results in 1924 the committee for the prevention of goiter arranged for me to make this survey with the assistance of three physicians from the state department of health and one from the University of Michigan. The goiter committee is composed of two men from the state medical society, two from the state department of health and one from the state university.

1. McClure, R. D.: Thyroid Surgery as Affected by the Generalized Use of Iodized Salt in an Endemic Goiter Region, *Ann. Surg.* 100:924 (Nov.) 1934.

quality of the food eaten by these patients in their homes prior to admission to the hospital were made and will be reported in a separate communication.

A patient was arbitrarily considered as having an anemia if the hemoglobin value on repeated examination was less than 70 per cent. He was considered as having tachycardia if the heart rate was 90 or above on two or more examinations when the patient was at rest in bed. Previous attacks of pellagra were counted as such only if a diagnosis of pellagra had been made by a physician at the time. The presence of other diseases was determined by clinical and laboratory examinations.

**Method of Treatment.**—Each of the fifty pellagrins was treated individually and was given adequate professional and nursing care in order that the general and specific therapeutic measures might be effectively applied. After the diagnosis of severe endemic pellagra had been made, each pellagrin was admitted to the ward, confined to bed, and given antipellagric therapy immediately. In order to keep the patients alive, it was also necessary, in certain instances, to give prompt supportive treatment to those who were at the point of death and to apply specific therapeutic measures to those with coexisting organic diseases.

**General Therapeutic Measures.**—All patients were kept in bed until convalescence was well established. At times this was accomplished only after large doses of sedatives had been administered. Constant nursing care was given to conserve the patient's strength, to assure adequate rest, to give the specific and symptomatic therapeutic materials, and to aid in applying suitable dietary measures. An effort was made to give each pellagrin a well balanced diet of 4,500 calories or more each day. Every detail of the intake of food was supervised to make certain that an adequate diet was ingested and retained daily. When large amounts of food were lost because of vomiting or diarrhea, corresponding additional amounts were given.

**Dietary Management.**—In order to make sure that each pellagrin received and retained as much food as possible, he was urged by the physicians, nurses and dietitian to eat one of three diets each of which was high in calories and rich in protein. Every effort was made to see that the patients took as much solid food as possible. Therefore, at the time of admission, a "solid" diet (diet 1) was prescribed for every pellagrin. When a patient could not continue to eat it, he was given a "soft-solid" diet (diet 2) until he had improved sufficiently to eat the "solid" diet. Those unable to eat either the "solid" or "soft-solid" diet were administered a "liquid" diet (diet 3) until they could eat the "soft-solid" diet. Twenty-seven of the fifty patients continued to eat the foods in diet 1 from the time they were admitted to the hospital until the day of discharge. Seventeen of the twenty-three patients who could not eat the diet were given the "soft-solid" diet for their first three days in the hospital and were then continued on the "solid" diet throughout the remainder of their hospitalization. The remaining six patients ingested the "liquid" diet for from forty-eight to seventy-two hours before they improved sufficiently to take the "soft-solid" diet. By the eighth day of hospitalization, all six were able to eat the "solid" diet.

**Specific Therapeutic Agents.**—All patients were given from 180 to 270 Gm. of powdered brewers' yeast<sup>5</sup> daily. They tolerated this best when it was

given in doses of about 20 Gm. in iced milk. Four patients with severe glossitis, diarrhea and vomiting were given intravenous liver extract<sup>6</sup> injections of 20 cc. each from four to five times a day in addition to the yeast. These injections were continued until improvement took place (usually two or three days).

### Method of Making Yeast Mixture and Eggnog

#### Yeast Mixture

Materials: 600 cc. of milk; 90 Gm. of yeast

Method: Pour milk into a mixing bowl. Put the yeast in a shaker and sift it into the milk, stirring constantly

#### Eggnog

Materials: 3 eggs, 15 Gm. of sugar, 600 cc. of milk

Method: Beat eggs, add sugar, add milk, beat well. If desired, flavor with vanilla

**Special Treatment of Symptoms.**—Skin Lesions: The application of potassium permanganate solution (1:5,000) to the moist type of pellagrous dermatitis often gave relief from the burning sensations and diminished the number of secondary infections.

Diarrhea: As a rule, pellagrous diarrhea ceased only when the pellagra had improved. The number and the amount of the stools were often increased following the administration of large amounts of yeast or food

5. Supplied by Dr. I. F. Harris, Tuckahoe, New York.

6. Furnished through the courtesy of Dr. E. A. Sharp, Parke, Davis & Co., Detroit.

Each of the four counties and the city of Grand Rapids was tabulated separately. To show our classification and extent of information obtained, table 1 gives the completed summary of Houghton County.

The whole survey is shown in table 2, in which only the incidence of goiter in relation to prophylaxis is shown.

Among the group not using iodized salt it will be noted that the incidence of goiter is less than half of

what it was in 1924. Much of this decrease is due to the use of iodized salt before 1930. Another important factor has been the frequent reports from the state department of health urging prophylaxis. Many were taking iodine in some form from their physician or buying the chocolate iodine tablets formerly used in Grand Rapids and other city schools. But in every county or city of both Michigan and Ohio in which the study has been made the percentage of goiter among those using iodized salt is only a fraction of what it is among those not using it. A valuable study was possible in the comparison of two cities, Houghton and Calumet, in Houghton County, only 30 miles apart. All natural factors determining goiter would be the same. Dr. Newitt and I examined all the children of the junior high and high school in Houghton on one day and the same age group of the junior high and high school at Calumet the next day. The results are given in tables 3 and 4.

The difference in these communities responsible for this marked increase in goiter in Calumet lies in the fact that Calumet is a mining town, and during 1932 the copper mines closed. Approximately two thirds of the families were on relief and only bag salt (non-iodized) was given to relief families. Further, families

who were buying their groceries were so constrained by finances that they too bought bag salt, which is cheaper than package salt. Therefore the use of iodized salt was discontinued in about two thirds of the homes in Calumet during 1933, 1934 and 1935. The increase in the number of goiters, and especially moderately enlarged, hyperplastic goiters, was most striking. In a period of three years, with the only source of food iodine closed to half of the homes, endemic goiter is proportionately as prevalent as it was before prevention was initiated.

To demonstrate what can be done by any county or locality in the control of endemic goiter I give here the results in Midland County, Mich., and call attention to the factors that count most in the success of this public health measure: First, this county supports an efficient county health department which has consistently urged the continued use of iodized salt. Also, their assistance in obtaining accurate information regarding the use of iodized salt during this survey makes the data from this county much more valuable.

TABLE 4.—Houghton County, Michigan—Calumet High School

	Total	Normal	Total Goiter	Per Cent Goiter
Using iodized salt.....	458	400	58	10.00
Not using iodized salt.....	350	199	151	43.14
Indefinite.....	43	29	14	32.55
	851	628	253	29.72

	Total	Normal	Total Goiter	Per Cent Goiter
Using iodized salt.....	3,089	3,031	58	1.9
Not using iodized salt.....	1,184	1,000	175	14.52
Indefinite.....	618	593	25	4.00
	4,891	4,633	258	5.23

TABLE 6.—Division of Health, Cleveland: Goiter Survey—January 1936

	Total	Normal No. 1	Small Goiter No. 2	Moderate Goiter No. 3	Cong. ad.	Hyperplastic Goiter	Per Cent Goiter
Using iodized salt.....	2,703	2,503	199	1	35	14	7.7
Not using iodized salt.....	2,529	1,752	757	20	48	208	30.7
Indefinite.....	761	624	136	1	15	22	18.00
	5,993	4,879	1,092	22	99	244	18.00

From this survey we find that: 45.1 per cent of children use iodized salt regularly, 42.2 per cent of children never used iodized salt, 12.7 per cent of children use iodized salt irregularly—only part-time or occasionally (classified as indefinite users).

Because of the scientific interest in this health measure the iodized salt has been frequently analyzed and recommendations have been made to the effect that only reliable grades of iodized salt be used. The incidence of goiter in this county was 32.7 per cent in 1924.

Approximately 63 per cent of the homes are now using only iodized salt. It is thought that previous to 1932 more than 90 per cent of the homes were using only iodized salt. In table 5 the group not using iodized salt shows only 14.5 per cent goiter compared to 32.7 per cent in 1924. This reduction undoubtedly

and feet. Because of the severity of these symptoms the patient was forced to stay in bed. Her arms and legs became paralyzed and she had periods of unconsciousness which often lasted for several days. April 8, 1936, she was admitted moribund to the surgical service of the Hillman Hospital, where a diagnosis of rectal stricture, intestinal obstruction and severe pellagra was made. On admission she was given immediate supportive and antipellagric therapy. The pellagrous lesions healed remarkably prior to her death on her eighth day in the hospital.

Postmortem examination revealed multiple large and small pulmonary infarctions in both lungs. Large, firm, pulmonary emboli occluded the main branches of the right and left pulmonary arteries, and the ovarian and hemorrhoidal vessels were thrombotic. The sigmoid and rectum were occluded for a distance of 6 inches by a chronic inflammatory process (?lymphogranuloma inguinale).

CASE 3.—J. S., a colored woman, aged 64, was in good health until early in 1933, when she had trouble with her "teeth and kidneys." Since that time she has had considerable difficulty in chewing. Early in January 1936 she noticed a loss of appetite, sore mouth and severe diarrhea, often having as many as twenty stools a day. A month later a dermatitis appeared over the dorsum of her hands and feet. March 2, 1936, she was admitted to the surgical division of the Hillman Hospital because of rectal stricture and hemorrhoids, which were of such

peutic substances. Uncomplicated cases of pellagra will rarely be fatal provided early, prompt, intensive and persistent treatment is given. The remaining three patients died, but each of them was admitted to the hospital because she had, in addition to pellagra, a disease requiring surgical treatment. In none of them can it be said that pellagra alone was the cause of death. Autopsies on each patient showed the presence of an organic disease in itself capable of causing death and, in each instance, healing pellagrous lesions.

In a previous study<sup>1a</sup> it was shown that the signs and symptoms, seasonal occurrence and predisposing dietary insufficiency are the same for the so-called alcoholic and the endemic types of pellagra. Present observations show that the patient with endemic pellagra is remitted of his disease by the rigid application of the same general principles of treatment as is the so-called alcoholic pellagrin.

#### SUMMARY AND CONCLUSIONS

1. Fifty cases of severe endemic pellagra were admitted to either the Hillman or the T. C. I. Hospital

\* One patient had edema and weight loss, if any, could not be accurately determined.

severity that, despite the patient's poor general condition, an operation was performed at once. Soon after the operation the patient was seen in consultation. She was emaciated and had extensive pellagrous stomatitis, glossitis and dermatitis. Antipellagric therapy was initiated at once and the pellagrous lesions rapidly disappeared. At the time of the patient's sudden death on her twenty-fourth day in the hospital she had no signs or symptoms of pellagra.

Postmortem examination showed an occluded rectal and sigmoid stricture (?lymphogranuloma inguinale), proctitis and arteriosclerosis. The pathologist found no evidence of pellagra.

#### COMMENT

It has been shown in the present study that forty-seven of fifty patients with severe endemic pellagra, admitted to the hospital for treatment, recovered when given a high caloric, high protein diet, large amounts of a potent, specific therapeutic agent, symptomatic and supportive treatment, rest, and good nursing care. It must be fully understood that the ingestion and assimilation of a proper diet and specific therapeutic agents and the rigid application of the general principles of treatment are much more important than the symptomatic treatment. The latter, however, often affords the patients comfort and, in certain instances, aids in remitting the disease. Exacerbation of any gastrointestinal symptoms must not deter the physician from continuing the administration of proper diets or thera-

and, as a result of the efficacy of treatment, only three deaths occurred. The previous death rate in the Hillman Hospital had been 32 per cent.<sup>3a</sup>

2. Postmortem examination of the three pellagrins who died showed the primary cause of death to be in case 1 a pulmonary embolus and a ball-valve thrombus of the right auricle and in case 2 bilateral pulmonary emboli, thrombophlebitis of the ovarian and hemorrhoidal veins, and stricture of the sigmoid and rectum. In case 3 the primary cause of death was not fully determined; this patient was operated on for an occluding lesion of the rectum and sigmoid, and an exact interpretation of this lesion and of the operation in terms of the cause of death was impossible. In each case the lesions of pellagra were either healed or showed definite signs of healing.

3. The signs and symptoms, the predisposing dietary insufficiency, the clinical course of the disease and the response to treatment of these patients with endemic pellagra were the same as those of pellagrins previously studied whose disease followed the chronic, excessive use of alcohol (so-called alcoholic pellagra).

4. These observations show that endemic pellagra, like so-called alcoholic pellagra, responds to the administration of a high caloric, high protein diet, large amounts of yeast, adequate rest and good nursing care.

bag salt since the depression. No case of hyperthyroidism was found among 47,360 children using iodized salt regularly.

In Cleveland among the group using iodized salt regularly 7.7 per cent had goiter and fourteen of these had large hyperplastic iodine deficiency goiters. Contrast this with Midland County, Mich., where the incidence of goiter was much higher than in Cleveland in 1924, but in 1935 among those using iodized salt regularly less than 2 per cent had goiter. The condition in Cleveland is due to two salt manufacturers in this district who could not make up their minds on the value of this method of goiter prevention and consequently put little or no iodine in their iodized salt.

The Cleveland Health Department in 1931 made an analysis of the various brands of iodized salt being sold in the community and found three different brands which contained no iodine, although each was labeled iodized salt (0.023 per cent of potassium iodide). The two companies responsible for this condition agreed to make their product conform to the label. On repeated analysis in 1936 of the various brands of iodized salt sold in Cleveland, we found several brands of iodized salt that contained only one-third the amount of iodine stated on the label and one brand sold by a large chain store which contains no iodine. The same two manufacturers in the Cleveland district are responsible. Again I want to state that all the nationally advertised brands contain iodine exactly as stated on the label. However, the average of thirteen brands for Cleveland was only 0.012 per cent, or half of what was stated on the package.

The laboratories of the Michigan State Department of Health found an average for thirteen brands sold in Michigan to be 0.018 per cent. All advertised 0.023 per cent potassium iodide or 0.02 per cent sodium iodide.

The Wisconsin State Department of Health analyzed thirteen brands sold in Wisconsin and found an average of 0.014 per cent, yet all were labeled 0.023 per cent or 0.02 per cent, depending on the use of potassium or sodium iodide.

In each study we found the iodine content of the nationally advertised brands and the trade brands prepared by these manufacturers for other companies to approach closely the amount advertised.

#### SUMMARY

It has been demonstrated that salt can be iodized accurately and that a high standard of efficiency can be maintained. It has proved the least expensive and most satisfactory of any method yet devised to supply deficient food iodine in endemic goiter districts.

This survey shows conclusively that the general use of iodized salt is an efficient and safe method of goiter prophylaxis. The study in Houghton County, Mich., shows that the discontinuance of iodized salt was followed by a marked increase in the incidence of goiter within three years.

Every state in which goiter is endemic is advised to meet the deficiency of food iodine by the general use of iodized salt. From our experience it is advisable to have the state health department laboratory analyze every brand of iodized salt every other year, at least, and insist on a high standard. An accurate stable product can and should be maintained. It is also very necessary that the department of health continue its advice on goiter prophylaxis at definite intervals. Otherwise, interest in this measure will die because of

the ease and simplicity of prevention. Attempts to interest and educate the public need not be aimed solely at the deformity of the neck. One should think of the number of cases of feeble-mindedness (cretinoid type), the many boys and girls who do not mature normally through puberty (clinical hypothyroidism), the many cases of cretinism and myxedema and the thousands of large tumorous goiters with an occasional cancer, each of which is only a sequela of endemic goiter.

For over twenty years Marine and I have consistently emphasized the importance of the replacement of the food element iodine. In meeting this deficiency we are preventing infinitely more than meets the eye, the goiter.

### THE PREOPERATIVE VISUALIZATION OF BREAST TUMORS

N. FREDERICK HICKEN, M.D.

R. RUSSELL BEST, M.D.

CHARLES F. MOON, M.D.

AND

T. TENNYSON HARRIS, M.D.

OMAHA

Tumors of the breast can be visualized *in situ* by contrast roentgenographic studies. The offending neoplasms are rendered visible by outlining them with such contrast mediums as stabilized thorium dioxide sol, lipiodine and air. This can be accomplished in one of two ways. The first method consists of injecting the milk ducts with the radiopaque substance and then making stereoscopic studies. The resulting roentgenograms, descriptively called mammograms, give an accurate anatomic pattern of the injected ductal system. Any pathologic condition that alters the size, shape or conformation of the lactiferous ducts is readily appreciated. Similar visualization studies can be made by inflating the breast tissues with air. This second form of study has been termed aeromammography. The technical simplicity and the diagnostic value of such visualizations are vividly portrayed in the cases reported here.

#### BILATERAL BREAST PAPILLOMAS

CASE 1.—Miss R. S., aged 41, complained of a bleeding breast. During the past three years she had intermittently observed two or three drops of a serosanguineous discharge escaping from the right nipple. Thinking that such secretions were always associated with the menopause, she dismissed the events as being unimportant. Two weeks before admission, however, she became alarmed, for a persistent hemorrhagic discharge seeped from the same nipple. Frequent examinations by herself and her physicians failed to locate the offending tumor. There had been no associated pain and she stated that there was no possibility of trauma being the exciting cause. The left breast seemed to be normal.

Both breasts were small and presented nulliparous characteristics. In the outer lower quadrant of the right breast was a small compressible tumor, which seemed to be confluent with the dilated milk ducts. Whenever pressure was applied to this cystic growth the regional ducts that led from the affected lobule became tense and distended, but no secretion could be expressed from the nipple. While the upper medial quadrant of the same breast was palpated, three drops of bright red blood were expressed from one gaping estuary. Painstaking palpation, transillumination and soft tissue roentgenograms did not demonstrate the offending tumor. The small cystic growth

tively. Most of the surgeons ignored the question and a few reported cosmetic results as being from fair to good. Under the heading of radical surgery it will be noted that 21 per cent of the cases of carbuncles treated by dermatologists were recorded as being treated radically. This does not give a true picture of the practice among dermatologists, however, as most of this group of cases occurred in the practice of one dermatologist who is associated with a large private group of physicians. The questionnaires specified that the heading "furuncle" was to include only those furuncles occurring about the face, head and neck; but some of the answers did not differentiate furuncles of the face from those occurring elsewhere.

The salient features of the answers to the questionnaires were that:

1. Dermatologists employ radical procedures much less frequently than surgeons.
2. Dermatologists employ x-rays much more frequently than surgeons.
3. The average duration of treatment by surgeons was nearly twice as long as under dermatologists.
4. The mortality was greater under surgical than under dermatologic treatment.

#### Summary of Replies to Questionnaire

#### TECHNIC EMPLOYED BY AUTHORS

1. Unfiltered x-rays, in a dose of from one-fourth to one-half skin unit to the affected area. This may be repeated in about three days if necessary. The theory underlying the use of x-rays in furuncles or carbuncles is that certain cells, probably lymphocytes or leukocytes, being very radiosensitive, are broken down and liberate powerful antitoxic substances, which more effectively combat the infection. The protective wall of fibroblasts is apparently unaffected. X-rays exert little or no actual bactericidal effect.

2. Specific immunization. This is accomplished by two means. At the first visit a culture is taken from which is prepared an autogenous vaccine, which is administered intravenously at intervals of two or three days, the interval being increased later to four or five days. Recent investigations have shown that a higher degree of immunization is obtained by the intravenous method of administration of vaccines as compared with the subcutaneous or the intradermal route and that this immunization is accompanied by a desensitization to bacterial proteins, whereas vaccine administered by the other routes is sometimes followed by an increased sensitiveness to bacterial proteins. The usual beginning dose is twenty-five million organisms in the case of the staphylococcus, and this is increased to fifty million,

one hundred million, two hundred million and so on. Severe systemic reactions are very infrequently encountered. The use of autogenous vaccine not only tends to shorten the course of the individual lesion but it is especially valuable in cases of recurrent furunculosis.

From the same culture obtained at the first visit one can prepare a suspension of bacteria for testing the lytic potency of a bacteriophage, and if the bacteriophage is active against the bacteria in question we have felt that the softening and resolution of the lesion was materially hastened by daily irrigation of the cavity of the lesion with bacteriophage and the use of a bacteriophage wet dressing for several hours following.

#### Formula of Alibour Water

	Gm. or Cc.
R Copper sulfate .....	1.6
Zinc sulfate .....	5.6
Saturated solution of camphor water.....	to 240.
Sig.: Dilute two tablespoonfuls to a glass of water and apply as a wet dressing.	

3. Local applications. In addition to the foregoing, we have employed with much satisfaction continuous wet dressings of Alibour water, the value of which is twofold. It is nonirritating except in extremely rare cases, and it is a very potent antiseptic and astringent, exerting a definite bactericidal effect on the open lesion as well as preventing reinfection of neighboring hair follicles from the purulent discharge.

We also employ hot flaxseed poultices for about one hour twice a day, alternating with the wet dressings, on the time-honored theory that the heat and possibly some active principle of the flaxseed exert a beneficial softening and sedative effect on the lesion. The poultice is made by mixing flaxseed meal and boiling water, placing within a single layer of linen or muslin and applying over the lesion after it has cooled enough to be comfortably hot. As soon as it becomes cold it is replaced by a hot one, and this is repeated for at least one hour twice a day.

4. Drainage. The lesions should be kept open and draining if pus is present. We do not favor incising early lesions. A single one-half skin unit dose of x-rays will frequently abort them. However, if pus shows at the surface or if there is obvious fluctuation, incision is indicated. Frequently a slight prick with the point of the scalpel will free the pus. Two reasons for keeping free drainage are (a) to prevent deep burrowing and extension with the formation of a carbuncle and (b) to allow more effective action of topical applications.

5. Phenol puncture. This procedure has been in vogue for many years and is particularly valuable for softening tough necrotic sloughs and "cores." A pointed tooth pick is dipped into 95 per cent phenol and with very light pressure is bored into the necrotic mass. The anesthetic effect of the phenol prevents any pain and the central portion of the lesion so treated soon liquefies and facilitates drainage and resolution of the lesion.

6. General care. The extreme pain of furuncles and carbuncles justifies the use of appropriate sedatives such as acetylsalicylic acid or codeine and some sleeping aid such as sodium amytal at night. Bromides should be avoided, since they are sometimes excreted through the sebaceous glands and may cause a folliculitis. In acute or extensive cases, especially with involvement of the face, rest in bed is imperative, fluids should be forced and simple nourishing food administered, although, if the lip is involved, vigorous chewing should be avoided.

Any physical abnormalities such as anemia, focal infection, diabetes or gastro-intestinal disorders should

expressed, the orifices of the milk ducts could not be located. The neoplastic mass transmitted light with the same facility as did the normal breast tissues; hence no differentiation was possible. Soft tissue roentgenograms likewise failed to locate or identify the tumor (fig. 5A).

In order to obtain some information concerning the nature of this new growth a No. 20 gage needle was plunged directly into the neoplastic mass. Considerable resistance was encountered, as if the needle was traversing a firm fibrous tumor, for neither cells nor fluid could be aspirated. Apparently this was a connective tissue tumor, the exact nature of which was not clearly understood. The transillumination test seemed to rule out a simple fibro-adenoma, for they are not translucent while this tumor was. The firm resistance imparted to the exploring needle seemed to preclude the possibility of this being a lipoma, for lipomas are not composed of connective tissue. All precision tests such as transillumination, palpation and soft tissue roentgenograms had failed to give sufficient information for the identification of this neoplasm.

It was felt that mammographic visualization might yield additional information concerning the nature of this puzzling tumor. Attempts, however, to introduce stabilized thorium dioxide sol into the milk ducts failed, for the small estuaries could not be located. Hence, the insufflation of air offered the only hope of visualizing the neoplasm.

Fig. 3 (case 1).—One segment of the normal left breast was injected with stabilized thorium dioxide sol. Observe the small ramifying ducts, the large cyst and the negative shadow in the center of the cyst, which was interpreted as being a papilloma.

capsule of the offending tumor, thus separating the neoplastic mass from its bed of compressed breast matrix (fig. 5B). Because it was a translucent encapsulated tumor, Dr. Harris made the roentgenologic diagnosis of a lipofibroma. A large encapsulated bilobular fatty tumor was removed from the breast. The enucleation was accomplished with ease, for the air had already separated the tumor from its glandular bed. The lipoma measured 3 inches (7.5 cm.) in thickness and was 4 inches (10 cm.) long. It was composed of fatty tissue held together by a loose connective tissue stroma. Apparently the fibrous matrix was responsible for the resistance encountered by the exploring needle.

The patient made an uneventful convalescence and the emphysema completely disappeared during the next six days.

In this particular case the single aeromammogram vividly portrayed the characteristics of this supposedly malignant tumor and identified it as a benign lipofibroma. Similar experiences have taught us that insuf-

flations of air are valuable in facilitating the diagnosis of breast tumors, particularly lipomas, fibro-adenomas, simple retention cysts and carcinomas. Aeromammograms, however, have definite limitations, for they do not visualize small papillomas, early carcinomas, small

Fig. 4 (case 1).—The cystic cavity and the proliferating papilloma, confirming the mammogram.

retention cysts or cystic dilatation of the milk ducts. In order to visualize such tumors, the lactiferous ducts must be injected with some contrast medium. The combination of the ductal injection and the insufflation of air is ideal, for it permits a complete visualization of all the structures of the breast.

Fig. 5 (case 2).—A, soft tissue roentgenogram of right breast, failing to outline or define the offending neoplasm. B, the breast was inflated with 765 cc. of air. The air separated the breast matrix from the skin, the pectoral muscles and the neoplastic mass. The air dissected along the capsule of the tumor, thus outlining the lipoma.

These two cases are typical of many others which we have studied by contrast mammograms. Detailed discussions of technic, interpretations, limitations and indications for mammography have been reported else-

The physicians who assisted me in this survey were Drs. M. B. Beckett, A. W. Newitt and F. C. Forsbeck from the state department of health and Dr. H. S. Towsley from the division of pediatrics, University of Michigan Medical School. All readily adapted themselves to the same classification and method of examination that was used in the previous examination in

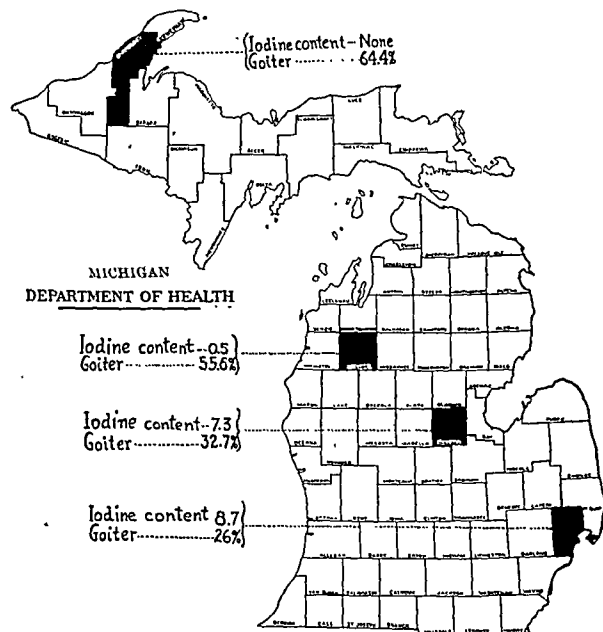

Chart 1.—Goiter survey of school population: Iodine in water estimated in parts per billion.

Michigan and was also the method used in the original survey in Akron. In every case we made a manual examination of the neck, palpating each lobe of the thyroid, estimating the size, and feeling the consistency and the presence or absence of nodules or persistent thyroglossal stalk.

The classification of goiter must begin with an appraisal of the normal thyroid. At the beginning of our study in Akron in 1916 Marine's standard of anatomically normal thyroid was one that does not exceed 0.5 Gm. of thyroid per kilogram of body weight. In an average size adult a strictly normal thyroid would average from 20 to 35 Gm. Correspondingly an adolescent child would have a thyroid weight of from 15 to 30 Gm. Further, Marine estimated that each lateral lobe is approximately the size of a medium sized lima bean, while the isthmus can barely be palpated. We stated in our first report<sup>2</sup> of this study (1917) that the lateral lobes, if normal, could not be palpated. By 1924 our knowledge and technic had improved to a point at which we taught the physicians who assisted with the survey in Michigan to palpate the lateral lobes in each case and to think in terms of consistency as well as of size. If distinct enlargement of one or both lateral lobes can be palpated, i. e., two or three times normal, and a change in consistency, soft or spongy, it is called a small goiter. If beyond a doubt this enlargement cannot be felt, the thyroid is called normal. The small goiter includes everything from a distinct enlargement to a visible goiter in which one or both lateral lobes cause a definite bulging of neck and the median lobe is easily apparent; i. e., from one-half to one inch (from 1.27 to 2.54 cm.) in thickness. In

such a goiter there may be as much as ten times the amount of a normal gland. If the enlargement is deforming, i. e., considerable bulging of one or both lateral lobes, it is called a moderate goiter. This moderate goiter included all average sized goiters. Only the exceptionally large deforming thyroid is called large goiter. Thus we had originally the following classifications: (1) normal, (2) small goiter, (3) moderate goiter and (4) large goiter. In all the surveys in Michigan we used only the numerals 1, 2, 3 and 4, but the meaning is exactly the same as the original classification.

The survey had three main objectives: (1) incidence of goiter in relation to the use of iodized salt, (2) the safety of the continued use of iodized salt and (3) the accuracy and dependability of this method of replacing food iodine. Therefore it was necessary to know in each case whether or not they were using iodized salt. To this end blank cards were sent to the school several days preceding the examination so that this information could be given with some assurance of accuracy. From our experience, however, these data can be procured with accuracy only when directed by public health nurses.

It was obvious from the start that our data would naturally fall into three groups: (1) those using iodized salt regularly for years, (2) those not using iodized salt at all and (3) all those in which the information is too indefinite to be classified with either group 1 or 2 and grouped under the heading indefinite. We frequently encountered such conditions as "Used iodized salt regularly from 1924 to 1930, but none since" or "We have used iodized salt regularly for the past three years, but none before that." In the reexamination of

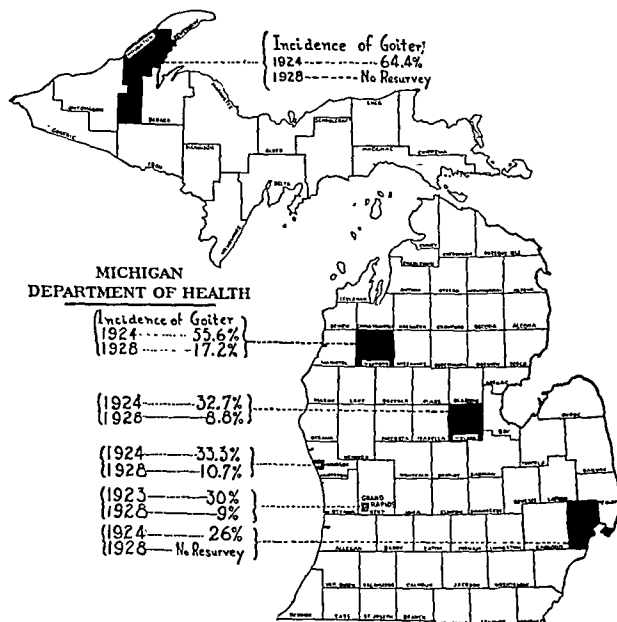

Chart 2.—Goiter survey in 1923 and 1924: School children examined, 65,537; incidence of goiter, 38.6 per cent. In 1928, school children examined, 50,134; incidence of goiter, 9.9 per cent.

1928 and in the yearly examination of school children in Detroit and Grand Rapids we found a most striking decrease in goiter during the first four years. Therefore, if a child stated that he had used iodized salt regularly for three years or more he was classed as using iodized salt, and if he had not used it for three years he was classed as not using iodized salt.

2. Marine, David, and Kimball, O. P.: The Prevention of Simple Goiter in Man, *J. Lab. & Clin. Med.* 3: 40-48 (Oct.) 1917.

fore, of an early malignant growth by roentgen examination must first take into consideration the point at which "early malignancy" is to be placed. If the presence of the first neoplastic cells beyond normal limits, a condition often ascertained with difficulty even with the aid of the microscope and in the hands of the most experienced pathologist, is to be regarded as the

Fig. 2.—A diagnosis of chronic cystic mastitis was made from the sections of the breast in figure 1 because the main tumor mass was excised and withheld from the pathologist so that another area of malignant involvement was difficult to find macroscopically. The patient subsequently died with widespread metastatic malignant lesions.

"critical" point for establishing the earliest diagnosis of malignancy, then the use of the roentgen rays is futile at this stage. But if one proceeds with open eyes, there are other grounds for enthusiastic consideration of the roentgen examination. Its continued application seems warranted, especially in the large clinics where there is much material and where close cooperation among clinician, surgeon, pathologist and roentgenologist can be arranged.

We have had the opportunity to obtain the opinion of an expert pathologist<sup>5</sup> who studied sections of amputated breasts from forty-one patients in our private practice and from the tumor clinic of the Skin and Cancer Hospital. This material is naturally too meager on which to base statistical conclusions but does furnish some revealing data. The fact that the percentage of correct preoperative roentgen interpretations was higher than that made by the pathologist when limited to his macroscopic studies, but lower than that made after his histologic examinations, is in itself very encouraging. This feeling is further enhanced by recalling cases in which the roentgen diagnosis was the single cause for revision of the pathologic report, the initial disagreement between the roentgenologist's and the pathologist's observations leading to further histologic study resulting in correction of the diagnosis.

#### REPORT OF CASES

**CASE 1.**—A patient, aged 70, was operated on Oct. 4, 1935, by Dr. J. F. McCloskey at the Skin and Cancer Hospital for a lump in the right breast, diagnosed as probably carcinoma. No palpable lymph nodes were present in the axilla. The pathologic report was chronic cystic mastitis, but the roentgen diagnosis was malignant neoplasia, with a moderate generalized

cystiphorous desquamative epithelial hyperplasia of the entire breast. On further inquiry it was learned that the amputated breast was first turned over to the research laboratory, where a part of the actual tumor was dissected out. Sections selected by the pathologist revealed only evidence of chronic cystic mastitis (figs. 1 and 2). In the roentgenograms a nodular neoplasm is visible in the right breast (the nipple of which was pulled forward at the time of the roentgen examination). Very little subcutaneous fat is present, but many fatty loculi are irregularly distributed throughout the body of the gland itself. While no cysts are present large enough to be definitely discernible, the moderately increased thickness and density of the stromal structures were the basis for the roentgen diagnosis of chronic mastitis, and, because of the patient's age, cystic degeneration was inferred. The visible lobulation and radiating extensions of the tumor margins led to the diagnosis of malignancy. While a check of the histologic appearances of the sections gave no reason to change the pathologic report, malignant metastasis developed and the patient died seven months after the operation.

On reviewing the material of this report we learned of the partial dissection of the tumor by the research pathologist, and in his sections there was unequivocal evidence of malignancy.

While experienced pathologists are content to give opinions on pathologic changes in the breast from microscopic examination of small sections of areas selected macroscopically, they realize that frequently systematic examination of sections of the whole breast are necessary to gain a true impression of the state of the whole gland. One small section may show malignancy while another may reveal cystiphorous desquamative epithelial hyperplasia and still another some other pathologic change.

It is conceded that carcinoma may be present in areas not suspected from macroscopic examination. One of the possible advantages of the roentgen examination is expressly in this connection. The equivalent of macroscopic examination of the whole gland is made available and the pathologist is given more aid in selecting suspicious areas for histologic study.

Excepting for one case in this series, the patient or the clinician or both found a tumor in the breast prior to the roentgen studies.

Any tumor that is palpable can be demonstrated in the roentgenogram. If tumors too small

for detection by palpation could be revealed, the roentgen examination might become more essential in breast tumor diagnosis. As a matter of fact, this can already be partially realized if resort is made to serial roentgenographic studies of the normal breast in women

Fig. 3.—The delicate radiating striations springing from the periphery of this deep seated neoplasm was thought to indicate malignancy.

5. The histologic studies were made by Dr. Damaso deRivas, Professor of Parasitology, University of Pennsylvania School of Medicine, and Dr. Eugene Case, pathologist to the Graduate Hospital of the Graduate School of Medicine, University of Pennsylvania.

is due to the continued use of iodized salt from 1924 to 1932. In the original survey one third of the children of this county showed a well developed goiter, and a questionable enlargement was seen in almost every child. We now find an anatomically normal thyroid in 90 per cent; i. e., the theoretically normal thyroid that twenty years ago Marine said could be found only along the sea coast. Also in these schools we examined children of five families, all of whom stated that they had

Chart 3.—Incidence of goiter in Michigan from 1924 to 1936.

purposely avoided iodized salt for years (from three to six) on the advice of their physician. On questioning we found that all five families had been advised by a dermatologist of Saginaw, who gave the advice on the theory that iodized salt caused acne vulgaris. Among these children there were eight cases of moderately enlarged, soft, spongy hyperplastic goiters, demonstrating as nothing else could the value of iodized salt in the prevention of goiter.

Not one case of acne was found among the children of these five families, nor did we find more cases of acne than would be expected among the 3,000 children using iodized salt regularly for years. But the important fact is that of these 3,000 children less than 2 per cent had goiter.

In January 1936 a goiter survey was made in Cleveland. This survey was made by the school health service of the city health department through the parochial schools. Here again there were two objectives: (1) the incidence of goiter and (2) the use of iodized salt. To make our data as accurate as possible, the school health nurse went into each schoolroom several days in advance of the examination, explaining the importance of this study, and arranged for each child to take home a blank card bearing his name and the questions on the use of iodized salt. This blank was to be filled out by the parent. The information was then transferred to his goiter card, on which our examination was recorded. The examinations were made by Drs. Sloan, Jackson, Larsen, Hutchison and Kimball. The examination and classification was the same as is described for the Michigan survey. The fifteen school districts were selected by the school health service as representative of average conditions in Cleveland. Table 6 gives the result of this survey.

A similar study made by me for the city health department through the parochial schools of Cleveland in 1924 showed 30 per cent goiter among school children (all grades, boys and girls). Today, as shown by data in table 6, among those not using iodized salt the incidence of goiter is still 30.7 per cent. This is the answer to any one who thinks that the incidence of

endemic goiter goes in waves; i. e., in 1924 we were at the peak of the wave due to natural causes and by 1935 we were at the low ebb of natural causes. Our results show that we are still at the 1924 peak for those not using any prophylactic iodine.

The actual changes that have taken place in Michigan and Ohio since 1924 can best be shown graphically. The incidence of goiter throughout Michigan was 38.6 per cent in 1924 and 9.9 per cent in 1928 and 8.2 per cent in 1935.

The true condition of Cleveland is strikingly shown in figure 4. The group not using iodized salt shows no change, while the group using iodized salt shows a decrease from 31 per cent to 7.7 per cent. In each county or city in Michigan the group listed as not using iodized salt showed some reduction in goiter over the 1924 survey. In some instances it is less than half. We can attribute this to the fact that a very high percentage of the homes used only iodized salt from 1924 to 1930, but many have used only bag salt (noniodized) since the depression. They were listed with those not using iodized salt because we had arbitrarily set three years as the limit for using or not using, but its use for the preceding years had a very definite effect. We cannot accurately evaluate this effect, so we stress only the percentage of goiter at present, which shows the entire reduction.

In Cleveland we had an entirely different situation. There was a great difference of opinion in the medical profession and consequently a distinct division of thought and advice was given the public. Our survey this year showed that 87.3 per cent of the homes had definitely decided either for or against iodized salt. The group of nonusers had purposely avoided it since it came on the market in 1925, for it was then that they were so strongly advised against its dangers. Also that was the time when the state and city departments of health urged the general use of iodized salt throughout this endemic goiter district. This definite stand for or against the use of iodized salt has accidentally pro-

Chart 4.—Incidence of goiter in Cleveland from 1924 to 1936.

vided here in Cleveland indisputable data that should establish definitely the value and future of this method of prevention.

In Cleveland we did not find any case of clinical hyperthyroidism among the 6,000 children examined. In Michigan, among 9,429 children not using iodized salt, we found four with moderately sized nodular hyperplastic goiters with very definite clinical signs of toxicity. Three of these stated that they had never used iodized salt and the fourth stated he had used only

accentuation of the stromal striations leading up to it from the breast itself. A diagnosis was tentatively made of a benign, probably inflammatory, process and within four weeks an approximate total of 1,600 roentgens was delivered into the region of this node by cross-fire roentgen irradiation. At the end of this time the node had completely disappeared; both palpation and roentgen examination did not disclose any evidence of its presence.

The case has been followed for fifteen months and so far no changes have occurred (fig. 5).

The least number of errors in the roentgen diagnosis of malignant mammary tumors was made in the atrophic breasts, most of which occur in the fifth and sixth decades, usually at or after the menopause. In these breasts the single examination has already exhibited its diagnostic possibilities for accuracy. The chief reason for this is the clear visibility of the tumor margins afforded by the homogeneous fat content of the breast, the fat being a good radiolucent contrast medium. It is often surprising how easily discernible are the striations of malignant infiltrations radiating from the margins of a growth in breasts of this type; this is also partially true when there is excessive fat infiltration in the active breast of the younger individual. This is a particularly fortunate circumstance because it is in this type of breast that the clinician and the surgeon have the greatest difficulty in making a diagnosis.

Some slow growing tumors show a tendency to remain localized, enlarging slowly by gradual peripheral accretion of new cells, which press the tumor bed centrifugally so that compactness develops in a narrow zone adjacent to the neoplasm, thus creating a smooth surface, and leading to an erroneous roentgen impression of benignancy. When such tumors are small and confined within the limits of the body of the gland itself, it is hard to understand how the roentgen examinations can be of real help in deciding the question of malignancy. But it is characteristic of this kind of tumor sooner or later to enlarge "out of bounds" and to cross the sharp limiting zones of the mammary gland, either forward into

Fig. 7.—The nodule visible in this breast felt smooth and freely movable and therefore seemed benign but was thought malignant from its roentgen appearance because of the invading posterior margins.

the clear fatty subcutaneous layer or backward into the clear cleft between the corpus mammae and the pectoral muscle. Under such conditions it is justifiable to raise the question of malignancy. This was rather graphically impressed on us after reviewing whole breast sections of an instructive collection, an opportunity kindly given us by Dr. Joseph McFarland in his laboratory in the University of Pennsylvania School of Medicine.

#### NODULARITY

Palpation of the breast is probably one of the least satisfactory procedures in physical diagnosis. Not only does there seem to be a lack of standardization in the technic, but there is also chaotic misinterpretation of the results. The consistency of a breast is frequently referred to without the slightest appreciation of how a thick subcutaneous layer of fat may modify this prop-

Fig. 8.—Section of nodule in figure 7, showing its malignant histologic characteristics.

erty. The multinodularity often ascribed to a breast is not commonly due to the unevenness of the surface of the gland itself but to isolated lobules of fat separated from one another by dense subcutaneous projections of the suspensory ligaments of Cooper. This can be proved by subcutaneous severance of the attachments of these ligaments, which abolishes the palpable multinodularity. The distribution of the subcutaneous fat, the extensions of the fibrous suspensory ligaments through it to the skin and the character of fat infiltration in the body of the gland itself are shown with extreme clarity in the roentgenograms. This should engender a reliable approach to the interpretation of the observations made by palpation and obviate undercutting of the skin for clinching the diagnosis. In the roentgenogram shown in figure 6, extensions of the mammary parenchyma into the bases of many of the subcutaneous projections of the ligamenta suspensoria are seen, dividing the subcutaneous fat into lobules, making differential diagnosis from nodules in the gland itself difficult by palpation alone.

Deep seated nodules are found more easily by the roentgen examination than by palpation. This implies, of course, that the proper roentgen technic has been employed for demonstrating the tissues in the base of the gland. Superficial nodularity is so clearly shown in the roentgenograms that there is no difficulty in making a differential diagnosis between false nodularity

in the lower portion of the breast did, however, transmit light, but no other abnormalities were noted. The left breast was apparently normal.

It was appreciated that the right breast harbored a bleeding neoplasm and attempts were made to locate the tumor by means of contrast mammographic studies. The dilated milk duct, from which the hemorrhagic fluid escaped, was cannulized with a blunt No. 25 gage needle and was injected with 1 cc. of stabilized thorium dioxide sol. The resulting roentgenogram clearly outlined the course of the milk duct and demonstrated a definite filling defect, which protruded into and completely filled the ductal lumen (fig. 1A). Apparently this filling defect was caused by a proliferating tumor arising from the walls of the milk duct. To exclude the possibility of this negative shadow being an artefact, such as an air bubble, a second mammogram was taken after an additional 3 cc. of stabilized thorium dioxide sol had been introduced into the same duct. The contrast fluid passed beyond the obstructing tumor and filled the terminal lacteals and acini. Not only was the first tumor still visible but a second and similar neoplastic mass was observed at the bifurcation of one of the smaller communicating ducts (fig. 1B). Thus two papillomas were definitely localized by these visualization studies.

In an attempt to understand these roentgenologic changes better and in order to have a normal breast pattern for comparison, four lactiferous ducts of the left nipple were cannulized and injected with stabilized thorium dioxide sol. The stereoscopic mammograms presented a startling and completely unexpected condition. The injected segment of the breast matrix was found to contain a large cyst, which was formed by the confluence of several adjacent ducts. The delimiting wall of the cyst was clearly seen, but its central portion was not distended with the thorium dioxide sol, as there seemed to be a moderate sized filling defect present (fig. 3). Repeated mammograms indicated that this negative shadow maintained a constant size, shape and position; therefore it was interpreted as being a pedunculated papilloma arising from the cyst wall.

Appreciation of the tendency of papillomatous neoplasms to undergo malignant transformation, combined with the fact

left breast several dilated ducts had fused so as to form a cyst, and arising from its wall was a friable, nonbleeding pedunculated papilloma (fig. 4).

This particular case presents several interesting features. First, it emphasizes the fact that papillomatous tumors are often multiple and that they may arise in any segment of the lactiferous ducts. Second, it clearly

Fig. 2 (case 1).—Excised breast, showing dilated duct containing two papillomas

demonstrates that a simple excision of one tumor is not curative, for similar growths may be developing in other portions of the same breast. Third, it proves that papillomas may simultaneously involve the two breasts and that the absence of symptoms and physical signs is no assurance that such tumors are not present. Fourth, the multiplicity of these neoplasms lends credence to the belief that they may have a certain constitutional or endocrinologic background. Fifth, it most emphatically demonstrates the clinical value of mammographic studies in the diagnosis of breast neoplasms. The mammograms not only locate the offending tumors but also determine the degree of involvement. Such information is valuable, as it assists the surgeon in selecting the proper therapeutic procedure.

#### LIPOMA OF THE BREAST

CASE 2.—Mrs. M. F., aged 21, a housewife, was worried about a lump in her breast. Two months before admission while bathing, she accidentally discovered a small asymptomatic tumor in the right breast. About this time she became pregnant and both breasts began to enlarge. The neoplasm, however, grew very rapidly, for during the past two weeks it had more than doubled its original size and now interfered with the free motion of her arm. She had never observed a discharge from the nipple nor had the breast been subjected to trauma. Her physician interpreted this history and his observations as signifying a rapidly growing carcinoma which was being activated by an early pregnancy.

The right breast was twice as large as the left and in the upper half there was a large bulging tumor mass. It was firm, slightly tender and partially fixed, for it blended insensibly into the adjacent breast matrix. The overlying skin was tense and apparently attached to the tumor, but one could not determine whether the fixation was caused by an actual cellular infiltration or by contact pressure with the neoplasm. The tumor mass was not adherent to the pectoral muscles, for a layer of normal breast tissue seemed to separate the two. The nipple was partially inverted and, as no secretion could be

Fig. 1 (case 1).—A, the bleeding duct was injected with 1 cc. of stabilized thorium dioxide sol. The mammogram evidenced a filling defect, which was interpreted as a papilloma protruding into the ductal lumen. B, the same duct was injected with an additional 3 cc. of stabilized thorium dioxide sol. The entire duct and its tributaries were visualized and two filling defects were seen, indicating multiple papillomas.

that these tumors were bilateral, caused Dr. Moon to remove both breasts. Examination of the excised specimens verified the mammographic studies. The right breast contained a large dilated duct which harbored two bleeding papillomas (fig. 2). The tumors were too small to be detected by palpation or to cast a dark shadow on transillumination. In the asymptomatic

DERMATITIS FROM DYED AND OTHER-  
WISE TREATED CITRUS FRUITS

## REPORT OF TWO CASES

EUGENE F. TRAUB, M.D.  
 RICHARD E. GORDON, M.D.  
 AND  
 LAIRD S. VAN DYKE, M.D.  
 NEW YORK

The practice of coloring citrus fruits by means of dyestuffs, aniline and other substances to give a fully ripened appearance has come into vogue only during the past two to two and one-half years. A large number of chemicals have also been used in recent years to ripen artificially and preserve the fruit for distant markets. These include ethylene gas, kerosene, paraffin, soap, wax and borax. The fruit is also washed in various fungicidal solutions, the formulas of which are generally secret and known only to the manufacturers. Some orange growers use insecticide sprays on their trees, while others cover each tree with a sort of tent into which is pumped hydrocyanic gas. It has also been found that gases from the exhaust pipe of an automobile have a ripening effect on green fruit skins, an action similar to that obtained with ethylene, and as a result this method also has been employed. The United States Department of Agriculture informs us that there is some evidence that oranges may themselves produce small amounts of ethylene during the natural fading out of the green color in the peel after picking, and it is known that this is the case with other fruits. It is asserted that 90 per cent of the Florida oranges in the New York markets are artificially colored. According to the United States Department of Agriculture the permitted food dye used for artificially coloring fruit is Yellow O B, as well as a combination of two dyes similar to sudan I and sudan II except that

occurring from wrist-watch straps dyed with amidoazotulene hydrochloride, which contains one of the same radicals found in Yellow O B. Three different brands of Florida oranges purchased in the market where the patient worked were used for patch testing. All three brands were labeled "color added." In addition we secured some Florida oranges that were picked from the trees and delivered directly to us, no treatment or color having been added.

The California oranges furnished us for the sensitivity test were accompanied with the following information from the United States Department of Agriculture:

The unwashed oranges were of the Washington navel variety and had not been treated in any way. The washed oranges had

Fig. 2.—Upper area represents a negative patch test to the inside of a dyed orange peel. Lower area is a positive patch test to the outside of a dyed and treated orange peel.

Fig. 1.—Dermatitis of face in case 1 (hands and forearms similarly affected).

one is formed by coupling xylydine and amidoazoxylene on beta-naphthol, and the other by coupling orthotoluidine on beta-naphthol, both processes being carried out in alkaline solution. Yellow O B is known to chemists as orthotoluene-azo-beta-naphthylamine. In a recent article Louis Schwartz<sup>1</sup> draws attention to a dermatitis

From the Skin and Cancer Unit of the Post-Graduate Hospital.  
 Mr. Louis Schwartz collaborated in the testing of the normal subjects with orange peels and dyes.  
 1. Schwartz, Louis: Skin Hazards in American Industry, Pub. Health Bull. 229, part 11

been given the commercial treatment being practiced generally at the season at which these oranges were picked. They were not treated with ethylene, although similar oranges earlier in the season would be treated with ethylene.

The oranges from the grove were first dumped into a long metal tank containing a solution of 2 parts of boric acid and 1 part of borax, so that the total content of borates was about 6.9 per cent. The oranges were kept in this solution for two and one-half minutes, the solution being at a temperature of 117 F. From this solution they went to another tank, where they were washed with soap and water. The soap used was a liquid soap labeled "Bobrick's Citr-O-Zone No. 1 for Oranges Bobrick Mfg. Co., Los Angeles." The oranges were then passed under sprays of clear, clean water and then went through a drier.

Both the washed and the unwashed oranges came from a grove at Upland, Calif. The trees are about 30 years old. The trees had not been sprayed or dusted this season. They will be either sulfured or fumigated with cyanide after the fruit is picked.

There has been no special law passed with reference to using dyes on oranges. The federal Food and Drugs Act provides that a product shall be considered adulterated if it is stained or colored in a manner whereby damage or inferiority is concealed.

Some years ago a standard for the maturity of oranges was adopted which provided that an orange would be considered mature if the ratio of soluble solids to acid calculated as anhydrous citric in the juice was 8 to 1 or greater. When coloring was first practiced on oranges it was held that oranges were mature when judged by this ratio and that inferiority was not concealed by coloring them. Last fall, however, the department issued a notice that after Sept. 1, 1936, they would consider that oranges were colored to conceal inferiority regardless of

where.<sup>1</sup> A personal experience (N. F. H.) with more than 320 contrast mammograms testifies that they are invaluable in the diagnosis and recognition of mammary neoplasms.

#### CONCLUSIONS

1. Tumors of the breast can be visualized by contrast roentgenograms made by introducing radiopaque substances into the milk ducts or by inflating the breast tissues with air.
2. Tumors arising within or communicating with the milk ducts are best visualized by introducing stabilized thorium dioxide sol into the diseased ducts. The stereoscopic mammograms locate the tumor and portray its identifying characteristics.
3. Tumors arising in the periductal tissue or those having no communication with the milk ducts can be visualized by inflating the breast with air. A large encapsulated lipoma was visualized by this method.
4. A combination of the ductal injection and the insufflation of air produces the most satisfactory visualization patterns of the structures of the breast.
5. Lipoma, fibro-adenoma, simple retention cysts, cystic degeneration of the ducts and carcinoma are some of the tumors that have been visualized preoperatively and correctly diagnosed.

### AN EVALUATION OF THE ROENTGEN DIAGNOSIS OF EARLY CARCINOMA OF THE BREAST

JACOB GERSHON-COHEN, M.D., D.Sc. (Med.)

AND

A. E. COLCHER, M.D.

PHILADELPHIA

An accurate roentgen diagnosis of any breast lesion based on recognition of morbid anatomic change presumes familiarity with the normal anatomic roentgen appearances. In a recent report of the normal breast we<sup>1</sup> indicated some limitations of the roentgen examination in such borderline pathologic states as mazoplasia, cystiphorous desquamative epithelial hyperplasia, epitheliosis and adenosis. Since the roentgenologist can attain little more accuracy than the pathologist, if limited to a macroscopic examination in making conclusive diagnoses of breast lesions, claims made for the roentgen studies inferring accuracy akin to the pathologist's microscopic studies must be carefully analyzed. This is well exemplified in those cases of fibro-adenomas of the puberal period when clinically, roentgenographically and macroscopically a diagnosis of neoplasia is agreed on only to be controverted by the microscopic finding of simple hyperplasia.<sup>2</sup> While it is difficult to credit some of the recent enthusiastic reports on the roentgen examination of the breast which seem almost tantamount to histologic studies, the high percentage of roentgen interpretations that were confirmed by microscopic examination of the tissue<sup>3</sup> is remarkable.

#### ROENTGEN CRITERIA FOR MALIGNANT CONDITIONS OF THE BREAST

When we speak of any method for the detection of early neoplastic changes, it might be well to make clear first when neoplastic changes are early. The pathologist regards malignancy as early when he discovers microscopic invasion of any proliferating group of cells or tissue beyond normal bounds. But it is very likely that cells are malignant before this invasion occurs, and some pathologists endeavor to diagnose malignancy on the morphologic changes they observe in the cell itself while still within its normal confines. Certainly with the present limitations of knowledge of the diagnostic applications of the roentgen rays a diagnosis of malignancy at this early stage seems ludicrously hopeless. However, if malignancy were regarded in most instances as simply a later stage in the evolution of neoplasia, the beginning of which is always benign, like tumors of the type classified as adenoma, fibro-adenoma and papilloma, the prob-

Fig. 1.—The neoplasm in this breast was regarded as malignant because of the spreading irregular margins.

lem would be relatively simple. There are some good reasons to look on this idea as tenable. The occurrence of malignancy in about 20 per cent of cases of Schimmelbusch's disease is an example in point. This disease begins with what Cheatle<sup>4</sup> regards as a desquamative epithelial hyperplasia with cyst formation, usually occurring in the late twenties and early thirties. In the next stage, usually in the late thirties and the forties, a radical neoplastic change takes place in the biology of epithelial growth, although the cells remain within normal but distended boundaries. Papillomas are conspicuously present at this stage, and the earliest neoplastic changes that can be recognized by the pathologist occur at this time. Cheatle has seen all three stages of transition in breasts at this period, and he logically remarks on the similarity of these changes with the development of tar carcinoma in mice. The dermatologist and gynecologist are also acquainted with the transition of benign leukoplakia, warts and papillomas into malignant processes. The diagnosis, there-

4. Cheatle, G. L., and Cutler, Max: Tumors of the Breast, Philadelphia, J. B. Lippincott Company, 1931.

CASE 2.—S. L., a man, aged 35, Norwegian, a cook, stated that he did not have any skin condition until somewhat over two years before, when an eruption appeared on the hands. This was erythematovesicular and was most pronounced about the palms and fingers. The rest of the body was entirely free and clear. The patient stated that he had noticed that the handling of certain foodstuffs in his work as a cook seemed to aggravate the condition. He was quite definite in his history that oranges and to a less degree lemons and grapefruit seemed to cause flareups but only during the past two to two and one-half years, as he had always previously handled these fruits without irritation. Examinations for tinea on the hands and feet were negative both culturally and by a direct smear. All trichophyton, dermatomycol and oidiomycin tests were negative. The Wassermann and Kahn tests were negative. Patch tests were done by applying various foodstuffs with the following results: spinach negative, apple rind negative, strawberry rind doubtful, grapefruit rind +, orange rind +++, tomato rind negative, lemon rind ++, apple meat negative, strawberry meat negative, grapefruit meat negative, orange meat negative, tomato meat negative and lemon meat negative. All routine scratch tests, including thirty-two foods, all pollens and epidermals were negative.

It is interesting in this particular case to note that the patient's history is very definite as to the onset of his dermatitis, and that this onset coincides exactly with the time the practice of dyeing citrus fruits was first begun.

#### COMMENT

Both of our patients, but particularly patient 1, were studied for a long time before this report was prepared. Patient 1 has been under treatment for years and has repeatedly been hospitalized for observation and testing. Patient 1 had several attacks of dermatitis, one of which was attributed to arsenic, before the present trouble began. For this reason we have made every effort to exclude all other factors as far as possible by careful history, observation and patch tests. In addition to the tests performed on these two patients, a number of normal individuals were checked and the results are of considerable interest and significance. It was discovered that the manner in which the orange peel was applied to the skin had considerable bearing on the result obtained. In all the tests tabulated in the foregoing, the outer surface of the peel was simply laid next to the skin surface. We found, however, that if the peel was crushed or squeezed and some of the oils contained in it were expressed on the skin area to which the peel was then applied, many positive tests resulted, indicating that the concentrated oils so expressed, whether obtained from dyed or undyed oranges, were apparently a primary irritant. Eight physicians and nurses were tested with the rind of a California Sun-kist and a Florida color added orange. The test material remained on all for from twenty-four to thirty-six hours except that in the case of the senior author (E. F. T.) the reaction was so severe in thirty minutes (erythema and vesiculation) that the patches had to be removed. None of the seven others showed a reaction to the skin of the Sun-kist orange, but three reacted positively to the dyed Florida orange. In two the reaction was strong enough to cause vesiculation and small bleb formation. Four of the same group applied the pure powdered dyes in a refined white liquid petrolatum. Three showed no reaction after twenty-four hours, but one was positive to all the dyes (Yellow O B, sudan I and sudan II) after seventy-two hours—the control with the white liquid petrolatum was negative. Although the senior author failed to react to the dyes in oil after twenty-four hours, there was marked erythema and vesiculation present at the site of the F. M. C. No. 1 and to a less degree at the place of the

Yellow O B test in the soap solution supplied to us from a Florida packing house. The soap solution control was negative.

These additional tests have demonstrated that the manner of application of the orange peel is of considerable importance, because crushing or squeezing the rind must be avoided if the patch test is used to determine sensitivity to substances applied to the outside of the peel. Delayed reactions should be watched for, as these occur occasionally. The following facts seem important (case 1):

1. A visit to the fruit market would immediately be followed by a flareup in the patient's skin eruption even though nothing was actually handled.

2. When the patient was given a dyed orange to handle for a few minutes while in the hospital, erythema and vesiculation could gradually be seen developing.

3. Keeping the patient away from citrus fruits always promptly freed him from his eruption, which invariably returned within twenty-four to forty-eight hours after he returned to the market.

4. Patch tests with dyed fruit produced not only local but focal and general reactions as well.

5. Patch tests with known untreated and undyed fruit skins gave negative results.

6. A circumstance of case 1 for which we are unable to account on the basis of information supplied us and despite our many repeated tests is the positive reaction to undyed oranges from California. All known dyed fruit from Florida gave positive tests, while the fruit from this state, which to our certain knowledge was undyed, gave repeatedly negative tests. The fact that this patient regularly reacted negatively to orange skins that we knew were untreated and undyed and gave positive tests to the citrus fruits from California obtained on the market here certainly seems to incriminate some preparation used on the California oranges.

#### CONCLUSIONS

1. For more than the past two years some citrus fruits have been treated with various dyes in addition to the other chemicals used for aging, ripening and preserving against molds and decay.

2. Two patients were seen with a dermatitis from handling such treated and dyed fruit.

3. In both instances the dermatitis was caused by the chemically treated or dyed fruit, our patch tests in both patients indicating Yellow O B dye as the prime offender.

4. Evidently the dye and chemicals used did not penetrate even to the inside of the peel, as patch tests with the inner surface of the rind gave negative results. Patch tests with the meat of the fruit also were negative.

5. Patch tests with dyed orange skin were repeatedly found to be positive in our cases. Patch tests with known undyed and untreated skins (Florida oranges) were negative.

6. In case 1, patch tests with dyed orange peel produced actual blistering of the skin and a severe focal and general reaction.

7. The dyes used on citrus fruits may definitely irritate some skins.

8. These dyes are not general irritants, because the majority of individuals do not react to them.

9. Hypersensitivity to the dyes may be acquired by constant and repeated exposure.

140 East Fifty-Fourth Street.

past the age of 25. This procedure is so simple and economically practicable that it is certainly worthy of serious consideration as a measure to be taken now in the control of mammary carcinoma.

CASE 2.—A woman, aged 50, was one examined in a series selected for roentgen studies of normal breasts. While she was being placed in position for the first examination, a small nodule was felt deep in the right breast, and from its roentgenographic appearance a diagnosis of a malignant neoplasm was made, based on the delicate radiating striations springing from its margins. After amputation this diagnosis was confirmed by Dr. Damaso deRivas from histologic studies (figs. 3 and 4).

Like Espaillet,<sup>6</sup> we made our most frequent errors in the diagnosis of mammary malignant growths in breasts if examined at the time of their greatest physiologic activity. The complexity of the stromal structures, the wide irregular intermeshing of the perilobular fatty infiltration and the extensive crossing of these shadows by those of the vascular tree, the superficial radicles of which are always so plainly visible in the roentgenograms, make visibility of the exact marginal limits of a

Fig. 4.—Section of tumor seen in figure 3, regarded as carcinomatous by the pathologist.

neoplasm very difficult. And since one of the essential criteria for malignant infiltration is the presence of an invading peripheral margin, the difficulties we encountered in differentiating the tumor margins from the complex normal adjacent and superprojected tumor bed tissue outlines can be readily appreciated. Our diagnostic judgment was correct on misinterpreted premises in two cases in which there was visualization of irregular margins of benign growths, due not to malignant peripheral invasion but to the reactive proliferation in the perifocal parenchyma, giving the growth a malignant appearance. It is mainly from this chance observation that we believe some element of speculation will generally be present in a diagnosis based on a single roentgen study of an adult breast, still active in a woman during the premenopausal years. What can be accomplished by serial examinations may be entirely another matter, and this has already been appreciated by Reiman and Seabold,<sup>7</sup> who made serial planimetric

measurements of breast lesions whose size and shape changed with menstruation and time. Warren<sup>8</sup> and Lockwood<sup>9</sup> also stressed the usefulness of this procedure, which deserves more emphasis.

Some have suggested that enlarged lymph nodes in the axilla, which can be demonstrated in the roentgeno-

Fig. 5.—In A an enlarged node is seen in the axilla, which disappeared after roentgen irradiation (B).

grams, have malignant or inflammatory identifying characteristics. Seabold<sup>9</sup> coped with this problem and at one time thought that there was a difference in density between inflammatory and malignant lymph nodes. We have failed to note such a difference, and to complicate the picture further is the frequent occurrence of enlarged nodes when the breasts are apparently normal. Radiation therapy appears to us as one method offering some diagnostic aid, and we have resorted successfully to this method.

CASE 3.—A woman, aged 42, married, menstruating normally, noticed a lump behind the right anterior axillary fold while bathing. There was some slight pain in the right breast but she was not sure that this was abnormal because she regularly experienced pain and discomfort in the breasts, usually preceding the onset of menstruation. The first roentgen examination nicely demonstrated this palpable node and revealed some

Fig. 6.—Invasion of mammary parenchyma into the bases of the subcutaneous projections of the suspensory ligament is seen, dividing the subcutaneous fat into lobules, making differential diagnosis from nodules in the gland itself difficult by palpation alone.

ous paper<sup>1</sup> suggest that contamination of food by persons infected with *Endamoeba histolytica* rarely happens under ordinary conditions of foodhandling.

#### SUMMARY

A protozoological survey was made of 1,072 food handlers in public dining rooms and kitchens in San Francisco. Twenty-two persons, or 2.04 per cent, were found to be infected with *Endamoeba histolytica*. The concomitant protozoan infections were found to be correspondingly low, as shown in table 1.

The clinical histories of the cases positive for *Endamoeba histolytica* are given in table 2.

## Clinical Notes, Suggestions and New Instruments

### HODGKIN'S DISEASE WITH LEUKOPENIA

SAM BOYER JR., M.D., DULUTH, MINN.

The blood picture in Hodgkin's disease has been of great interest and a subject for controversy since Bunting<sup>1</sup> published his classic work on this subject over two decades ago. Bunting postulated two constant features in the blood count: "an increase in blood platelets and an absolute increase in transitional cells." Furthermore, he stated that "in early cases there is a transitory increase in lymphocytes and basophils with a deficiency in eosinophils and a normal or low neutrophil percentage which is followed by a gradual decrease in lymphocytes and an increase in eosinophils. In late cases there existed a marked neutrophilic leukocytosis with a diminution in white cell elements other than in those cells and the transitionals." In the early cases of one year or less in duration he found that there was a normal or slightly diminished total white blood cell count and in those of longer duration a moderate or sometimes extreme leukocytosis.

Numerous contributors have disagreed with Dr. Bunting. Barron,<sup>2</sup> Cooper,<sup>3</sup> and lately Roth and Watson<sup>4</sup> have argued that there is no typical blood picture. However, Falconer,<sup>5</sup> Boles<sup>6</sup> and Muller and Boles<sup>7</sup> agree that the blood picture is characteristic and is of distinct aid in diagnosis.

In his series of cases Bunting noted no marked reduction in white blood cells, the lowest count in his group being 3,400. Fabian<sup>8</sup> noted a leukopenia in one fifth of the cases he reported. A review of the literature reveals only a small number of cases on record in which there had occurred a marked leukopenia. Of these, it may be seen, a number can be excluded because of high voltage roentgen therapy or coexistent disease of another nature that could also produce leukopenia. Mellon<sup>9</sup> has reported a case of Hodgkin's disease presenting moderate anemia and a severe leukopenia. The white blood count in this instance reached the low level of 800 cells. This case was purely Hodgkin's disease and no treatment that could possibly produce leukopenia was given. Miller<sup>10</sup> cites a case of Hodgkin's disease in which there developed an extreme leukopenia

with a reduction in white blood cells to 240 with a complete lack of granular cells and an accompanying anemia. This patient had received high voltage therapy. Gutig's<sup>11</sup> patient with a marked anemia and with a reduction of white cells to 680, of which 55.5 per cent were neutrophils, also had tuberculosis of the peribronchial lymph nodes and miliary tuberculosis of the spleen. Barron<sup>2</sup> has reported a case in which there existed a marked anemia and a leukopenia of 250 cells. This patient had received roentgen therapy over a long period of time. In Pilkington's<sup>12</sup> case the leukocytes dropped to less than 50, but here also high voltage therapy had been administered. Weber's<sup>13</sup> patient with a reduction to 900 cells had received radium therapy previous to the development of leukopenia. In Cooper's<sup>3</sup> paper there is reported a case in which the white blood cell count had fallen to 900 cells and in this instance there had been no previous therapy. At the Société médicale des hôpitaux of Paris<sup>14</sup> there has recently been reported a case of Hodgkin's disease in which the red blood cell count was 1,500,000 and the white blood count 1,600 cells but which had been preceded by high voltage roentgen therapy. Of these reports found in the literature in which there were noted instances of extreme leukopenia in Hodgkin's disease, high voltage or radium therapy had been administered in all but three. Of these three cases, there are two which were purely Hodgkin's disease. It is entirely probable that other cases in which there occurred an extreme leukopenia have been reported, but certainly it is obvious that the condition is rare enough to merit attention.

#### REPORT OF CASE

B. L., a white man, aged 37, a farmer, married and the father of three children, admitted to St. Luke's hospital Aug. 26, 1935, complained chiefly of "fever." In April 1935 he had been sick for about ten days with headache, fever, constipation and pain in the abdomen. In May of that year he again became ill with a cold, headache, fever and constipation. This attack lasted for two weeks. He was then in fairly good health, although somewhat weak, until August 22, when he again became ill with a cold, fever, headache, generalized muscular aching and a feeling of emptiness in the lower part of the abdomen. He also noted anorexia, occasional emesis and marked constipation. There had been a loss of 30 pounds (13.6 Kg.) since April 1935. History by systems revealed night sweats during the course of his illness, restlessness, and pains in the legs. The past medical history indicated that he had had a gonorrheal infection about fifteen years before, which had resulted in a urethral stricture. The important detail in the family history was that the patient's father died at the age of 51 years of pernicious anemia.

On physical examination the patient was well developed but thin. The skin was hot and dry and there was a café au lait color. The mucous membranes were pale. The pupils reacted to light and to accommodation. There were carious teeth. The lungs were apparently normal. The heart was normal. The pulse rate was 120 and regular. The blood pressure was 120 systolic and 70 diastolic. The abdomen was scaphoid and the spleen was distinctly palpable 1 cm. below the left costal margin. The cervical, axillary and inguinal lymph nodes were palpable but not enlarged. There was no sternal tenderness. Rectal examination and neurologic examination were negative. The temperature on admission was 103.4 F.

Laboratory studies included urinalysis, which showed 1 plus pus but was otherwise within normal limits. The red blood cell count was 2,780,000, hemoglobin 45 per cent and white blood cell count 3,400 with 69 per cent polymorphonuclear leukocytes, 22 per cent lymphocytes, and 9 per cent large mononuclear cells. Anisocytosis and poikilocytosis were present. In all, fifty-four complete blood counts were performed and are given in the accompanying tables. The bleeding time and coagulation time were found to be within normal limits. The platelets varied from 250,000 to 310,000. The icteric index was 6.7. Fractional gastric analysis after histamine showed no free hydrochloric acid and a total and combined acidity varying from 6.7 to 12 degrees. Examination of the stool was

due to the subcutaneous loculi of fat and actual nodulation of the anterior surface of the mammary gland. Even extensions of the gland parenchyma into the bases of the ligamenta suspensoria are clearly seen in the roentgenograms. This finding is probably the only roentgen sign on which to predicate a diagnosis of desquamative epithelial hyperplasia.

Whether a given nodule is solid or cystic from its roentgen appearance would seem to go unquestioned in some reports. It is claimed that a cystic tumor is more radiolucent than a solid tumor. The roentgen shadows of these two types of tumors do not differ as the shadows cast by transillumination. We have, however, made a successful differential diagnosis not by the differences in densities but by careful attention to a study of the margins. A cystic tumor, uncomplicated by perifocal inflammatory infiltration and not surrounded by too much active gland tissue, has a sharp, smooth and almost perfect circular margin, while a solid tumor, under the same circumstances, practically never has a perfect circular margin but always some eccentric bulge due to lobulation or some flattening or interaction of its periphery due to fibrosis.

On the whole, we believe that more accurate information concerning nodularity can be obtained from the roentgen examination, than from palpation, as happened in the following cases:

**CASE 4.**—The nodule visible in the left breast of the patient was palpable but felt smooth, freely movable and seemed benign. The posterior margins in the roentgenograms, however, were seen to radiate definitely into the parenchyma, and the roentgen diagnosis was malignant neoplasia. This was confirmed by histologic study done by Dr. Eugene Case (figs. 7 and 8).

Fig. 9.—The nodule in this breast was thought to be malignant because it was associated with fixation and puckering of the overlying skin. In the roentgenogram, the smooth margins and short pedicle were the reasons for assigning a benign basis to this growth.

tion by Dr. Dorothy Case Blechschmidt; after histologic study a fibro-adenoma with some cystic degeneration was disclosed (figs. 9 and 10).

#### SUMMARY

The roentgenographic examination of the breast is a more useful diagnostic procedure than is generally

appreciated. A diagnostic accuracy better than that resulting from macroscopic inspection of sections can be attained. A remarkably high percentage of roentgen diagnoses is proved to be correct by histologic studies, and this can be increased if the examination is more seriously and uniformly emphasized. Early malignancy can be very frequently determined, especially in the fat and postclimacteric breast. Otherwise there are many

Fig. 10.—Sections of the tumor in figure 9, a fibro-adenoma with cystic degeneration.

limitations to the roentgen study of the pathologic breast which probably could be materially reduced if resort were made to serial examinations.

If periodic examinations of normal breasts were carried out in women past 25 years of age, we venture to say that a much more effective campaign could be therapeutically waged in carcinoma of the mammary gland because of the diagnosis of early malignancy so obtainable. The examination can easily be done with so little expense that it is entirely practicable from these standpoints. It is even possible that the therapeutic effect on breasts of many endocrine substances might be revealed more graphically by the roentgen examination than by any other practical clinical method now available, and this suggestion warrants further investigation.

**To a Young Man of Good Disposition.**—This delicate word sickness includes drink, the contagious diseases, infant mortality, starvation, the sweating system, the immigrant alien, dangerous trades, insanity, childbirth, heredity, attempted suicide, accidents, assaults, and all the innumerable adventures, tragical or comical, which end in the Casualty Department. To a young man of good disposition, tired of the preliminary sciences and of humanity stated in terms of anatomy and physiology to the satisfaction of the examiners, this plunge into the actual flood of lives is a fine experience.—Paget, Stephen: *Confessio Medici*, New York, Macmillan Company, 1931.

127.8 / 100 / 450

Concentrated-Lilly) every other day. Curiously enough the red and white blood cell counts immediately began to rise coincident with a drop in temperature. After nine days of normal temperature a rise in the red blood cell count to 3,810,000, hemoglobin of 51 per cent, white blood cell count of 8,300, and a marked improvement in symptoms, he was discharged, September 12. One week later, September 19, he was readmitted with a recurrence of symptoms, a temperature of 102.4, a red blood cell count of 2,490,000, hemoglobin of 35 per cent, and a white blood cell count of 2,200 with 60 per cent

Chart 1.—Graphic demonstration of the blood counts. Only neutrophils, mononuclears and lymphocytes are included in the differential count in this graph.

polymorphonuclear cells, 37 per cent lymphocytes, and 3 per cent mononuclears. At this time there were occasional nucleated red cells and reticulocytes.

His course thereafter for a long time was fairly constant. There were periods of fever, which varied from 100 to 106 F. usually continuous in type but at times remittent, and lasting from seven to thirty-two days. The afebrile periods varied in length from three to eleven days. October 9 and 11 the white blood cell count fell to 900 cells with a serious reduction in the red blood cell count. Liver intramuscularly had been started at the time of his second admission but appeared to be of no value, and from October 9 to October 23 it is noted that he had an eosinophilia varying from 4 to 21 per cent. As he experienced chills and exacerbations of fever after the administration of liver during the latter part of the period of eosinophilia, it was felt that this was due to sensitivity to liver and it was discontinued. A sensitivity test was performed intradermally with liver but was negative. Pentnucleotide was given intramuscularly twice daily from October 8 to October 12, with a slight temporary rise in leukocytes. Four blood transfusions, the first of 400 cc., the others of 200 cc., were given on October 8, 10, 12 and 29. It is noted that on the days after all but one of these transfusions there was a reduction in the white blood cell count. During his course, sternal tenderness developed. A hypostatic pneumonia also developed, from which he recovered. However, he became progressively weaker and cachectic, steadily lost weight, finally passed into a muttering delirium, and died December 7.

During the latter part of his illness, although a definite diagnosis could not be established, it was felt that this was a case of Hodgkin's disease involving the spleen, the abdominal lymph nodes and possibly the bone marrow. These conclusions were reached for two reasons: the first, an atypical Pel-Ebstein or Murchison type of fever; the second, the tendency toward an increase in mononuclear cells and polymorphonuclear cells.

Permission for autopsy was secured and was performed by Dr. D. H. Kaump of the Mayo Clinic. His report follows: The unembalmed body, 163 cm. in length, was estimated to

weigh 125 pounds (56.7 Kg.). There was no edema or obesity. There was a grade 1 jaundice and grade 2 emaciation. Both pupils measured 0.4 cm. There was a small scar 3 cm. in length over the anterior portion of the sternum. When the peritoneal cavity was opened, the omentum lay free. There was no free fluid. The coils were smooth and glistening. The epiploic foramen was open and the duodenal folds were present. The liver margin projected 3 cm. below the right costal margin. The diaphragm arched to the fifth rib on both sides. When the pleural cavity was opened, 200 cc. of clear yellow fluid was found in each side. There were a few dense old adhesions at each apex. The transverse pericardium measured 15 cm. and there was 400 cc. of clear straw colored fluid in the sac. The thymus was apparently replaced by fat. The heart weighed 350 Gm. and was a reddish brown with normal fat and no soldier's spots. The consistency was diminished (grade 2). The cut surface was reddish brown and the septum showed no streaking. The appendages, endocardium and valves were normal. The foramen ovale was closed. The coronary arteries showed sclerosis (grade 1). The valve measurements were as follows: aortic valve 6.5 cm., mitral valve 11 cm., tricuspid valve 14 cm. and pulmonary valve 8 cm. On examination of the lungs the right upper lobe was a gray blue with anthracosis (grade 2) and apical scarring (grade 1). There was no atelectasis and the consistency and crepitation were normal. The cut surface was bluish gray and showed normal frothing and no edema. The right middle lobe was essentially the same and the right lower lobe was essentially the same except that the cut surface showed an increase in edema (grade 2). The left upper lobe was essentially the same as the right upper lobe. The left lower lobe was essentially the same as the right lower lobe. There was a diffuse emphysema (grade 2) throughout both lungs. The bronchi and vessels appeared to be normal. The spleen weighed 440 Gm. and was a mottled reddish purple and grayish red. There was an increase in lobulations (grade 2) and no perisplenitis. The consistency was normal and the wrinkling was diminished (grade 2). The cut surface was mottled reddish purple and grayish red. There was an increase in trabeculations (grade 1) and follicles (grade 2). There was a large number of these small grayish red areas of hyperplasia. The liver weighed 2,200 Gm. and was a light tan with a smooth surface and normal consistency. The color of the cut surface was light tan and mottled, with numerous small reddish hemor-

Chart 2.—Although not exactly coinciding, the rise in temperature and fall in red and white blood cell counts and the reverse procedure are shown. Circles denote temperature, x's red blood cells and solid dots white blood cells.

rhagic areas. The markings were distinct. The gallbladder contained 30 cc. of dark greenish black viscid material but was normal. The bile ducts were patent and showed no dilatation. The esophagus was normal except for a number of small linear hemorrhagic areas in the middle third. The stomach, duodenum, jejunum, ileum, colon and rectum appeared to be normal. The pancreas was estimated to weight 100 Gm. and appeared to be normal. Both adrenals were normal. The right kidney weighed 200 Gm. The capsule stripped with difficulty from a translucent light gray surface on which the lobulations and stellate veins were normal. There were no adenomas,

this test if they were colored to indicate that they had attained their best quality when as a matter of fact they were picked before they had attained their best quality. [We believe this date has since been put forward.]

Further information obtained from other sources relative to the handling of California oranges follows:

The spray used in the orange groves is an oil spray; a highly refined petroleum oil known as cosmetic oil. There is also some sulfur used in dusting. The petroleum oil penetrates the skin of the orange and there is undoubtedly still some of it present in the peel. There is no lead arsenate used in California. They have been trying out a spray of calcium chloride and selenium. This has been experimental only and probably very few of these oranges have been marketed in New York. They have been experimenting in Berkeley with "felocide," made up of selenium and sulfur. This is not in commercial use as yet. The oranges are all washed with a very good quality of soap and they are rinsed and dried before packing. A very few oranges are waxed. This is done with a wax made from the leaves of a palm that grows in South America and is much like paraffin. In the washing of the oranges there is a little borax used, which is rinsed off. There is about 0.01 per cent of this which remains in the peel, as measured in terms of boric acid. There is no artificial color used on California oranges. The only artificial coloring done at all is by sweating them with ethylene gas. A few sprayers have used a very small amount of creosol. However, the Orange Exchange discourages the use of any creosol in the spray. Lately they have been experimenting with sulfide of fatty alcohols.

\* The fruits used in tests 9 and 10 were picked from the tree in Florida and shipped directly to us.

This represents only a small fraction of information on some of the many and varied processes to which the citrus fruits are subjected today. We found it exceedingly difficult to get reliable information on the various processes from any source. Each grower employs a slightly different method from the next, and all the procedures are subject to frequent changes in each of the groves. There is a definite reluctance in many instances to give information that would prove helpful

in an investigation of this kind. All these factors probably play their part in accounting for the positive patch tests obtained from presumably undyed and untreated California oranges (to be mentioned in detail later) when known undyed and untreated Florida oranges gave negative results and the patient also reacted negatively to the oil of orange and lemon.

man, aged 31, a fruit and vegetable handler, whose family history was irrelevant except that his mother had diabetes, had his first skin eruption in 1929, which consisted of a slight irritation of the hands and face, lasting a very short time. In 1932 he developed a more severe irritation of the same areas and at the time the eruption was attributed to the arsenic used on the fruits and vegetables he handled. He was found to have excessive amounts of arsenic and lead in the urine and he was positive to lead arsenate and arsenic trioxide by patch tests. He had frequent attacks of diarrhea, nausea and vomiting. Several months later, when this eruption had cleared up, patch tests with sodium and lead arsenate were repeated and found to be negative.

Laboratory reports on this patient were as follows: The blood Wassermann reaction was negative. Routine examination of the urine gave negative results. The lead content was 0.016 mg. in 1,000 cc.; arsenic, 0.140 mg. per hundred grams of solids. The basal metabolism was —11.6.

Blood examination revealed 4,530,000 erythrocytes; 83 per cent hemoglobin and 5,800 leukocytes, the differential count being polymorphonuclear neutrophils 44 per cent, lymphocytes 50 per cent, eosinophils 5 per cent and basophils 1 per cent. Chemical tests revealed: urea nitrogen 14.9 = 13.9, sugar 79 = 100.4, uric acid 1.86 = 2.35, chlorides 466.8 = 441.8, and carbon dioxide 64.8.

The present trouble began in April 1934 with a severe erythematous, edematous, vesicular, weeping, crusting and scaling eruption covering the hands, face and neck. The eyelids were extremely swollen. The eruption came on while the patient was working in an open fruit and vegetable market.

Patch tests were made with the following substances to determine the cause of this irritation and were all negative: chlorox 10 per cent, Colgate face powder, wife's face powder (Lady Esther), wife's lipstick (Regina), tooth paste (Colgate), Octagon soap, cold cream, boric acid ointment, Camay soap, petrolatum, cotton, chicken feathers, duck feathers, sheep wool, silk, goosefeathers and tobacco (Camel).

Fruit tests are given in table 1; dyes, fungicidal solutions, ripeners and preservatives in table 2.

property of sodium bicarbonate or magnesium oxide which stimulates the secretion of acid. If these alkalis, therefore, are administered in doses that will not produce complete neutralization, secondary stimulation of secretion need not occur.

#### CERTAIN METHODS OF INSTITUTING ANTACID TREATMENT

The Sippy treatment for peptic ulcer has as its basis an attempt at complete neutralization of the gastric acidity until healing occurs. The prevention of acid irritation of the ulcer is rational but it is well recognized today that complete neutralization is not necessary and often impossible and that ulcers may heal as well with moderate doses as with large amounts of alkalis. The Sippy powders consist of No. 1, which contains 0.65 Gm. of heavy magnesium oxide and 0.65 Gm. of sodium bicarbonate, and No. 2, which contains 0.65 Gm. of bismuth subcarbonate or calcium carbonate and from 1.3 to 2 Gm. of sodium bicarbonate. One criticism of the Sippy regimen is that the amounts of alkali administered are too large. In fact, some clinicians have discontinued the use of alkalis altogether, a procedure with which we are not entirely in accord because, even though one may dispute the healing effects of alkalis, there can be no doubt that by their use symptoms are relieved and the corrosive effect of the acid at least partly overcome. Others have criticized the use of alkalis on the basis that complete or partial reduction of acidity interferes with gastric digestion; but when one remembers that this interference is only temporary and that the small intestine is capable of continuing the digestion of the contents passed on from the stomach as it does in achylia gastrica, this criticism is without substantial proof. The Sippy plan is logical, since it is much more important to reduce acidity than it is to allow the acid irritation to continue. It would seem, therefore, that unless other means such as carefully managed diet could accomplish what alkalis tend to do, the latter are an important part of therapy in gastric disease.

The following modification in the Sippy powders has been recommended: No. 1 consists of 0.65 Gm. of sodium bicarbonate and 0.65 Gm. of calcium carbonate; No. 2 consists of 0.65 Gm. of calcium carbonate and 0.65 Gm. of Heavy Magnesium Oxide, U. S. P. If bowel action is normally regular or if there is a natural tendency to diarrhea, the heavy magnesium oxide may be replaced by an equal amount of Bismuth Subcarbonate, U. S. P., or powder 1 substituted for powder 2. However, the Sippy powders can also be so regulated for, if diarrhea does develop, the second powder can be substituted for the first as often as may be required or, if constipation occurs, the opposite change can be made. Eusterman and Balfour recommend that one can readily substitute 1.3 Gm. of bismuth subcarbonate or 1.3 Gm. of sodium citrate, or the tribasic phosphates of calcium ( $\text{Ca}_3(\text{PO}_4)_2$ ) (Precipitated Calcium Phosphate, N. F.), 1.3 Gm., and magnesium ( $\text{Mg}_3(\text{PO}_4)_2$ ), 1 Gm., for the sodium bicarbonate in powder 1 whenever necessary if any unfavorable reactions occur that can be attributed to it.

Winkelstein has recommended a continuous alkalized milk drip into the stomach to maintain constant neutralization for twenty-four hours. He had demonstrated the high night acidity curves and this seemed a logical method of attack. The solution of milk contained 5 Gm. of sodium bicarbonate to the quart, regu-

lated as a drip so that the patient received 3 liters of milk and 15 Gm. of sodium bicarbonate a day. Theoretically this will neutralize 9 liters of tenth normal hydrochloric acid. Others before Winkelstein have stressed the importance of removing all acid contents from the stomach of the patient on retiring, by means of a stomach tube.

Wosika and Emery administered an alkalized (0.6 Gm. of calcium carbonate and 2 Gm. of sodium bicarbonate) powdered milk preparation every hour and found it somewhat more successful in neutralizing acidity than the usual Sippy plan. They believe, however, that in the majority of instances the Sippy plan produces complete neutralization but that when the acid was thoroughly controlled a greater quantity of alkali may have been administered than was needed.

Hurst considers milk the most efficient of all alkalis. He does not use the Sippy medication but adds 0.65 Gm. of sodium citrate with magnesia magma to each glass of milk not only because they are both efficient alkalis and neutralize any acid that is already present but also because the sodium citrate combines with the calcium of the milk and thus prevents the rennin from acting on the caseinogen. In this manner curds which act as a mechanical irritant to the ulcer are prevented from forming and the delay in stomach evacuation which might follow is avoided. His second mixture contains 0.3 mg. of atropine sulfate and this is administered twice daily, at 8 a. m. and 3 p. m. Sufficient magnesia magma is given to regulate bowel evacuation; at the same time it is a useful antacid. When heartburn or discomfort is present, 4 Gm. of prepared chalk is given between feedings. He believes that carbonates have the disadvantage of liberating carbon dioxide and he prefers not to use sodium bicarbonate because it produces an excessive rise in acidity after the initial neutralization. Interestingly enough, 15 Gm. of powdered charcoal with water is prescribed at 7 a. m. and in order to minimize the night acidity citrated milk is placed at the bedside to be taken if necessary. Hurst considers bismuth oxycarbonate completely inert and without alkalizing properties.

Crohn points out the familiar fact, with which we are in accord, that combinations of the various antacids

seem to exert a better effect than the individual preparations. For example, the rapid action of sodium bicarbonate is continued by the more slowly acting magnesia and bismuth, the latter of which Crohn writes are lacking in untoward secondary effects. For routine use he advises one of the combinations given in prescriptions 1 and 2.

In the first formula, oil of peppermint is added because of its pleasant taste and its carminative action on the gastric mucosa. However, Meyer, Scheman and

AMEBIASIS IN FOOD HANDLERS  
IN SAN FRANCISCOMARGARET KNIGHT IVERSON  
AND  
HERBERT G. JOHNSTONE, PH.D.  
SAN FRANCISCO

In this paper it is proposed to give completely the results of the survey for intestinal protozoa in food handlers conducted during the past three years in some of the hospitals, hotels, restaurants, clubs and lunch rooms of San Francisco. A preliminary report<sup>1</sup> has been published during the progress of this investigation. A total of 1,072 employees of public dining rooms and kitchens was examined and it was found that twenty-two, or 2.04 per cent, were infected with *Endamoeba histolytica*.

There were no fresh examinations of the stool specimens made, as it was thought that the most efficient method for disclosing protozoan infections with economy of time and labor was to make the fecal smears on the premises, directly after the passage of the stool, immersing them immediately in the fixing fluid. The smears, then brought to the laboratory, were stained by the iron alum-hematoxylin method and subsequently examined. Every employee was required to submit one specimen on each of three successive days. All those found to be infected with *Endamoeba histolytica* were compelled to stop work for not less than two weeks, during which period each infected person was given a course of treatments with carbarsone. These treated food handlers were then checked by three successive

daily stool examinations and were allowed to return to their employment when found negative. Each person was reexamined every two weeks for a period of three months. There were no cases resistant to treatment and there were no reinfections or relapses during these follow-up periods.

From the Pacific Institute of Tropical Medicine, Hooper Foundation, University of California.

In cooperation with Dr. J. C. Geiger, director of the Department of Public Health, San Francisco.

1. Johnstone, H. G., and Iverson, Margaret K.: Food Handlers and the Epidemiology of Amebiasis, *Am. J. Trop. Med.* 15:197-207 (March) 1935.

The results of the examinations of the entire food handling personnel of one hospital, one health home, five hotels, four clubs, four cafeterias, two restaurants, two grills and three lunchrooms are given in table 1.

Of the twenty-two persons found positive for *Endamoeba histolytica*, eighteen had been born, lived or visited outside the United States. A notable feature in the histories of these twenty-two people is an almost complete absence of admitted symptoms, only nine complaining of any gastro-intestinal upset, as shown in table 2.

TABLE 2.—Positive Cases of *Endamoeba Histolytica*

Name	Age	Sex	Position	Residence	Clinical History
1. E. E.	36	♀	Waitress	U. S.	None
2. W. P.	40	♂	Cook	Canada and U. S.	None
3. G. H.	40	♂	Baker	Germany and U. S.	None
4. G. S.	40	♂	Waiter	Greece and U. S.	Slight intestinal upset in August 1933; no medical care
5. P. M.	28	♂	Waiter	Italy and U. S.	Constipation
6. B. A.	36	♂	Waiter	Italy and U. S.	Occasional diarrhea
7. S. D. B.	31	♂	Waiter	Italy and U. S.	None
8. H. B.	29	♂	Bus boy	Turkey, U. S., Mexico	Under treatment in 1930 in Mexico City for loss of appetite and abdominal pain; no further illness
9. A. P.	42	♂	Waiter	U. S.	None
10. J. S.	50	♂	Steward	U. S. and So. Africa	Diarrhea while en route to Capetown in 1933
11. P. D.	49	♂	Second cook	France and U. S.	None
12. J. R.	31	♂	Waiter	Switzerland and U. S.	Had occasional diarrhea
13. M. D.	50	♂	Pot washer	France and U. S.	None
14. A. R.	25	♂	Bus boy	Italy and U. S.	Treated during 1933 for gas
15. P.	28	♂	Bus boy	Italy and U. S.	None
16. F. G.	63	♂	Waiter	Italy and U. S.	None
17. T. S.	40	♂	Cook	Yugoslavia and U. S.	None
18. T. C.	59	♀	Assistant manager	U. S.	None
19. E. Z.	24	♂	Dish washer	U. S.	None
20. C. R.	28	♂	Dish washer	Mexico and U. S.	Intestinal disturbance in 1928; medical care; no history available
21. J. K.	50	♂	Baker	Germany and U. S.	Diarrhea and stomach upsets
22. J. G.	38	♂	Supply boy	Scotland, China, Russia and U. S.	None

During the progress of the food handler survey, the Public Health Department of San Francisco conducted a companion survey to establish the exact plumbing efficiency of the hotels. This investigation was incomplete but in all hotels where the plumbing was inspected it was found that back siphonage (causing the contamination of water supply) is prevented by the maintenance of an adequate water pressure.

There has been little evidence to prove or disprove a direct contamination of food under practical conditions by food handlers. Hands, debris under finger nails and nail parings were examined after defecation and before the hands were washed in a group of seventy-four infected persons by Spector, Foster and Glover.<sup>2</sup> In only five of those examined were the cysts of *Endamoeba histolytica* found, two showed very few live *E. histolytica* large cysts, one showed very few dead *E. histolytica* large cysts, and two showed live small cysts. These observations along with those noted in the previ-

2. Spector, Bertha K.; Foster, J. W., and Glover, N. G.: *Endamoeba Histolytica* in Washings from the Hands and Fingernails of Infected Persons, *Pub. Health Rep.* 51:163-165 (Feb. 8) 1935.

The symptoms of discomfort or distention may be caused by a purely functional disturbance or it may be due to ulcer, as it commonly is, to cancer or to an inflammatory condition such as gastritis. In any event, antacids bring relief even though it is well recognized that they may only temporarily change the acid content of the stomach. Nevertheless, temporary relaxation of spasm or neutralization of acidity must be of therapeutic value in the healing of ulcer or gastritis or the various spastic conditions. Sodium bicarbonate, although the most commonly employed alkali, has been overused and therefore abused in the treatment of these conditions.

As has already been mentioned, the use of antacids in peptic ulcer is generally accepted not only as a means of neutralizing acidity but also to prevent the irritation and digestion of tissues. It is also essential to continue at least temporarily some form of antacid therapy of those patients who have been operated on. There are many reasons for this caution just as there are reasons for continuing antacid treatment in patients whose ulcers have apparently healed under medical management. There may not be an entire agreement regarding this point, but those who control their ulcer cases with diet alone are far fewer than those who cling to a rational antacid supplementary therapy.

In chronic alcohol gastritis, catarrhal duodenitis and other subacute and chronic gastric catarrhal conditions with excessive mucus formation, a mixture of sodium bicarbonate and sodium phosphate given in hot water about one hour before meals has been recommended. Bourget's mixture is also beneficial in these cases. In gastric hypersecretion, antacids give temporary but not lasting relief from symptoms.

Antacids are used in the gastric neuroses for the relief of heartburn, nausea, hyperesthesia or pain. The usual antacids, such as sodium bicarbonate or magnesium oxide, may be given in doses of from 0.3 to 0.65 Gm. or they may be combined with small doses of oil of peppermint. Bismuth subcarbonate and the neutral salts are also employed. Crohn recommends the preparation of magnesium superoxol, from 0.65 to 1 Gm., as a pleasant and convenient form of alkaline salt to administer. However, it has no advantage over other magnesium salts. Most antacids tend to relieve hyperperistalsis, irritability and spasm and so should be equally valuable in all dyspepsias, and especially in those which are associated with a high acid content, whether the hyperacidity is nervous or reflex in origin or whether it is associated with an ulcer or acid gastritis or whether it is unexplained.

#### MODE OF ADMINISTRATION OF ANTACIDS

As with other medicinals, there are rules which may be followed in order to administer alkalis properly. If the alkali is soluble it should be dissolved in water or if insoluble mixed with water before ingestion. When prepared in this manner its action is not too rapid and is probably far more soothing to the stomach. All alkalis should be prescribed in small or moderate doses, from 0.3 to 0.65 Gm., and should be administered not directly after the meal but between one and two hours later. Large doses are not more beneficial and only lead to overalkalinization with the secondary untoward reactions. Furthermore, relief of symptoms, intragastric tension and distention and spasm of the pylorus can be best obtained by the smaller doses. Given from

one to two hours after meals, that is, toward the end or late in the digestive cycle, alkalis are much less likely to cause a secondary hyperacidity and hypersecretion but, on the other hand, bring about not only a more efficient neutralization of acidity but also the relief of gastric discomfort or heartburn, which usually appear at this stage of the digestive cycle.

#### PRESCRIPTION 3.—Saline-Alkaline Mixture

℞ Sodium Bicarbonate .....	8 Gm.
Sodium Phosphate .....	4 Gm.
Sodium Sulfate .....	2 Gm.

Mix and pulverize.

Sig.: Dissolve powder in a liter (or quart) of cold water and sip slowly until relieved.

Crohn recommends the Bourget saline-alkaline mixture (prescription 3), sipped slowly, as an ideal method of administering alkalis by fractional dosage. The use of a mild aperient salt with an alkaline salt gives an added advantage by providing a laxative effect on the intestinal tract.

#### TYPES OF ANTACIDS

Thus far, most of our remarks have been general and have referred to antacids of the type represented by sodium bicarbonate. There are others, however, and some of them have been highly recommended for one reason or another. It is now our purpose to discuss these groups and then to refer again to sodium bicarbonate and its related alkalis for individual discussion.

*Aluminum Compounds.*—Two aluminum compounds, aluminum silicate and aluminum hydroxide, have been employed with apparently good effect, but these results require further confirmation before they can be finally accepted. The neutralizing effect of aluminum silicate is said not to have the disadvantage of producing a secondary rise in acid secretion and it does not cause gas formation as is occasioned by the carbonated alkalis. Systemic disturbances such as alkalosis do not occur. Colloidal aluminum hydroxide is supposed to act by colloidal-chemical absorption and not by chemical neutralization. It, too, produces no systemic reactions such as alkalosis or other toxic symptoms.

*Basic Phosphates.*—Greenwald in 1923 reported the gastric antacid effect of the dibasic and tribasic phosphates or calcium and magnesium. He also pointed out that since these substances are excreted in the stool and not in the urine they are not systemic alkalis. He regarded overalkalinization of gastric contents and urine as unphysiologic, and since sodium bicarbonate was known to produce these changes he did not consider it as an ideal antacid. Kantor used both the dibasic and tribasic phosphates and found the latter more effective. The calcium salts were slightly constipating and the magnesium salts slightly laxative, and the tendency of the patient to constipation or to diarrhea was recognized as a guide in the choice of the appropriate drug in any particular case. The dose of either compound was from 1 to 6 Gm., three times a day after meals. Kantor was able to conclude from his work that the common symptoms associated with hyperacidity (pain, heartburn, sour belching, distress and gas) were effectively controlled in most cases by these preparations and he thought that they were particularly useful in cases in which prolonged reduction of excessive gastric acidity was deemed advisable. Shattuck, Rohdenburg and Booker also reported favorably on these preparations and, in England, Hurst recommends them in certain cases.

negative for ova, parasites and occult blood. An x-ray film of the chest was essentially negative. X-ray examination of the stomach after a barium sulfate meal was negative. X-ray examination of the colon after a barium sulfate enema showed the descending colon to be narrow, smooth walled and with a loss of haustral markings. X-ray examination of all the long bones, pelvis and skull showed no evidence of bony pathologic changes. Blood cultures were repeatedly negative. Agglutina-

tion tests for typhoid, paratyphoid, *Brucella melitensis* and *Bacterium tularensis* were repeatedly negative. A skin test for tularemia was negative. A biopsy from the sternum was unsatisfactory and one from the left inguinal lymph nodes showed only chronic inflammatory changes.

Although a definite diagnosis was lacking, it was felt that a blood dyscrasia existed. The patient was empirically given liver extract intramuscularly (3 cc. of Solution Liver Extract

We have used prescriptions 7, 8 and 9.

**PRESCRIPTION 7.—Alkaline Peppermint Powder**

	Gm.
℞ Calcium Carbonate .....	1.3
Bismuth Subcarbonate .....	0.65
Magnesium Carbonate .....	0.3
Sodium Bicarbonate .....	1.0
Oil of Peppermint.....q. s.	

**PRESCRIPTION 8.—Small Powder**

	Gm.
℞ Sodium Bicarbonate .....	20
Calcium Carbonate .....	
Magnesium Oxide .....	4

Make twenty powders.

Sig.: One three times a day, one hour after meals.

**PRESCRIPTION 9.—Large Powder (for antacid and laxative effects)**

	Gm.
℞ Magnesium Oxide .....	15
Sodium Bicarbonate .....	90
Calcium Carbonate .....	15

Sig.: 4 Gm. in water three times a day, one hour after meals.

A useful preparation is the soda mint tablet (Tablets of Sodium Bicarbonate, N. F.), which contains sodium bicarbonate and oil of peppermint. The dose is from one to six tablets. The liquid form, known as the soda and mint mixture (Solution of Soda and Mint, N. F.) is also quite popular. It contains sodium bicarbonate 5 per cent and aromatic spirit of ammonia 2 per cent with spearmint or peppermint water. It is a mild antacid and carminative and may be given in doses of 8 cc.

Prescriptions 10 to 14 are commonly used.

**PRESCRIPTION 10.—Saline-Alkaline Mixture**

℞ Exsiccated Sodium Bicarbonate .....	
Exsiccated Sodium Phosphate .....	
Exsiccated Sodium Sulfate .....	30 Gm.

Sig.: One-half teaspoonful in water before meals.

**PRESCRIPTION 11.—Alkaline-Bismuth Subcarbonate Mixture**

	Gm.
℞ Sodium Chloride .....	2
Sodium Bicarbonate .....	
Kaolin .....	
Bismuth Subcarbonate .....	
Heavy Magnesium Oxide .....	15
Saccharin .....	0.065
Oil of Peppermint.....q. s.	

Sig.: One-half teaspoonful in water after meals.

**PRESCRIPTION 12.—Flavored Alkaline Mixture**

	Gm.
℞ Calcium Carbonate .....	
Tribasic Calcium Phosphate .....	
Sodium Bicarbonate .....	15
Saccharin .....	0.065
Oil of Lemon.....q. s.	

Sig.: One-half teaspoonful in water, one hour after meals.

**PRESCRIPTION 13.—Alkaline Gentian Mixture**

	Gm. or Cc.
℞ Tincture of Nux Vomica.....	12
Sodium Bicarbonate .....	12
Compound Tincture of Gentian.....	12
Peppermint Water, q. s.....	175

Sig.: 8 cc. three times a day in water, after meals.

**PRESCRIPTION 14.—Bourget Mixture**

	Gm.
℞ Sodium Bicarbonate .....	30
Sodium Phosphate (dry).....	
Sodium Sulfate (dry).....	15

(a) Sig.: From 4 to 8 Gm. in a glass of hot water on waking.

(b) Sig.: From 8 to 15 Gm. in a glass of hot water half an hour after meals.

The alkaline saline waters have been employed in the treatment of chronic gastric disturbances accompanied by hyperacidity. Of these Vichy, Carlsbad and Kissingen water are best known. As a general rule the

alkaline mineral waters contain only a small amount of the carbonate and are not to be preferred to pharmacopeial preparations.

One of the many useful drugs is aromatic spirit of ammonia. It is mentioned as a useful reflex stimulant, antacid and carminative. The dosage is 2 cc. freely diluted with water.

Among the official drugs used as gastric antacids are prepared chalk, compound chalk powder, chalk mixture, precipitated calcium carbonate, magnesium oxide, heavy magnesium oxide, magnesia magma, magnesium carbonate, solution of calcium hydroxide, aromatic spirit of ammonia, sodium bicarbonate and potassium bicarbonate.

**UNTOWARD REACTIONS OF ALKALIS**

1. *Alkalosis*.—Many instances have been recorded in which the administration of large doses of sodium bicarbonate has produced alkalosis with kidney injury and diminished excretion of nitrogen leading to uremia. Bastedo believes there is reason to suspect that in those cases in which alkalosis develops, abnormal factors of elimination and acid base metabolism may be present. Since alkalosis has not been detected following the administration of calcium carbonate or magnesium oxide it is suggested that as a precautionary measure these may be substituted for sodium bicarbonate in those cases in which large quantities of the latter have been used and the urine kept persistently alkaline.

As has been pointed out, the symptoms of alkalosis generally appear between the first and second week after the beginning of the alkaline treatment. As a precautionary measure the use of the tribasic phosphates of calcium and magnesium instead of other alkalis has been advised in those patients who have even a mild degree of renal disease or of pyloric obstruction. The tribasic phosphates act as local antacids without producing systemic alkalization. In all instances in which the slightest suspicion of the onset of alkalosis arises the regulation of alkali can always be guided by analyses of the plasma carbon dioxide. Since alkalosis has been most frequently observed in patients on the Sippy treatment or in cases of pyloric or upper intestinal obstruction accompanied by vomiting, such plasma determinations are extremely important when these conditions exist. Care must likewise be exercised in cases of hypertension and renal disease. Eusterman and Balfour called specific attention to the observation that ulcer-bearing patients who had chronic nephritis, pyelonephritis, hepatic cirrhosis, arteriosclerosis or hypertension were markedly susceptible to alkalosis.

Alkalosis is manifested by such symptoms as headache, drowsiness, anorexia, nausea, vomiting, muscle ache, nervousness, mental depression, vertigo and aching pain in muscles and joints. Tetany may develop. When such symptoms appear, administration of alkalis must cease at once and appropriate measures instituted to overcome the toxic state. In such cases some form of substitution therapy may be used instead of antacids. These are mucin, kaolin, alumina cream, colloidal kaolin and the tribasic phosphates used cautiously. With sufficient care, it is clear that alkalosis should be the rarest of complications in antacid therapy.

2. *Stone*.—Meyer and Singer reported a case of intermittent pyloric obstruction due to a gastrolith which consisted of magnesium and sodium, following treatment of ulcers with alkalis. This complication, however, is extremely rare.

scars or cysts. The consistency was normal. The cut surface was light gray and the markings were distinct. The cortex measured 0.5 cm. and the medulla 2 cm. The peripelvic fat was normal. The calices, pelvis and ureters were all dilated (grade 2). The left kidney weighed 210 Gm. and was essentially similar to the right. The bladder was empty at examination. It was somewhat contracted and thickened. The wall measured 8 mm. in thickness and was firm and fibrous to touch. There was a small amount of hemorrhage of the mucous membrane most marked in the area of the trigon. Both ureteral orifices were patent. The prostate measured 3 by 3 by 2.5 cm. and appeared to be normal on cut surface. The thyroid was normal in size and consistency. The aorta and its large branches were sclerosed (grade 1). The spine was normal in alignment. The periaortic lymph nodes were enlarged (grade 1). The largest of this chain of nodes measured 3 by 2 by 1 cm. These were fairly discrete and were of a light gray waxy appearance. The bone marrow was pyemia and semiliquid in consistency. The anatomic diagnosis was lymphoblastoma (Hodgkin's type); pulmonary congestion and edema with early diffuse bronchopneumonia; bilateral hydrothorax; contracted (grade 2) hypertrophied (grade 2) bladder with mural fibrosis, hydro-ureters bilateral (grade 2) and hydronephrosis bilateral (grade 2); emaciation (grade 2); arteriosclerosis (aorta grade 1, coronaries grade 1).

The report on the microscopic study will be limited to one of the lymph nodes from the abdomen: The normal structure was lost. There was a rather marked increase in the amount of connective tissue, much of which had undergone hyaline change. The remaining lymph spaces were filled with lymphocytes and a second type of cell which was large, slightly irregular and possessed a large pale nucleus in many of which there was a small deeply stained nucleolus. There was some increase in the size of the reticulo-endothelial cells. There were occasional multinucleated cells with a moderate amount of pale cytoplasm. There were occasional eosinophils and a few mitotic figures. The diagnosis was Hodgkin's disease. These slides were also studied by Dr. Arthur Wells of St. Luke's Hospital, Drs. Kernohan and Robertson of the Mayo Clinic and Dr. C. H. Bunting of the University of Wisconsin, all of whom agreed in the diagnosis. Microscopic sections of the spleen studied by Dr. Wells showed a diffuse moderate increase of the interstitial fibrous connective tissue. A few areas had a complete obliteration of sinusoids and much hyalinization, and others were comparatively free from fibrosis. There was a diffuse prominent eosinophilic infiltration throughout the sections. Rare giant cells of the Dorothy Reed type were noted. The diagnosis was Hodgkin's disease.

I sincerely regret that the specimens of bone marrow were unsatisfactory. Dr. Bunting also studied the blood smears and reported that the platelets were large, swollen and numerous.

This, then, represents a case of Hodgkin's disease diagnosed prior to death by reason of the atypical Pel-Ebstein fever and by repeated blood studies. Referring to table 2 it is noted that, in all, fifty-four blood counts were performed. I have already stated that the bleeding time, clot retraction time and clotting time were within normal limits. At times there was a considerable number of immature cells in both red and white groups. In the latter group these cells were members of the granular series. The anemia of 750,000 and 850,000 was extremely grave and with a hemoglobin of less than 10 per cent is worthy of mention. The platelet count, taken twice, varied from 250,000 to 310,000, and on constant study all smears failed to show any reduction in the number of platelets. Despite the absolute lack of mononuclears on occasion, it was felt that there was a tendency for these cells to be increased. If one adds the number of myelocytes and myeloblasts to the neutrophil count, it is found that the number of polymorphonuclear cells is quite above normal.

Chart 1 reveals these counts in graphic form and indicates the relatively high percentage of neutrophils and the tendency toward mononuclear increase and the progressive, severe anemia that existed. In chart 2 the interesting relationship between fever and blood count is observed. It was found that when the temperature rose above normal the red and white blood cell counts fell and, conversely, when the temperature returned to normal the blood elements increased.

## SUMMARY

A case of Hodgkin's disease was characterized by atypical Pel-Ebstein fever, a persistent and severe leukopenia and a steady and often extremely marked anemia; prior to death the physical changes gave no suggestion of Hodgkin's disease other than the palpable spleen. I wish to stress the point that had only one blood count been taken an antemortem diagnosis could not have been made. It is evident that the blood count could have been performed when the mononuclears were entirely absent or when they were increased, and also at a time when the immature cells could have led one astray. The continued study indicated a tendency toward an increase in mononuclear cells and polymorphonuclear cells. Also, although the number of platelets was not increased, it may be postulated that in comparison with the other formed elements they were relatively increased. I will make no effort to explain either the leukopenia or the anemia.

## CONCLUSION

It is felt that the blood picture is a distinct aid in the diagnosis of Hodgkin's disease and that in this condition, as in blood dyscrasias, a continued study of the blood is of extraordinary importance.

BALTIMORE

*This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.*

Antacids are employed primarily to reduce or neutralize the acidity of the gastric secretion, preferably by local action rather than through systemic alkalinizing effects. Gastric acidity is largely due to excess of free hydrochloric acid, but other fermentative acids may also contribute to its production. The condition may be recognized by an examination of the gastric contents or may be surmised from the symptoms noted by the patient. However, the ordinary test meal does not demonstrate excessive acidity as often as does the fractional test meal after the use of histamine.

## • IMPORTANT FACTS CONCERNING ANTACIDS

Hurst and Stewart point out that both sodium bicarbonate and magnesium oxide are the most powerful stimulants of gastric secretion known, with the exception of histamine. This is based on the work of Crohn and Reiss, who demonstrated by fractional test meals the primary neutralizing effect of these antacids followed by stimulation of acid secretion. It appears that since these alkalis produce an alkaline solution when given in excess whereas calcium carbonate, sodium and potassium citrates and tribasic calcium and magnesium phosphates produce a neutral solution, it is rather the alkaline reaction of the gastric contents than any specific

## WHAT IS AN AMERICAN?

The answer to the question propounded in the title is likely to reflect the narcissism or self idealization of the one who attempts to answer it. The physical anthropologist alone, however, according to a discussion by Hooton,<sup>1</sup> is qualified to view this question objectively and impartially. The anthropologist's data are derived from caliper measurements, indexes, morphologic observations and statistical analysis pertaining to masses of the population. His view, therefore, cannot be so easily affected by human frailty. When applied to civilized nations, in fact, anthropology has a distressing tendency to shatter cherished delusions.

Americans, for the purposes of Hooton's study, were divided into four classes: (1) old Americans, (2) new Americans, both of whom have been born to Americanism, (3) immigrant Americans—those who have achieved Americanism—and (4) Afro-Americans, or those who have had Americanism thrust upon them. The largest group of individuals used for the racial sorting of the survey was a criminal series composed of 5,689 inmates of penal institutions in nine states. The states were selected for the purpose of furnishing representative samples of all the more important racial groups domiciled in the United States. In addition, some 3,000 free citizens in and around Boston were measured to furnish a check sample. Anthropometric data were also compiled on about 6,000 visitors to the Harvard Model Laboratory at A Century of Progress Exposition in Chicago. The primary concern of all the observations was to determine the racial composition of the white population of the United States. The criteria used for the laboratory sorting method were primarily cephalic and combinations of hair color and eye color, combined in certain subgroups with a twofold division of stature or of the nasal index. Nine so-called racial types emerged in a relatively clear-cut fashion and could be statistically validated. These nine groups were (1) the pure Nordic type of pure blond long heads, (2) the pure Mediterranean type of pure brunet long heads,

(3) the predominantly Nordic type of near blond long heads, (4) the Celtic type of long heads with disharmonic pigment combinations, (5) the mixed Nordic Mediterranean type of long heads with intermediate but darkish pigmentation, (6) the East Baltic type of pure blond round heads with medium to broad noses, (7) the Alpine type of pure brunet round heads with medium to broad noses, (8) the mixed Nordic Alpine type of round heads with intermediate but lightish pigmentation and medium to broad noses, and (9) the mixed Dinaric type of round heads with intermediate pigmentation and narrow noses.

The proportions of the nine racial types in the three series—criminal, civilian check sample and world's fair visitors—were extraordinarily similar. The ranking physical type in the combined series was the Nordic Mediterranean group. It constituted about 25 per cent of the combined series, ranking first among the criminals and a close second in each of the two civilian series. It was strongest among the native whites of native parentage and seems to be a predominantly British type. Among the criminals it was remarkable because of its high ranking in first and second degree murder and its low ranking in burglary and larceny. In the two civilian series, those who belonged to this type were separated by a wide margin from the criminal group, both occupationally and educationally. The other physical types were similarly studied in some detail but cannot be cited here for lack of space.

As far as the data allow judgment, according to Hooton, the ethnic origins of the several types distinguished are identical or closely similar for the same types in all three of the series. The European antecedents, where ascertainable, confirmed anthropologic tradition as to the existence of certain physical races. No claim can be made, however, that these types constitute, singly, bodies of persons of exactly the same ethnic derivation. It is, however, a remarkable fact that the imperfectly segregated and classified physical types should exist in virtually identical proportions in these three widely divergent series. It is also clear that no anthropologic basis exists for singling out any so-called racial or national group, or religious or linguistic group, for preferment or for condemnation. Anthropologically it is much more rational to segregate and to eliminate the unfit, worthless, degenerate and antisocial members of each racial and ethnic strain in our population so that the substantial merits of the sound majority of each and the special and diversified gifts of its superior members can be utilized.

Professor Boas,<sup>2</sup> who has long been a student of this subject, has recently written briefly on the effects of American environment on immigrants and their descendants—a subject both closely allied to and indistinguishable from the question asked by Professor Hooton. The problem, Boas states, involves the answer to

1. Hooton, E. A.: What is an American? *Am. J. Phys. Anthropol.* 22:1 (Oct.-Dec.) 1936.

2. Boas, Franz: The Effects of American Environment on Immigrants and Their Descendants, *Science* 84:522 (Dec. 11) 1936.

Necheles have pointed out that oil of peppermint when used by itself or with a secretory stimulant depresses or inhibits the secretion of acid by the stomach.

#### GENERAL DISCUSSION OF ALKALIS IN ULCER CASES

As a rule some form of alkaline therapy is indicated in the treatment of peptic ulcer. Usually sodium bicarbonate combined with either bismuth subcarbonate or calcium carbonate or magnesium oxide (heavy or calcined) is prescribed. As we have already pointed out, however, caution must be taken in the use of large doses of these remedies since toxic effects may result after their absorption. Many clinicians are definitely opposed to the use of sodium bicarbonate or magnesia in doses exceeding 0.5 Gm. of either of the ingredients. Furthermore, Crohn has shown experimentally that large doses of alkalis neutralize or depress acidity only temporarily (from a quarter to half an hour), being followed by a secondary hypersecretion of gastric acidity that more than counterbalances the primary neutralizing effects. It is for this reason that the use of neutral salts such as the tribasic phosphate of calcium and magnesium have been recommended because they are not systemic alkalis but act rather locally in the stomach as antacids. They can therefore be used continuously without giving rise to toxic effects, since they are excreted in the intestine and produce no changes in the urine or blood. Moreover, they afford a degree of relief from symptoms in ulcer cases equal to that obtained by the more frequently used soluble and absorbable alkalis. On the other hand, it must be stated that others do not consider neutral salts as having any superiority over the ordinary alkalis. Perhaps no general rule can be formulated in antacid therapy. In our experience, certain individuals have responded to one type of therapy whereas other types have not been given relief. In rare instances, alkalis seem to aggravate rather than relieve the patient's symptoms.

#### EFFECTS AND MODE OF ACTION OF ALKALIS

Cushny considers that alkalis have no effect whatever on the activity of the secretory glands of the stomach as far as inducing a more rapid secretion of gastric juice is concerned. However, alkalis may affect the juice already secreted, rendering it neutral or even alkaline and, moreover, useless for digestion and disinfection. Nevertheless they are of benefit in cases of hypersecretion because they lessen the amount of free acid present. Dilute solution of the alkalis may overcome pain, eructations and distention by acting as slight irritants to the stomach wall and in this manner increase circulation. This carminative action may be strengthened when carbonates or bicarbonates are employed, owing to the liberation of carbonic acid by the action of hydrochloric acid. Alkalis may also help to render mucus less tenacious and apparently have definite effects on the movements of the stomach. Ordinarily excess of alkali is rapidly excreted in the form of alkaline salts. Nevertheless sodium bicarbonate, which is the most frequently used antacid, may produce alkalosis if given too frequently or in too large doses; and particularly in those cases in which pyloric obstruction or impairment of kidney function is present, constant care must be taken in order to avoid the production of any toxic effect.

Alkalis given with meals, i. e., during the digestive period, do not influence the acid secretion, although if given in large enough quantities they may render the

gastric contents alkaline and interfere with gastric digestion. During the period of digestion, however, the presence of food prevents acid irritation; but the presence of alkalis, such as sodium bicarbonate, will later give rise to higher acid values than would be present when this alkali is not taken. Even smaller amounts of alkali may diminish gastric activity by reducing the amount of free acid below the optimum concentration. As Bastedo points out, "it seems that we are dealing with a quantitative chemical neutralization made difficult by the attempt of the stomach to secrete more acid in order to accomplish its digestive function and this in turn requires more alkali. How much alkali is required depends also on the phase of digestion, for there is more acid present at the height of digestion than earlier or later in the digestive process." Bastedo also discusses the importance of the volume of contents in determining the effect of any antacid. The loss of contents through the pylorus as well as the fact that acid is continually being secreted while the amount of alkali is fixed also must be given consideration in determining the effect of a particular antacid. Since the presence of food combines with and absorbs acid, a high acid content may not be productive of symptoms during the digestive period, whereas even a lower level of acidity at the end of digestion may give rise to very distressing symptoms. It seems clear, therefore, that the time for antacid administration is at the end of digestion and in actual practice it is at this period that antacids actually afford most relief. It is believed, Bastedo points out, that the relaxation of the pyloric and cardiac sphincters after the administration of sodium bicarbonate, resulting perhaps from the liberation of carbon dioxide, is an important factor in overcoming acidity, hunger or empty pain. Perhaps this also explains why alkalis are also beneficial even when excessive acidity does not exist.

Meyer and Rubin carried out experiments on the effect of alkalis on experimental ulcer produced by Mann's method and were unable to support the view that alkalis are a factor in aiding the healing of ulcer. On the other hand, Dragstedt and Vaughan found that alkalis in amounts sufficient to neutralize the gastric secretion promote the healing of experimental gastric ulcers produced by a method different from that used by Mann.

#### INDICATIONS FOR ANTACIDS

Antacids are used primarily to neutralize excessive acid secretion in the stomach. In this way they relieve discomfort and perhaps also diminish the tendency to the development of peptic ulcer. Any mild antacid may be used for this purpose, but the many disadvantages of sodium bicarbonate have already been noted. Magnesium carbonate or soda may be used if a mild laxative action is needed; and if general stimulation is desired, such as in sudden "sour stomach" with headache as well as nausea, aromatic spirit of ammonia is useful. Belladonna and atropine are of value in hypersecretion, especially when the latter is associated with pylorospasm.

Since antacids are so commonly employed for relief of stomach discomfort, it seems logical that they should be administered just preceding the occurrence of pain if this is periodic. If the time of onset of pain cannot be judged, the antacid should be taken simultaneously with its onset. During the digestive period or toward its end, antacids may be beneficial if the discomfort is due to food irritation, distention or pylorospasm.

further course of atelectasis, according to Coryllos, will depend on the duration of the obstruction and the virulence of micro-organisms contained in the mucous exudate causing the obstruction. The presence of virulent pneumococci will cause pneumonia; the presence of pyogenic organisms may lead to suppuration and the presence of certain fusiform anaerobes to gangrene of the lung. Thus, atelectasis, either patchy, involving small areas or massive, is the forerunner of postoperative pneumonia or bronchopneumonia.

While most clinicians will not accept the theory that pulmonary atelectasis and postoperative pneumonia are two phases of essentially the same process, it appears reasonable to assume from the mass of accumulated evidence that atelectasis is the predominant postoperative pulmonary complication. And since the reduction of the vital capacity and interference with pulmonary ventilation are the two important factors in its production, the prophylaxis as well as the active treatment of the condition is clearly indicated. Among such measures one may mention the preoperative determination of the vital capacity, and in the postoperative period frequent change of posture, pulmonary exercises, hyperventilation with carbon dioxide inhalations suggested by Henderson, judicious administration of sedatives and narcotics sufficient to allay the pain but not to inhibit the cough reflex, avoidance of tight bandaging, and getting the patient up as soon as possible.

### *Current Comment*

#### GEORGE W. MCCOY AND THE U. S. PUBLIC HEALTH SERVICE

The Serums and Vaccines Act of 1902, with subsequent amendments, placed in the hands of the Hygienic Laboratory (now known as the National Institute of Health) the control of serums and vaccines sold in interstate traffic. The medical profession has benefited greatly by this work throughout the years, and especially by the services of Dr. George W. McCoy, its director for more than twenty-one years. Now comes the news that there has been an alteration in the administrative organization of the Scientific Research Division of the Public Health Service which directs such activities as do not conveniently come under the scope of the National Institute of Health. With the increase in scope of the investigative activities, all the research work of the service will be consolidated under the National Institute of Health. As a result of this reorganization, the chief of the Division of Scientific Research, Assistant Surgeon General Lewis R. Thompson, automatically becomes the director of the institute. To Dr. Thompson the change will not be great; in his capacity in charge of all the research work of the Public Health Service he has had intimate contact with the affairs of the laboratory. It is understood that the National Institute of Health is planning the establishment of a center for Public Health Service research

activities at Bethesda, Md., and that the plans for the center are maturing rapidly. The change brings the opportunity for Dr. George W. McCoy to return to his favorite study of leprosy, with which his name has long been identified as an investigator. Dr. McCoy has served on international commissions with distinction and has been showered with honors recognizing his value as a bacteriologist and administrator. It requires one of unusual talents to occupy an administrative position that involves direction of research work and at the same time supervision of commercial concerns. In his years with the Public Health Service, Dr. McCoy not only has maintained his high prestige as a research worker but has inspired the manufacturers of biologic products with high regard for the fairness of his decisions and for the efficiency of his department. Dr. McCoy has been a most valuable and cooperative member of the Council on Pharmacy and Chemistry since 1916. *THE JOURNAL*, speaking for American medicine, expresses to Dr. McCoy its best wishes as he returns to the field of pure science, in which he has already made many noteworthy contributions.

#### BRITISH COLUMBIA PHYSICIANS REJECT SICKNESS INSURANCE

A letter from A. J. MacLachlan, M.D., registrar of the College of Physicians and Surgeons of British Columbia, states that a ballot conducted among the members of the college on the question of whether or not they were in favor of working under the proposed plan of health insurance resulted in a vote of 619 against the plan and 13 in favor. The press announces that the premier, who was in Ottawa when the vote was received, wired instructions that collections under the act be postponed sine die and that the whole situation will be reviewed on his return from the East. This should suffice as a reply to those who said that the British Columbia scheme was adopted with the approval of the physicians of the province and that the first system of sickness insurance in North America was about to go into operation.

#### THE CULTS DEMAND NEW LEGISLATION

Congress and the forty-four state legislatures now in session, as will be seen under the heading Medical Legislation in the Organization Section of *THE JOURNAL* are busy with legislative proposals far more numerous than those in previous years. The causes of the deluge are obvious: Legislation is necessary to enable the states to avail themselves of the largesses offered by the federal government through the Social Security Act. The economic and social upheavals caused by the depression call for corrective measures. Outmoded and otherwise inadequate legislation needs revision. Tremendous problems with respect to revenue demand attention. Intelligent action on these matters will require all the time of the various legislative bodies. What mockery to have the cult practitioners of the healing art interject their selfish proposals at such a time. Possibly they do so in the hope that busy legislatures will pass without adequate discussion measures that will especially

**Bismuth Compounds.**—Crohn believes that bismuth salts, especially bismuth subcarbonate, although not alkaline in themselves, may be considered as a form of antacid therapy because by actual observation after test breakfasts he observed a depression of acid secretion in most cases. Bastedo, however, believes that the action is a demulcent and protective one, for bismuth salts either take up no acid or combine too slowly to have any gastric antacid effect. Notwithstanding this, bismuth salts are used to lessen hypersecretion and as a demulcent in peptic ulcer cases and also to check nausea, vomiting and gastric irritation. When it is employed in too large doses or over too long a period, bismuth becomes constipating and sometimes when not controlled the degree of constipation may become extremely distressing.

The usual dosage of bismuth salts, subgallate, subcarbonate and the much less used subnitrate because of its toxicity, is from 0.65 to 2 Gm., and magma of bismuth, 4 cc. Hurst directs attention to the fact that 0.3 per cent of hydrochloric acid has no action whatever on bismuth oxycarbonate, which indicates that it cannot possibly exert any neutralizing action on the acid gastric contents. He would therefore discourage its use not only because it has no neutralizing effect but also because it has the disadvantage of rendering the stools black, so that the immediate recognition of slight melena by the patient is made impossible.

**Sodium and Potassium Bicarbonates.**—According to Bastedo, sodium bicarbonate is a weak antacid of its kind but is considered superior and most generally valuable because it is the physiologic alkali of the body. Furthermore, it is soothing to irritated tissues when administered in dilute solution, gives off the carminative and soothing carbon dioxide in the presence of acid, and leaves a weak acid and nonirritation solution of sodium chloride. It also seems to have a special power to relax the pylorus and possibly also the cardia and, being in solution, it may help to dissolve mucus. On the other hand, it may produce alkalosis if administered in large amounts. When administered in ulcer cases, for example, sodium bicarbonate gives immediate relief from pain in most instances. The rapid neutralization of acid, however, is followed by a secondary rise in secretion, as has already been discussed. It has also been pointed out that some of the relief brought about by sodium bicarbonate is due to the effect of distention of the stomach with gas. This, however, may be dangerous, as Hurst and Stewart point out, if an ulcer is near perforation. In moderate doses a mild yet rapid effect may be produced, without so many disadvantages. It is the only soluble antacid in common use for stomach conditions.

Potassium bicarbonate is much less frequently used. Both it and the sodium compound are classed among the "alkali carbonates and bicarbonates." The dose of each is 1 Gm.

**Magnesium Salts.**—Magnesium oxide is in itself insoluble. It has a laxative effect, which may be of value but prevents the administration of any but moderate doses. The official magnesium antacids are the oxide, carbonate and hydroxide. They all have considerable combining power for acid but are very weak alkalis. Nevertheless they are valuable aids in the treatment of peptic ulcer and hyperacidity. Magnesium oxide has nearly four and one-half times the neutralizing power of an equal weight of sodium bicarbonate.

Furthermore, the period of neutralization is prolonged when compared with sodium bicarbonate. There is also no evolution of gas and consequently no gastric distention. However, as with sodium bicarbonate there is a secondary rise in acidity following the initial neutralization.

The average antacid dose of magnesium oxide (light or calcined magnesia) is 0.25 Gm. There is also a heavy magnesium oxide. According to Bastedo, it does not hydrate readily and is thought by many to be of less value than the light magnesia but it is used in powder form because of its smaller bulk. Magnesia magma, or magnesium hydroxide, is administered in doses of from 4 to 10 cc., magnesium carbonate in 0.25 Gm. doses. Bastedo points out that in neutralizing power 1 Gm. of magnesium oxide is approximately equivalent to 2.5 Gm. of magnesium carbonate, 3 Gm. of calcium carbonate, 4 Gm. of sodium bicarbonate and 21 cc. of magnesia magma and that these amounts can neutralize 18 cc. of diluted hydrochloric acid or 600 cc. of gastric contents containing 0.3 per cent of hydrochloric acid.

**Calcium Salts.**—Both calcium carbonate (chalk) and magnesium carbonate belong to the group of "carbonates of alkaline earths." Calcium carbonate is also insoluble and has a tendency to constipate mildly. It occurs in two forms, precipitated calcium carbonate, a heavy fine powder, and prepared chalk. The dose of either is 1 Gm. It has been shown that calcium carbonate has two thirds of the neutralizing power of sodium bicarbonate and the advantage of not giving rise to any secondary hypersecretion. Loevenhart and Crandall consider that calcium carbonate is the ideal antacid for the following reasons: 1. When suspended in water it is neutral in reaction. 2. It is only a "potential" alkali but it neutralizes the gastric acid, forming calcium chloride and carbon dioxide. 3. It can be given almost ad libitum. If an excess is taken, it passes out in the feces. 4. It apparently has no effect on the activity of the bowel except that, if taken in excess, it increases the bulk of the stool. (Others believe that it has a slightly constipating effect.) 5. When taken in excess it will coat over ulcerated areas and may in this manner afford protection from the action of irritants.

#### PRESCRIPTIONS

In discussing the powders presented in prescriptions 4, 5 and 6, Rutherford-Darling cautions that if such

##### PRESCRIPTION 4.—Powder of Bismuth Carbonate and Chalk

Chandler, on "Medicine, Metaphysics, Psychiatry and Cults." Dr. Alexander D. Waroshill, Florence, presented a case report on "Hemolytic Degeneration of the Blood in a Case of Influenza."—Dr. Jack G. Hutton, Denver, discussed the diagnosis and treatment of the twelve most common skin diseases seen in general practice before the Arapahoe County Medical Society, Englewood, January 25.—The Medical Society of the City and County of Denver was addressed, March 3, by Drs. Harry Gauss on "Gastro-Intestinal Symptoms of Cardiovascular Origin"; Joseph R. Plank, "Mesenteric Lymphadenitis," and James R. Jaeger, "Newer Conceptions of Sciatica," with motion picture demonstration. Dr. Siegfried J. Thannhauser, Boston, conducted a diagnostic clinic before the society, February 2.

### CONNECTICUT

**Appointments to State Department of Health.**—Dr. Franklin M. Foote, Elizabethton, Tenn., has been appointed chief of the division of local health administration of the Connecticut State Department of Health. He succeeds Dr. Benjamin G. Horning, who was appointed health officer of Hartford. Dr. Martha L. Clifford, assistant director of the bureau of child hygiene, has been named director of the department, and Dr. Martha A. O'Malley, Waukon, Iowa, has been made a member of the bureau staff. Dr. Foote graduated from Yale University School of Medicine in 1933 and from the school of public health in 1935, and Dr. O'Malley took her medical degree at the State University of Iowa College of Medicine, Iowa City, in 1933. Dr. Clifford graduated from the University of Colorado School of Medicine, Denver, in 1933.

### DELAWARE

**Hospital News.**—The new \$104,000 addition to the Brandywine Sanatorium at Marshallton was opened January 25. Fully equipped, the new addition is valued at \$120,000 and provides accommodations for fifty new beds, making the total bed capacity of the institution 160.

### DISTRICT OF COLUMBIA

**Annual Graduate Clinic.**—The fifth annual graduate clinic of the George Washington University School of Medicine, Washington, was conducted February 20. The following program was presented:

- Dr. Roger M. Choisser, Sudden Death: A Clinical Pathologic Consideration with Case Presentations.
- Dr. William E. Clark, Duodenal Ulcer.
- Dr. Jacob Kotz, How to Examine a Female Endocrine Patient.
- Dr. Harry A. Davis, Cancer of the Thyroid.
- Dr. Elijah W. Titus, Practical Considerations in Gynecologic Practice.
- Dr. Walter A. Bloedorn, Relation of Clinician and Pathologist.
- Dr. Francis R. Hagner, Results in Operations for Sterility.
- Dr. William H. Jenkins, Autoplastic Facial Nerve Graft.
- Dr. Herbert P. Ramsey, Factors in Marital Pathology.
- Dr. Guy W. Leadbetter, The Mechanics of Traction in Fractures.
- Dr. George Louis Weller Jr., Treatment of the Anemias.
- Dr. William Ross Morris, A Method of Completing Unsuccessful Pneumothorax.
- Dr. Harry F. Dowling, Present Day Status of Pneumonia Therapy.
- Dr. Margaret M. Nicholson, Congenital Heart Disease.
- Dr. Samuel M. Dodek, Management of the Persistent Occipitoposterior and Arrested Transverse Positions.

### ILLINOIS

**Physicians Honored.**—The Madison County Medical Society conferred honorary membership on Drs. Adam H. Oliver, Edwardsville; Charles R. Kiser, Madison, and Leonard Schreifels, Granite City, at a recent meeting. All are 70 years or more of age. Dr. Schreifels was president of the society in 1929 and Dr. Kiser in 1919.

**Immunization of Parochial School Children.**—A campaign to immunize children against diphtheria was projected in eighty parochial schools in the diocese of Belleville by the school authorities and the Catholic Physicians' Guild. Children who paid no tuition were inoculated without charge, the others going to their family practitioners. The parochial school physician gave the free inoculations and supervised the program. In the future all children entering school for the first time will have medical examinations.

### Chicago

**Society Moves Offices.**—The Chicago Medical Society will have its headquarters in the Michigan Boulevard Building, 30 North Michigan Avenue, after April 1. The society will occupy four rooms on the fifteenth floor of the building.

**Malaria Traced to Narcotic Addicts.**—Six deaths from malaria have been reported among narcotic addicts since January 1, according to the newspapers. Investigation of the death from this cause of Earl Davidson, 27 years of age, in the County Hospital, February 8, revealed that he had served

a year in Leavenworth Penitentiary for possessing narcotics. At his home a hypodermic needle and narcotics were found. An outbreak of malaria among a group of narcotic addicts who admitted they used the same syringe was reported in *THE JOURNAL*, Feb. 9, 1935, page 481.

**Dr. Hektoen to Deliver First Fenger Lecture.**—Dr. Ludvig Hektoen will deliver the first Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society at a joint meeting with the Society of Medical History of Chicago and the Chicago Surgical Society, March 26. His subject will be "Early Pathology in Chicago and Christian Fenger." The lectureship has recently been established under the joint auspices of the institute and the pathologic society in honor of Dr. Christian Fenger, who was the first teacher of pathology in the Middle West. He was born in Copenhagen, Denmark, Nov. 3, 1840, and died March 7, 1902. He served as professor of clinical surgery at the College of Physicians and Surgeons, Chicago Medical College and Rush Medical College.

### INDIANA

**Secretaries' Conference.**—The annual conference of the county medical society secretaries will be held March 21. The conference was scheduled for January 31 (*THE JOURNAL*, January 16, p. 212), but was postponed because of flood conditions.

**Society News.**—Dr. Albert C. Furstenberg, dean, University of Michigan Medical School, Ann Arbor, discussed "Acute Infections of the Mouth, Throat and Cervical Region" before the Fort Wayne Medical Society, February 2.—Dr. Philip S. Hench, Rochester, Minn., addressed the Indianapolis Medical Society, February 23, on "Diagnosis and Treatment of the Various Types of Chronic Rheumatism."—Dr. John H. Warvel, Indianapolis, addressed the Northeastern Indiana Academy of Medicine in Kendallville, January 28, on "Protamine Insulin."

### KANSAS

**Cancer Control Program.**—The Kansas Medical Society will conduct its second annual program on cancer control, March 15-20. Sessions will be held for physicians in the evening and for the public in the afternoon in Emporia, Hutchinson, Garden City, Colby, Concordia and Kansas City. The speakers will be:

- Dr. Burton T. Simpson, director, New York Institute for Study of Malignant Disease, Buffalo, N. Y.
- Dr. Louis C. Kress, assistant director of cancer control at the institute.
- Dr. Frank L. Rector, Evanston, Ill., field representative of the American Society for the Control of Cancer.

Also cooperating in the series are the Northwest Kansas Medical Society and the Lyon, Reno, Cloud, Finney and Wyandotte county medical societies.

### KENTUCKY

**Special Studies in Mental Hygiene.**—The U. S. Public Health Service is making special studies of mental hygiene in Fayette and Scott counties with the ultimate object of determining whether the situations influencing the evolution of mental disorders group themselves into etiologic categories. Another objective is to determine whether there is a pattern approach to this problem from the standpoint of the place mental hygiene might occupy in a regularly constituted health organization. The work is directed by Dr. Lieuen M. Rogers of the U. S. Public Health Service and is conducted in cooperation with the state health department, the health departments of Fayette and Scott counties and the University of Kentucky, Lexington.

### MAINE

**Society News.**—Dr. Chester M. Jones, Boston, discussed "Treatment of Liver Disease" before the Cumberland County Medical Society, February 26.—At a meeting of the York County Medical Society in Sanford, April 7, Dr. Stephen A. Cobb will speak on the injection treatment of hernia.—The Kennebec County Medical Association was addressed in Waterville, February 18, by Dr. Frank B. Bull, Gardiner, on cancer and Drs. John O. Piper, Waterville, and Richard B. Cattell, Boston, on thyroid from the medical and surgical points of view, respectively.

### MARYLAND

**Personal.**—Dr. William J. French, health officer of Anne Arundel County, has been made an honorary member of the Howard County Medical Society.—Dr. Lewis H. Weed, professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, will deliver an advanced course of lectures in anatomy at the University of London this spring on "The Cerebrospinal Fluid."

Another rare complication is the precipitation of phosphatic stones in the urine following alkaline (sodium bicarbonate) therapy with the production of a persistently alkaline urine.

3. *Interference With Digestion.*—There has been much discussion concerning the unphysiologic action of alkalis which reduce gastric acidity and diminish or inhibit gastric digestion. This problem has already been discussed. Moreover, in ulcer cases in which duodenal alimentation is used the stomach does not participate in digestion. Furthermore, not only is digestion adequately carried on by the intestine alone but frequently gastric acidity is alkalized or neutralized by the oral administration of antacids. This is another proof that overalkalinization or neutralization need not be objected to on the basis of interference with gastric digestion.

4. *Sensitivity to Alkali.*—It has been recognized that some patients are sensitive to almost any alkali, whether systemic absorption occurs or not. On the other hand, neutralization is not readily effected in a certain number of cases, even with the addition of increasing amounts of calcium carbonate or other suitable alkali. In the latter instances the possibility of obtaining a cure is less favorable, yet healing of the lesion may be complete and permanent if the treatment is followed through thoroughly.

5. *Other Untoward Effects.*—The secondary rise in acid secretion following the primary neutralization brought about by certain alkalis has already been discussed. It has been suggested that a catarrhal gastritis may result from the hypersecretion thus produced, but this must be extremely rare if it actually does occur. Rehfuess suggests that excessive gastric secretion associated with night distress may be the result of overalkalinization, representing as it does chiefly the attempt of the stomach to produce acid sufficient to neutralize the enormous doses of alkali administered.

Tetany is also said to have been known to follow the therapeutic administration of sodium bicarbonate.

Finally, Eusterman and Balfour are of the opinion that intestinal irritation caused by the purging effect of magnesium or other alkalis with aperient quality may cause discomfort which is attributed to the ulcer. They also report that fecaliths and chalk balls may form in the sigmoid in cases of constipation in which large amounts of calcium carbonate are being taken of necessity. This gives rise to symptoms of anorexia, abdominal fulness and distress.

#### CONCLUSION

The important lesson to be derived from this discussion of gastric antacids is the availability of a group of accepted pharmacopeial drugs as well as a supplementary group of medicinals which can be used as substitutive therapy or to augment the desired therapeutic effect of the first group. It therefore becomes apparent that the physician can easily select any of these preparations and vary them according to the specific and individual need of each patient. For that reason, as well as for many others, we recommend that the physician take advantage of the opportunities offered by such sensible prescribing rather than to resort to the use of proprietary remedies, many of which are known to him only by their trade names, whereas the proportion of their ingredients as well as the ingredients themselves are often only vaguely given. Furthermore, such proprietary remedies do not permit of careful proportioning of ingredients to suit the needs of the individual patient.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

- (1) SECCO BRAND TOMATO JUICE
- (2) PRIDE OF EGYPT BRAND TOMATO JUICE
- (3) SWEET VIOLET QUALITY TOMATO JUICE
- (4) DEFENDER BRAND TOMATO JUICE

*Distributors.*—(1) Comstock Canneries, Inc., Newark, N. Y. (2) and (4) Egypt Canning Company, Inc., Fairport, N. Y. (3) Finger Lakes Canning Company, Inc., Pennyan, N. Y.

*Packer.*—Comstock Canneries, Inc., Newark, N. Y. (Factories at Egypt and East Pembroke, N. Y.)

*Description.*—Canned tomato juice retaining in high degree the natural minerals and vitamins. Seasoned with salt.

*Manufacture.*—Choice variety of field-ripened tomatoes are graded, washed, inspected and preheated. Juice is mechanically extracted, heated, salt is added, and the juice is filled into cans, which are exhausted, sealed and processed at 100 C. (Small plants are sprayed with Bordeaux mixture.)

*Analysis* (submitted by manufacturer).—Moisture 94.0-94.2%, total solids 5.8-6.0%, insoluble solids 0.1-0.5%, soluble solids 5.4%, ash 0.8-0.9%, fat (ether extract) 0.01-0.03%, sodium chloride, 0.7%, protein (N  $\times$  6.25), 0.9-1.0%, reducing sugars as invert sugar 4.1-4.4%, sucrose 0.0%, carbohydrates (by difference) 3.4-3.9%, acidity as citric acid 0.4-0.5%.

*Calories.*—0.18 per gram; 5 per ounce.

*Vitamins.*—Approximately 80 international units of vitamin C per fluidounce.

### SEXTON BRAND SPINACH, WATER PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned spinach, packed in water.

*Manufacture.*—Spinach crowns are cut for uniform stem length, washed, blanched, again inspected and hand filled in cans. The cans are filled with boiling water, exhausted, sealed and processed.

*Analysis* (submitted by manufacturer).—(Analysis of entire content including liquid): moisture 90.9%, total solids 9.1%, ash 1.2%, fat (ether extract) 0.3%, protein (N  $\times$  6.25) 3.5%, crude fiber 1.04%, carbohydrates other than crude fiber (by difference) 3.1%.

*Calories.*—0.29 per gram; 8 per ounce.

*Claims of Manufacturer.*—Choice quality spinach packed in water without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

### DAKOTA MAID FLOUR (BLEACHED)

*Manufacturer.*—State Mill and Elevator, Grand Forks, N. D.

*Description.*—A hard spring wheat "first patent" flour; bleached.

*Manufacture.*—Selected grades of North Dakota hard spring wheat are mixed, washed, dried, scoured, polished, ground thirty-two times, sifted and impurities are removed. The flour is bleached with benzol peroxide (one-half ounce per barrel) and nitrogen trichloride (1½ Gm. per barrel).

*Analysis* (submitted by manufacturer).—Moisture 15.0%, total solids 85.0%, ash 0.4%, protein (N  $\times$  6.25) 11.6%, fat (ether extract) 1.4%, crude fiber 0.3% and carbohydrates other than crude fiber (by difference) 71.3%.

*Calories.*—3.44 per gram; 98 per ounce.

Ossining, and Herman O. Mosenthal addressed the New York Endocrinological Society, January 27, on "Insulin Treatment of Schizophrenia" and "Protamine Insulin: Its Clinical Application" respectively.—At a meeting of the New York Surgical Society, February 27, Dr. Paul C. Morton spoke on "Carcinoma of the Rectum."—Members of the faculty of Temple University Medical School, Philadelphia, presented the program of the New York Cardiological Society, January 28, as follows: Drs. Charles L. Brown, on "The Urinary Cast Count in a Study of Mercurial Diuretics; Experimental and Clinical Observations"; Joseph B. Wolfe, "Angina Pectoris: Newer Therapeutic Approach" and William Wayne Babcock, "Surgical Treatment of Cardiovascular Diseases."

## OHIO

**Dr. John Honored.**—Dr. Henry J. John, Cleveland, received the Eisenman Award of the Cleveland Jewish Welfare Federation at the annual meeting of the organization February 4 in recognition of his work for diabetic children in Cleveland. Dr. John established a summer camp for these children at his estate in Geauga County several years ago, the first of its kind. The award of \$750 will be used for the camp, it was announced. Dr. John was graduated from Western Reserve University School of Medicine in 1916.

**Alumni Assembly at Ohio State.**—Medical conferences and a graduate assembly were presented at Ohio State University College of Medicine, Columbus, March 4-6, to celebrate the one hundred and third anniversary of the founding of Willoughby Medical College, the original school from which the present one developed. Thursday, March 4, was devoted to an open house at the college of medicine, during which demonstrations were open and physicians of the state were invited to confer with the clinical teachers. Friday a program was presented by numerous members of the faculty, and in the evening the Alpha Omega Alpha Lecture was given by Dr. Henry E. Sigerist, William H. Welch professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, on "Early Medical History in the United States." Saturday morning there were presentations at University Hall until 10:45 o'clock, when a new outpatient building was dedicated. Speakers at the dedication were Drs. Charles Gordon Heyd, New York, President of the American Medical Association; Gatewood and Arthur C. Bachmeyer, Chicago, and Charles W. McClure, Boston. Reunions and class luncheons were held at noon at the Deshler-Wallick Hotel. Dr. Henry W. Lehrer, Sandusky, president of the alumni association, presided and Drs. John H. J. Upham, dean of the college of medicine and President-Elect of the American Medical Association, and John B. Alcorn, Columbus, president-elect of the Ohio State Medical Association, were presented. Saturday afternoon the program was given at the St. Francis Hospital, with Dr. McClure as the guest speaker, on diseases of the liver. Arrangements for the meeting were made by Dr. Upham; Dr. Lehrer and other officers of the medical alumni association, and a committee of which Dr. Russel G. Means, Columbus, was chairman.

## PENNSYLVANIA

**Society News.**—Drs. Marc W. Bodine and Robert C. Bastian, Williamsport, addressed the Lycoming County Medical Society, Williamsport, February 12, on "Surgical Phases of Peptic Ulcer" and "Pathologic Conditions of the Paranasal Sinuses" respectively.—Dr. Guy M. Nelson, Philadelphia, addressed the Montgomery County Medical Society, Norristown, March 3, on "The Gallbladder Problem."—A symposium on therapeutics was presented at a meeting of the Fayette County Medical Society, Uniontown, February 4, by Drs. Ralph L. Cox, Star Junction, on drugs that induce sleep; John B. Hibbs, Uniontown, drugs that induce diuresis, and Charles Franklin Smith, Uniontown, drugs that relieve or prevent itching.—Dr. John Lansbury, Philadelphia, addressed the Lebanon County Medical Society, February 9, on diabetes.

### Philadelphia

**Dr. Sakel Lectures.**—Dr. Manfred Sakel, Vienna, Austria, gave a special lecture on "The New Insulin Treatment of Mental Disease" at the Institute of the Pennsylvania Hospital, February 19.

**Fire at University Hospital.**—Fire damaged severely the roof and the fourth floor of the D. Hayes Agnew Pavilion of the Hospital of the University of Pennsylvania, February 24. Seventy-eight patients were removed to safety and movable equipment was saved. It was estimated that the damage to

the building and heavy equipment was about \$100,000. The origin of the fire was not determined, but it was believed to be a short circuit in electric wiring.

**County Society Secretary Dies.**—Mr. Franklin M. Crispin, executive secretary of the Philadelphia County Medical Society for the past thirteen years, died February 7, aged 60. Mr. Crispin had been associated with the society for twenty-five years. He was a native of Philadelphia and attended Princeton University. He was at one time advertising manager of *Forum* and treasurer of the Philadelphia Grand Opera Company, according to newspaper accounts.

**Society News.**—Dr. George P. Müller has been elected president of the College of Physicians of Philadelphia; Dr. Edward B. Krumbhaar, vice president, and Dr. James Harold Austin, secretary.—The subject of discussion at the meeting of the Philadelphia County Medical Society, March 10, was "Abdominal Quadrants," with Dr. Eldridge L. Eliason speaking on surgical aspects and Dr. Edward J. G. Beardsley on medical aspects.—Drs. George M. Coates and William Gordon presented a paper on "Abscess of the Epiglottis" and Dr. Charles E. Towson, "Aural Complications of Pneumonia in Children" at a meeting of the Philadelphia Laryngological Society, March 2.—Speakers before the Philadelphia Roentgen Ray Society, March 4, were Drs. Richard T. Ellison, on "Mediastinal Hernia"; George J. Willauer, "Internal Pneumolysis in the Treatment of Pulmonary Tuberculosis," and Richard H. Meade Jr., "Value of the Roentgen-Ray Examination in Thoracic Surgery."—Dr. Baldwin L. Keyes, among others, addressed the Philadelphia Pediatric Society, February 9, on "Visceral Symptoms in Acute Anterior Poliomyelitis."

### Pittsburgh

**Society News.**—Dr. Gilbert J. Thomas, Minneapolis, addressed the Pittsburgh Urological Society, March 8, on "Genito-Urinary Tuberculosis."—At a meeting of the Women's Medical Society of Pittsburgh, February 23, Dr. William W. G. MacLachlan discussed pneumonia.—Speakers at the meeting of the Allegheny County Medical Society, February 16, were Drs. Stuart N. Rowe, on "Indications for Operation in Cases of Head Injury"; Joseph A. Soffel, "Resection of the Distal Colon for Malignancy," and Leon H. Hetherington, "Closed Intrapleural Pneumolysis as an Adjunct to Artificial Pneumothorax."—Dr. Claude S. Beck, Cleveland, delivered the Robert W. Stewart Memorial Lecture at the Pittsburgh Academy of Medicine, January 26; his subject was "Recent Developments in Surgery of the Heart."

## RHODE ISLAND

**Society News.**—Dr. William P. Buffum, Providence, addressed the Washington County Medical Society, Westerly, January 13, on "Allergy in Childbirth."

**Reference Required for Clinic Patients.**—The chief of the division of hospitals and infirmaries of the state department of public welfare has issued an order to the effect that no patient will be admitted to any outpatient clinic under the jurisdiction of that division without a written reference from a physician registered in the state.

## TENNESSEE

**Dr. Madsen Gives Flexner Lectures.**—Dr. Thorvald Madsen, director of the State Serum Institute, Copenhagen, Denmark, is in residence at Vanderbilt University School of Medicine, Nashville, to deliver the Abraham Flexner Lectures. He gave the first lecture March 10, on "Control of Venereal Diseases in Denmark, with Special Reference to Syphilis." Coming lectures are as follows:

- March 15, Mechanism of Bacterial Infections.
- March 19, Epidemiology of Tuberculosis.
- March 24, The Influence of Seasons on Infections.
- March 29, Whooping Cough.

Dr. Madsen has been head of the state serum institute in Copenhagen since 1902 and president of the hygiene committee of the League of Nations since 1921.

## TEXAS

**New Division in Charge of Eleemosynary Institutions.**—The state board of control has established a division of eleemosynary institutions in the state government; it is reported. Dr. Charles W. Castner, superintendent of the Wichita Falls State Hospital, was appointed chief of the division. Dr. Castner had previously been superintendent of the Terrell, Rusk and San Antonio state hospitals. Dr. Barton W. Dorbandt, assistant superintendent of the San Antonio State Hospital, has been appointed to succeed Dr. Castner at Wichita Falls.

two questions. Knowing the importance of heredity in determining bodily form and function, it is necessary to understand the composition of the immigrant and native populations and their biologic differences; furthermore, it is necessary to differentiate sharply between what is hereditarily and what environmentally determined. Populations have always moved from one climate to another, and distinct cultures have been thrown together. Even more important than the bodily effects of these changes, Boas believes, is the problem of hereditary determination of personality. One method of studying this problem is the proof by motion pictures of the inaccuracy of the common assumption that Americans do not gesticulate. This motor habit, and probably others, seems to be definitely allied to environment and is peculiarly unstable. The study of such peculiarities, he concludes, shows first of all that no race can be treated as a unit but that in every case the individual must be evaluated according to his own characteristics. As far as the aspects studied are concerned, the descent of the individual plays an insignificant part in his behavior, and the organism is so plastic that its physiologic, mental and social behavior follows the pattern of culture with which it becomes identified. It may be seen, therefore, as far as these two studies interlock in the indicated conclusions, that there is complete agreement concerning the lack of anthropologic support for any clear-cut division of characteristics by racial grouping.

#### THE RÔLE OF ATELECTASIS IN POSTOPERATIVE PULMONARY COMPLICATIONS

Postoperative pulmonary complications occur in from 2 to 4 per cent of all operative interventions. When operations on the upper abdominal region alone are considered, this figure rises to 10 per cent and higher. The mortality from the same cause is given as 0.6, or one in every 200 cases. The view that ether anesthesia, because of its chilling effect on the lung and the increased possibility for aspiration of septic contents from the mouth into the bronchial tree, was largely responsible, was abandoned when studies revealed that the introduction of local and spinal anesthesia did not diminish either the morbidity or the mortality from this cause.

Research on the pathogenesis of the postoperative pulmonary complications resulted in three distinct theories: that of aspiration pneumonitis developed by A. O. Whipple; that of infected emboli supported by Lichtenberg, Wölfler, Cutler and Morton, Cutler and Hunt, and others; and, more recently, that of pulmonary atelectasis. Since William Pasteur in 1910 revived interest in postoperative collapse of the lung, the number of reported cases has risen, so that in 1930 Coryllos<sup>1</sup> believed its incidence to be nearer 50 or 75 per cent.

The most striking clinical and roentgenologic sign of massive collapse of the lung is the unusually high position and immobility of the diaphragm. This led Pasteur and Sir John Rose Bradford to believe that the collapse was due to paralysis of the diaphragm and that this paralysis was a reflex phenomenon. Yandell Henderson<sup>2</sup> emphasized the fact that after an operative intervention there is a loss of tonus involving all of the body musculature. In the thorax this decrease of tonus of the respiratory muscles and particularly of the diaphragm results in such a diminution of the size of the thoracic cavity and such a deflation of the lungs that many minute deaerated areas are produced. He believes that this condition of hypoventilation exists in most cases after an abdominal operation. Churchill and McNeil<sup>3</sup> demonstrated a reduction of the vital capacity to 30 and 50 per cent of the normal in patients following an abdominal operation. Khromov<sup>4</sup> showed that a comparison of a regimen of protracted stay in bed after an abdominal operation with that of leaving bed early reveals that the vital capacity on the latter regimen is affected much less and returns to normal much more promptly. These authors likewise pointed out that there is a direct relationship between the reduction in the vital capacity and the incidence of pulmonary complications.

The second factor, one apparently of determining importance, is the accumulation of mucus in one or another bronchus. The air in the occluded lobe or lung is absorbed, and collapse of the alveoli follows. The clinical course of the massive collapse of the lung, with its almost invariably excellent prognosis, and above all the striking results of the bronchoscopic aspiration, emphasize the importance of the mechanical factor of the occlusion of a bronchus by a mucous plug. Lee, Tucker and Clerf<sup>5</sup> cured a case of postoperative collapse of the lung by bronchoscopic aspiration of the mucous exudate and produced a typical pulmonary collapse in an anesthetized dog by introducing into its right bronchus the material aspirated from the patient. Coryllos believes that postoperative bronchitis, atelectasis and pneumonitis have the same etiology. He bases his assertion on the clinical, pathologic and etiologic similarities of the three conditions and regards them as successive steps of essentially the same process. The two important factors in determining the collapse are the viscid and tenacious mucus in the bronchial tree and the impairment of the natural means of defense: namely, coughing, respiratory movements and ciliary action. The more or less temporary occlusion of a bronchus leads to the absorption of the alveolar gases of the collapsed lung. The

represented, according to announcements. Motion pictures will be used and in many cases the treatment of certain diseases will be demonstrated. The relation of physics and chemistry to medicine will be shown in exhibits, and possibilities of the future will be indicated in displays dealing with research.

## Government Services

### Dr. Thompson Appointed Director of Institute of Health

Dr. Lewis R. Thompson, assistant surgeon general, U. S. Public Health Service, has been made director of the National Institute of Health, effective February 1. Dr. Thompson is 53 years of age and a graduate of the Louisville Medical College, class of 1905. From 1932 to 1934 he was a scientific director of the International Health Division of the Rockefeller Foundation and is now in charge of the division of scientific research of the public health service. Dr. Walter T. Harrison, senior surgeon in the service, has been placed in charge of the division of biologic control of the institute.

### Annual Report of Public Health Service

According to the annual report of the surgeon general of the U. S. Public Health Service for the fiscal year ended June 30, 1936, the general death rate in twenty-five states was 10.8 per thousand of population as compared with 10.9 in 1934. The infant mortality rate, based on data from twenty-four states, was 52 deaths per thousand live births for the calendar year 1935, the lowest infant mortality rate recorded for these states. In twenty-four states the maternal mortality rate was 5.3 deaths of mothers per thousand live births. New low mortality rates were recorded for tuberculosis (54.3 per hundred thousand of population), diphtheria (3) and typhoid (2.8). Neither cholera nor yellow fever appeared in the United States during 1935. Three cases of plague occurred during the first six months of 1936, one in April in Sonoma County, Calif., one in June in Monterey County, Calif., and one in June in Beaver County, Utah. Plague infection was found in ground squirrels in California, Oregon, Montana and Idaho, and in fleas from ground squirrels taken in Nevada. After the close of the fiscal year, in July and August 1936, plague infection was found in a marmot, in ground squirrels and in prairie dogs from Utah. A fatal case of plague was reported in Hamakua District, Hawaii, in March 1935. During the calendar year 1935 twenty plague-infected rats were found on the island of Hawaii and six on the island of Maui, and during the first six months of 1936 eight plague-infected rats were found in Hawaii.

A total of 10,839 cases of poliomyelitis was reported in 1935 as compared with 7,517 cases for 1934 and an average of 8,249 cases for the five years ended with 1934. During 1935 the disease was unusually prevalent in North Carolina, Virginia, the District of Columbia and several of the Northeastern states. Although nearly 8,000 cases of smallpox were reported in the United States in 1935, an increase of more than 2,500 over the number for the preceding year, the prevalence was less than that for any year prior to 1933 for which there are records. The New England and Middle Atlantic states reported only three cases, while Montana and Wyoming together reported 1,060 cases. No cases were reported in Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New Jersey, Pennsylvania and the District of Columbia.

During the year 266,626 new cases of syphilis and 162,487 new cases of gonorrhea were reported to the state health departments as compared with earlier totals of 254,551 and 161,810 respectively; 713 clinics furnishing morbidity reports to state health departments reported 79,905 new cases of syphilis and 44,358 new cases of gonorrhea. They discharged as arrested or cured 63,566 patients and gave a total of 3,344,257 treatments, including 934,063 doses of arsphenamine.

There were examined 15,981 vessels, carrying 733,495 passengers and 1,182,232 seamen. Of a total of 3,823 airplanes, carrying 37,352 persons, which arrived at airports of entry in the United States from foreign countries requiring quarantine inspection, only 2,281 airplanes carrying 31,898 persons, of whom 5,537 were aliens, were inspected by medical officers prior to entry, owing to many arrivals at airports at which medical officers are not available. Fumigations were made of 1,193 vessels either for the destruction of rats or because of the presence on board of some contagious disease. Examinations for plague infection were made of 2,971 of the 4,585 rats

retrieved following fumigation. No importation of any of the quarantinable diseases into the United States or its possessions occurred during the fiscal year. One vessel arrived at Boston with a case of smallpox. Two cases of smallpox were detected on the Mexican border and refused entry.

Hospital and outpatient care was furnished to American seamen and other beneficiaries at 154 ports; 331,215 accredited persons applied for treatment and other medical service. There were 102,573 more hospital days furnished to all classes of patients during the fiscal year 1936 than in 1935. New hospital facilities were completed and occupied at Stapleton, N. Y. A new hospital ward building at Memphis is under construction and funds have been allocated for complete new hospitals at Boston and St. Louis.

The report points out that industrial diseases are becoming a chief consideration. In a study of about 7,000 workers employed in fourteen factories, about one third were examined for the existence of skin hazards. An investigation was made of the dust hazard incident to the asbestos textile industry in North Carolina. Of 517 persons examined, forty-six, or 8.9 per cent, had asbestosis. During the year establishment of industrial hygiene units in the health departments of industrial states was inaugurated with the passage of the Social Security Act. A seminar for thirty-four physicians and engineers from sixteen state health departments was held in May 1936 for the purpose of training personnel in the specialized field of industrial hygiene.

Studies on child health completed during the year revealed that, so far as size and growth of children are concerned, the depression has not seriously affected any considerable number of American children. Automobile accidents, burns, drowning, falls, poisonings and mechanical suffocation are the most frequent causes of accidental fatalities of children under 15 years of age.

The largest quantity of Rocky Mountain spotted fever vaccine yet produced, 506.8 liters, was prepared during the fiscal year. Sufficient vaccine to vaccinate the personnel in forty-eight camps in the more dangerous endemic areas of the West and Northwest was furnished to the Civilian Conservation Corps. The incidence of the disease showed a marked decrease.

Special studies were made on heart disease, with emphasis on rheumatic fever, the largest single cause of disability and death from heart disease, and surveys are now in progress in San Antonio, Texas, and in Mecklenburg County, N. C., to determine the prevalence of brucellosis, particularly in atypical and chronic forms. Of special importance was the study of serodiagnostic tests for syphilis, which included an evaluation of the ability of state, municipal and private laboratories to perform these tests.

For the first time in the history of the public health service, a national health program was made possible under the provisions of the Social Security Act. Grants-in-aid were made to the states for the last five months of the fiscal year 1936 and allocations were made for 1937. By the close of the period covered by this report, every state had submitted a program of work under the provisions of the public health title of the Social Security Act.

Since the opening of the U. S. narcotic farm at Lexington, Ky., in May 1935, 1,240 patients have been admitted. Of these 960 were admitted during the fiscal year 1936 and 479 were discharged, leaving 761 patients in the institution at the close of the year. Of the voluntary patients discharged as cured none are known to have relapsed, but some of those discharged as having received maximum benefit have relapsed as well as some of the prisoners released on "conditional release" and parole. Plans were inaugurated during the year to furnish psychiatric diagnostic services to federal courts for a period of one year as a research project to determine the feasibility of establishing such services as a permanent activity of the service. The first unit was established at Boston in May 1936, and similar units will be set up at other points throughout the country. The report emphasizes the need of a new dispensary at Washington, D. C., to replace the present inadequate facilities for relief activities; the completion and rehabilitation of the hospital plant at Fort Stanton, N. M., including the construction of a recreation building and quarters for doctors, nurses and attendants; replacement of all existing frame structures at the leper hospital, Carville, La., with fireproof construction; completion of the marine hospital at Stapleton to provide a total of 1,200 beds, and a building to house a cancer investigation laboratory, and the erection of new hospitals in Miami, Fla., Los Angeles and Portland, Maine. The appropriations during the fiscal year totaled \$15,939,712, including social security grants of \$3,333,000. A total of \$14,914,170 was expended by the service.

benefit their personal interests. The cult proposals fall into three classes: (1) to force governmental and tax-exempt hospitals to permit all practitioners of the healing art, no matter whether they are physicians or practitioners of bizarre cults, to practice within their confines; (2) to authorize osteopaths, chiropractors, naturopaths and other substandard practitioners to care for, at the employers' expense, workmen injured in the course of their employment; and (3) to force public officials, charged with the duty of furnishing medical care to indigents and other persons on relief rolls or unable to pay for such services, to permit cultists to treat such persons at public expense. Bills to force hospitals to admit cultists to practice in them are pending in twelve states. None of them have as yet been reported out of committee, but there is always the danger that one or more of them will be enacted. The threat which these bills offer certain hospitals is obvious. Proposals to permit cultists to render services in workmen's compensation cases are pending in Congress and in two states; similar proposals may be expected in other states before the present legislative sessions are ended. A law has been enacted in Oklahoma this year which in effect permits osteopaths to treat indigents at public expense. A proposal has passed the North Dakota house to permit licensed adherents of any cult to treat such cases, and a similar proposal has been killed in New Hampshire. The fate of bills of this type rests to a great extent on the presence or absence of vigorous opposition on the part of the medical profession and its members and on the ability of the medical profession to convince legislators of the dangers inherent in such bills. In view of the baneful effect on the public health which the enactment of such measures would have, it is the duty of the medical profession to oppose such legislative activities energetically. The public should certainly discourage such waste of their legislators' time.

#### "IS MILK CANCER'S ALLY?"

In an editorial a few weeks ago THE JOURNAL condemned the editors of *Esquire* and *Coronet* for printing articles in the medical field without scientific background. Their ignorance in accepting and publishing such articles as they have published on the glands and on autotherapy was a sort of unfortunate, supercilious or silly ignorance. Now in the March issue of *Coronet* they lead off with an article entitled "Is Milk Cancer's Ally?" that betrays such a broad and comprehensive ignorance of milk and of cancer that one is stimulated to wonder as to the mental age of both editors and author of this publication. Here is the old argument that modern civilized man died of cancer but the American Indian did not die of cancer. The answer is of course that modern civilized man has a life expectancy of some sixty years at birth whereas the life expectancy of the Indians was about thirty years at birth. The Indians simply did not live long enough to die of cancer. More than 90 per cent of deaths from cancer occur in persons over 40 years of age. The Indians died of infectious diseases, exposure and other Indians. The same argument has been made with relation to the eating of white bread versus the eating of whole grain. It

might just as well be made with relation to automobiles. The Indians had no automobiles; hence the Indians did not die of cancer. Some preposterous arguments are made to show that cancer rates are higher in the states using the most milk. It may easily be shown that life expectancy is longer in the states using most milk because of better nourishment in those states. In some small type at the end of its article *Coronet* affirms its seriousness in presenting this article; this affirmation adds insult to injury. There is evidence that the article has already produced fear in the minds of some readers who do not stop to remember that neither the author of the article nor the magazine that prints it has the slightest scientific standing.

### Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

Information concerning new medical legislation in various states appears in the Organization Section of The Journal.

#### ARKANSAS

**Dr. Vinsonhaler Retires as Dean.**—Dr. Frank Vinsonhaler, since 1927 dean and professor of medical ethics at the University of Arkansas School of Medicine, Little Rock, has announced his retirement. He will be succeeded by Dr. Silas C. Fulmer, professor of medicine and associate dean of the school. Dr. Vinsonhaler was born in Graham, Mo., in 1864 and graduated from Columbia College of Physicians and Surgeons, New York, in 1885. He was for many years professor of ophthalmology at Arkansas and engaged in private practice in Little Rock. He retired from practice in 1934 to devote full time to his duties at the medical school. He was president of the Arkansas Medical Society, 1900-1901, and in 1933 was awarded a medal by Columbia University for conspicuous service rendered to the university. Dr. Fulmer graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1922.

#### CALIFORNIA

**Special Meeting in Honor of Guests.**—The Los Angeles County Medical Association held its meeting January 25 in honor of the guests of the sixth annual midwinter clinical course, given by the Research Study Club of Los Angeles. The speakers were Drs. Edward Jackson, Denver, on "The Share of General Medicine in Preventing Blindness"; Felix R. Nager, Zurich, Switzerland, "The Mental Effect of Deafness," and Meyer Wiener, St. Louis, "Limitations in the Field of Ophthalmology for the Man in General Practice."

#### COLORADO

**Midwinter Graduate Clinics.**—The Colorado State Medical Society held its annual midwinter graduate clinics in Denver, January 21-23. Sessions were held at the Denver General, St. Joseph's, Children's, St. Luke's and Colorado Psychopathic hospitals, and the Cosmopolitan Hotel. The speakers included:

Dr. Arthur E. Hertzler, Halstead, Kan., Cardiotoxic Goiter.  
Drs. John C. Mendenhall and Thomas D. Cunningham, Treatment of Bronchial Asthma by Injection of Iodized Oil.  
Dr. Charles J. Lowen, Massive Collapse of the Lung.  
Dr. Harold R. McKeen, Gallbladder Disease in Relation to Cardiac Lesions.  
Dr. Paul R. Weeks, Radiation in Treatment of Malignancy of Head and Neck.

**Society News.**—At a meeting of the Mesa County Medical Society in Grand Junction, January 19, Dr. Galen M. Hover, Grand Junction, discussed the treatment of gonorrhea and Dr. Gordon G. Feldman, Grand Junction, the treatment of common skin diseases.—The Fremont County Medical Society was addressed in Florence, January 25, by Dr. Aurel Goodwin,

7.2.61 1.50

the position was increased by the tendency of juries to award high damages. He divided actions for negligence into four groups: 1. The purely malicious, in which allegations were made by a disgruntled patient on no substantial grounds, perhaps to avoid paying his bill. A summons by a defense society would often bring payment, sometimes immediately before the hearing. 2. Cases in which there had been negligence. Here the proper course was to obtain a settlement on the best possible terms at the earliest possible moment. 3. Cases in which there appeared to the layman to be evidence of negligence, but from the medical point of view there was quite a good defense. If the complainant was reasonable it might be wiser to make a settlement on suitable terms without allowing the matter to be pursued by legal process. Often the defense society was convinced that there was a perfectly good defense but the respondent was unwilling to go into court because of the undesirable publicity even if the verdict should be favorable. 4. Cases in which there had been negligence but the physician was not to blame. Until recently it was held by the law that the physician primarily in charge of the case was responsible for all that happened. Now he was regarded as responsible in his own field. The surgeon was responsible for seeing that the theater sister was properly trained, but he was not responsible for a mistake made by her.

## PARIS

Feb. 13, 1937.

### Insulin Treatment of Schizophrenia

The Nov. 23, 1936, meeting of the Société médico-psychologique of Paris was devoted to a symposium by visiting and local alienists on the insulin treatment of schizophrenia. Muller of Munsingen reported the experience in 300 cases in Vienna and Switzerland. There were only four deaths, and these were due to organic disease associated with the mental disorder. The results were grouped according to the duration of the disease: Group 1, disease of less than six months' duration: 89.8 per cent improved, including 73 per cent completely cured. Group 2, disease of more than six months' duration: 82 per cent improved, including 50 per cent completely cured. Group 3, disease of more than eighteen months' duration: 45 per cent improved but including only 0.5 per cent complete cures. The reactions that have been observed vary from somnolence to convulsions, salivation, coma and numerous neurologic symptoms (pyramidal, meningeal, reflex). The treatment is to be given for several weeks.

Schmid of Münchenbusec spoke on the histopathology of insulin shock. Eleven rabbits were given daily injections of insulin at the rate of 2 cc. per kilogram of body weight over a period of several weeks. The symptoms resembled in every respect the neurologic and organic signs of hypoglycemia. Immediate necropsy of animals killed (before death from hypoglycemia could take place) has revealed much less marked changes in the nerve centers than anticipated. No destructive lesions, hemorrhage or edema were found, only "tumefaction." The changes were those of a capillary hyperemia due to the epinephrine response to the insulin treatment.

Bersot of Neuchâtel described the neurologic syndrome of insulin shock. Following injection the patient, before becoming more or less deeply comatose, can present all sorts of cortical, pyramidal, extrapyramidal and vagosympathetic symptoms. One most commonly observes tonic rigidity, clonic twitchings, more or less uncoordinated movements of the face and trunk, catatonic attitudes, stereotyped gestures, attacks of convulsive epilepsy, abolition of one or all reflexes, excessive perspiration and salivation, vasomotor disturbances, and a bradycardia down to 50. An instructive film was shown, illustrating the neurologic symptoms of insulin shock.

Guirard and Nodet read a paper on the principles and technique of insulin treatment. It is impossible to prove the theories as to the mechanism of this method. Experience has shown that severe physical ailments are often followed by the most chronic mental diseases. This suffices as a basis for cautiously reproducing severe organic disturbances in certain psychiatric cases, incurable by other methods, in order to improve the mental condition. The patient thus treated must be under the constant surveillance of the physician or intern, who has dextrose solutions ready to administer in case the symptoms following insulin injection should threaten life. The temperature should be taken frequently so as to detect an excessive lowering (hypothermia). The respiration must also be carefully noted and apparatus for artificial breathing be close at hand in case of necessity. The doses of insulin that produce coma should be kept at a minimum and not progressively increased, because the susceptibility of patients varies greatly. Carbohydrates should not be given the day before insulin is injected, and only a small dose of the latter, given every two days. If these precautions are followed, the chances of success are greatly increased.

Claude and Rubenovitch took up the insulin shock treatment of schizophrenia. Professor Claude is the leading alienist in Paris, having a large service at the St. Anne Asylum. They stated that the insulin should be injected early in the morning before breakfast. The effects last for three hours. The injections are given daily for five days, followed by an interval of two days. The sensibility of every patient is evidenced by the difference in time of appearance of the symptoms of shock. The insulin shock causes an "anarchic" activity of the somatic, neurovegetative and psychic functions. The coma should never be prolonged. It should be allowed to recede slowly and progressively in making use of psychotherapy during the recession period. The results obtained by using insulin as a shock treatment prove that the neurologic disturbances are due to a dynamic dysfunction and not to a lesion.

Bauer of Naugeat stated that his observations in seventeen cases have convinced him that the favorable results in schizophrenia are beyond dispute even in cases of long duration. The dangers of the treatment can be minimized through vigilant surveillance. During the recession of the coma, one has an excellent opportunity to study the psychologic mechanism of the disease.

### Congress of French Electroradiologists

The third annual Congress of French Electroradiologists was held in Paris, Oct. 8-10, 1936. The first paper, on radiologic features of osteo-articular disturbances termed chronic rheumatism, was read by Robert and Forestier, who divided the bone changes into two groups: (a) arthritis, or infectious lesions, and (b) arthroses, or degenerative lesions. The former are characterized by local and general decalcification of the bone, by ulceration of the bone contours and, from the point of view of evolution, by the possibility of arrest of development of the lesions or even by reconstructive articular changes. The arthroses, on the other hand, are characterized by the production of erosive lesions at areas where there is articular friction, by the formation of osteophytes and by the slow, progressive character of the evolution of the lesions. A special place ought to be given to inflammatory disorders, which determine calcification of ligaments, the early diagnosis of which is of much importance in such a serious disease.

Three papers on high voltage radiotherapy formed a symposium on this subject. One on the physical aspects was read by Wangermez and Aurioc of Bordeaux. A primary well founded fact at present is that of the nonelectivity of short wavelengths. Based on the general principles of physics, it appears that radiant energy can be utilized only by a diminution of frequency and formation in the tissues of radiations of

**Society News.**—The Baltimore City Medical Society was addressed January 8 by Drs. Walter L. Winkenwerder and Leslie N. Gay, "Clinical Course and Treatment of Allergic Rhinitis"; Lawrence R. Wharton, "Criteria of Cure in Gonorrhea in Women," and James C. Owings and Otto C. Brantigan, "Intraspinal Injection of Absolute Alcohol for the Cure of Intractable Pain."—At a meeting of the Historical Society of the University of Maryland, January 19, Drs. George Carroll Lockard and James M. H. Rowland, Baltimore, discussed "Medicine in Baltimore in the Early Part of the Nineteenth Century and the Organization of the University of Maryland."—Dr. Joseph E. Moore, Baltimore, addressed the Frederick County Medical Society, recently, on "The Control of Syphilis in Maryland."

#### MASSACHUSETTS

**New Health Commissioner for Boston.**—Dr. Henry F. R. Watts, Dorchester, has been appointed health commissioner of Boston, succeeding the late Dr. William B. Keeler. Dr. Watts graduated from Harvard University Medical School in 1894. He is 67 years of age. According to the *New England Journal of Medicine*, Dr. Watts has been a member of the health department since 1909 and for many years was a member of the faculty of Tufts College Medical School.

**Lowell Institute Lectures.**—Dr. Lewis W. Hackett, assistant director of the International Health Division, Rockefeller Foundation, and representative of the Rockefeller Foundation in Italy and Albania, is giving the current series of free public lectures sponsored by the Lowell Institute, Boston, in Huntington Hall. The series deals with "Man Against Malaria in Southern Europe" and the individual titles are "The World War and Malaria," "The Malaria Puzzle in Europe," "The Solution of the Problem," "Modern Strategy in Malaria Control," "The Albanian Experiments" and "Land Reclamation in Italy." The lectures opened February 2 and are being given Tuesdays and Fridays.

#### MICHIGAN

**Superintendent Appointed.**—Dr. Donald M. Morrill, director of Blodgett Memorial Hospital, Grand Rapids, has been appointed medical superintendent of the Receiving Hospital, Detroit. He assumed the position March 1. In a recent competitive examination for the position, Dr. Morrill received a rating of 96, the highest in the group. He graduated from the University of Michigan Medical School, Ann Arbor, in 1918. He served as chief resident at the University Hospital and later as assistant superintendent.

**Society News.**—Dr. George W. Crile, Cleveland, addressed the Detroit Philosophical Society, February 19, on "The Interpretation of Man."—At a meeting of the Essex County Medical Society in Windsor, February 2, Dr. Frank A. Kelly, Detroit, spoke on "Hernia, with Special Reference to Injection Treatment."—Dr. William S. Reveno addressed the staff of Highland Park General Hospital and the Highland Park Physicians' Club, February 4, on "Medical Management of Hyperthyroidism."—At a meeting of the Macomb County Medical Society, January 18, Dr. Bernhard Friedlaender, Detroit, discussed "Chronic Endocervicitis, Its Significance and Rational Treatment."—At a meeting of the Muskegon County Medical Society in Muskegon, February 26, Dr. William R. Cubbins, Chicago, spoke on "Abdominal Injuries."—The Detroit Pediatric Society was addressed February 3 by Dr. Herman L. Kretschmer, Chicago, on "Surgical Lesions of the Genito-Urinary Tract in Infancy and Childhood."—Dr. Frederick J. Taussig, St. Louis, addressed the Wayne County Medical Society, Detroit, March 1, on "The Legal and Social Control of Induced Abortion." Dr. Ambrose L. Lockwood, Toronto, addressed the surgical section of the society, February 22, on "The Surgical Dyspepsias."

#### MINNESOTA

**Dr. Maxcy Appointed a Scientific Director.**—Dr. Kenneth F. Maxcy, professor and head of the department of preventive medicine and public health, University of Minnesota School of Medicine, Minneapolis, has been selected as one of the scientific directors of the International Health Division of the Rockefeller Foundation. The appointment, effective January 1, is for three years. Dr. Maxcy graduated from Johns Hopkins University School of Medicine in 1915 and represented the U. S. Public Health Service at the malaria conference of the League of Nations in Geneva in 1928. Prior to his appointment at Minnesota, Dr. Maxcy was professor of preventive medicine and bacteriology at the University of Virginia School of Medicine, Charlottesville.

#### MISSOURI

**Centennial Celebration Postponed.**—The St. Louis Medical Society will celebrate its one hundredth anniversary April 5-7 instead of March 22-23 as previously announced. The program will include a reenactment of the first meeting, portrayed from the original minutes in the archives of the society and written by Dr. Arthur W. Proetz, an account of the society's history by Dr. James Archer O'Reilly, and a discussion of the "Aims and Accomplishments of Medical Societies and Ours in Particular" by Dr. Malvern B. Clopton. Tuesday evening the speakers will be Drs. Major G. Seelig on "Medical Progress in the Last One Hundred Years" and Amand N. Ravold, "Our Library." The woman's auxiliary will present a play by Byron B. Boyd entitled "Mushrooms Coming Up." Dr. R. Emmet Kane will be toastmaster at the dinner Wednesday evening in the Gold Room of the Jefferson Hotel, and the speakers will include Dr. Robert E. Schlueter on "The Art of Medicine"; Rev. Martin O'Malley, D.D., "The Great Physician," and Charles M. Hay, LL.D., "The Doctor and the State." Memorabilia of the society will be on exhibition during the centennial.

#### NEW YORK

##### Theobald Smith Memorial Laboratory to Be Dedicated.

—A new laboratory for the departments of physiology, pharmacology and experimental surgery at Albany Medical College, Union University, Albany, will be dedicated March 19 to the memory of the late Dr. Theobald Smith, who was an alumnus of the college. Dr. Thomas Ordway, dean at Albany, will give the principal address at an afternoon ceremony, at which a plaque of Dr. Smith will be unveiled. At an evening assembly Dr. Charles R. Stockard, professor of anatomy, Cornell University Medical College, New York, will deliver an address on "The Spirit of the Laboratory." The new laboratory was remodeled from the old Albany County Hospital, according to a newspaper account. Dr. Smith, who has always been regarded as the "outstanding alumnus of the school," was a native of Albany and graduated from the medical college in 1883. He wrote a noteworthy thesis there on "Cell Activity in Health and Disease" and received a prize for obtaining the highest grade in the final examinations, says an announcement. Through his long career as professor of comparative pathology at Harvard University Medical School and head of the division of animal pathology at the Rockefeller Institute for Medical Research, Dr. Smith remained in touch with Albany Medical College and was twice president of the alumni association. He died Dec. 10, 1934.

##### New York City

**Personal.**—Dr. Robert P. Ball, Chattanooga, Tenn., has been appointed assistant professor of radiology at Columbia University College of Physicians and Surgeons.—Dr. Alan Gregg, New York, of the Rockefeller Foundation, addressed the Listerian Society at King's College Hospital, London, February 10, on research in psychology.

**Harvey Lectures.**—Dr. Thorvald Madsen, director of the Serum Institute, Copenhagen, Denmark, delivered the fifth Harvey Lecture of the current series at the New York Academy of Medicine, February 18. His subject was "The Scientific Work of the Health Organization of the League of Nations." Dr. Herbert S. Gasser, director of the Rockefeller Institute for Medical Research, will deliver the sixth lecture March 18 on "The Control of Excitation in the Nervous System."

**Dr. Curran Appointed Dean at Long Island.**—Dr. Jean A. Curran, who has recently made a survey of hospital internships and residencies in New York, has been appointed dean of Long Island College of Medicine, Brooklyn. Dr. Curran fills the vacancy created by the death of Adam M. Miller, M.A., who was dean from 1922 to his death in 1935. Dr. Wade W. Oliver, professor of bacteriology, has been acting dean. Dr. Curran was graduated from Harvard University Medical School, Boston, in 1921 and after a two year internship at Brooklyn Hospital spent six years in China. He returned to the United States seven years ago and for some time taught at New York University College of Medicine. Since 1934 Dr. Curran has been engaged in the hospital survey under the auspices of a special committee representing the New York Academy of Medicine and the five medical schools in New York, the final report of which is in process of completion.

**Society News.**—Drs. Thomas Grier Miller, Philadelphia, and Edward C. Reifenshtein, Syracuse, addressed the National Society for the Advancement of Gastro-Enterology, January 26, on "Factors in the Maintenance of Physiologic Conditions Within the Small Intestine" and "Lymphosarcoma of the Gastro-Intestinal Tract" respectively.—Drs. Bernard Glueck,

the women, a circumstance which goes far to explain why 59 per cent of the men (366 out of 616) and 82 per cent of the women (409 out of 496) had never before, or only at a late date, received any treatment. Only 20 per cent of the men and a mere 6 per cent of the women had received treatment directly after the infection. Of the patients who had received previous treatment (if these are considered separately) only 50 per cent of the men and 35 per cent of the women had been treated immediately following infection. Moreover, exactly one half of this previously treated group had received but a single treatment, which, of course, could not have sufficed to eradicate the disease.

The influence of syphilis on the patient mortality was considerable; among nonsyphilitic patients received during the five year period the death rate was 9.6 per cent, whereas that of the syphilitic patients was 15.7 per cent, that is, 61 per cent greater.

The incidence of incipient disturbances of the central nervous system and of the circulation was a particular object of study (from this category were excluded all cases of fully developed tabes, cerebrospinal syphilis and dementia paralytica). Among the syphilitic patients there were 151 persons, or 13 per cent of the total number, who presented incipient neural disorders. Pupillary alterations of various sorts were observed in 110 cases, and anomalies of the patellar reflexes in only fifteen. To these 151 wholly incipient cases were added 229 cases of fully developed neurosyphilis; this means that about a third of all the syphilitic patients presented a disturbance of the nervous system. In 16 per cent of all syphilitic patients there was pronounced tabes. Thus every sixth syphilitic patient was tabetic. Careful evaluation of the connection between metasyphilis and therapeutic measures showed that there exists no provocation of tabes with antisyphilitic treatment at least, if only the antisyphilitic therapy is initiated as early as possible and administered intensively and repeatedly. The age of the male tabetic patients ranged from 25 to 66 years (the 25 year old tabetic patient became ill six years after infection; the 66 year old patient, twenty-seven years after infection). The average period of incubation was fourteen years (on the basis of forty-seven cases). The mean age of male tabetic patients at the time of first manifestation of the disorder was about 44 years; the mean age at which the disease had attained its complete clinical form was above 50 years. It may be that this six year interval should be regarded as the mean duration of development of tabes from the incipient stage to the stage of fullest development. The mean age of the tabetic women lay somewhat below that of the men; for the women too the average period of incubation amounted to fourteen years. The Wassermann reactions were positive for only about half of the tabetic patients, for 65 per cent of the women and for 50 per cent of the men. Accordingly, positive Wassermann reactions were even less frequent among the tabetic patients than among the syphilitic patients taken as a whole, perhaps because of the more intensive treatment usually accorded tabetic patients in the course of their illness.

With regard to syphilis of the circulatory system, thirty-one of the 155 tabetic patients (one in every five) presented unequivocal syphilitic disease of the aorta. On the other hand, aortic disease was established in only 137 of the 1,112 syphilitic cases; namely, one out of every nine patients was so afflicted. Of the 175 syphilitic patients who died in the course of the five year period, sixty-three patients (one out of every three) presented disease of the aorta accompanied in some instances by aneurysms and diseased valves. In twenty-two cases, that is, one out of every eight cases, there was a postmortem finding of coronary sclerosis. Syphilitic disease of the aorta or coronary arteries was given as the cause of death in thirty-seven of the 175 fatal cases. Vascular disease thus accounted for a fifth of the fatalities among syphilitic patients. Clinically, most of

these thirty-seven fatal cases presented a picture of chronic cardiac insufficiency; not infrequently, however, there were sudden cardiac failures due in a few instances to the rupture of an aneurysm.

### Congress of the German Society of Pathology

At the 1936 congress of the German Society of Pathology, held in Breslau, Professor Fischer-Wasels presided, and the chief topic of discussion was "Spontaneous Cerebral Hemorrhages." Nordmann of Hanover supplemented his observations with abundant illustrations. In two cases in which arteriography was used, permanent cerebral stasis with subsequent malacia was demonstrated. It was possible in cases of traumatic carotid sinus thrombosis to gage the progressive stages of this process: permanent stasis, diapedesis, malacia, vascular necrosis. In arteriosclerosis, cyclic hemorrhage and necrosis of the media were considered as characteristic prehemorrhagic alterations. If a malacia relates to the capillaries and is surrounded by cyclic hemorrhages, the afferent arteries will frequently exhibit necroses on the basis of which hemorrhages originate. The frequently encountered necrosis of the media in arteriosclerotic patients leads, after partial rupture of the arterial walls, to the formation of mural hematomas and of aneurysms. It has been proved by statistics that in hypertonic patients the softening process is manifested on an average ten years subsequent to the massive hemorrhage. In experiments it was determined that the "hypertensive" animals are especially predisposed to local disturbance of the cerebral circulation.

Professor Westphal of Hanover accords a prominent place in the production of spontaneous hemorrhage to the vascular functional factors. Necroses of the arterial walls, all important in the etiology of massive hemorrhages, are in turn based on functional ischemias. Changes in the vasomotor functions within the brain can first of all be determined on the basis of alterations in the fundus oculi. Westphal further considers an increase in the lactic acid a prime etiologic factor in arterial necrosis.

Beitzke of Graz discussed the rôle of small aneurysms in massive hemorrhage of the brain. In fifteen cases observed by him, small aneurysms were found concomitant with badly diseased arterial walls. Moreover, from microscopic observations in the brain substance he assumes the following etiologic background for the hemorrhage: After the bursting of an aneurysm the blood burrows into the cerebral substance which has been altered by atrophy or scarification and, proceeding farther, breaks the tissue asunder. By the rupture of a small adjacent vessel a fatal hemorrhage can be produced within the space of a few minutes.

After comparative studies of apoplexy and malacia, Fahr of Hamburg decided that younger persons are affected by apoplexy more frequently than is commonly assumed. The tendency of miliary aneurysms to form in apoplectic states has also been distinctly undervalued. In the majority of apoplexy cases the hemorrhage was traceable to organic alterations of the blood vessels; in a few cases, however, spasms seemed a more likely cause.

Among the papers submitted, Roessle of Berlin discussed the internal or anatomic similarity of blood relatives. In enzygotic twins there exist, in addition to external resemblance, striking visceral similarities; in one case these involved the contour of the heart, anomalies of the cardiac apex, the shape of the liver and distinctive furrows and flaps in both the liver and the lungs. Two of a set of triplets were considered to be enzygotic twins. This pair exhibited extensive correspondences in the shape of the heart, including the apex, whereas the third triplet presented a differently shaped heart.

Aschoff of Freiburg-in-Breisgau, on the basis of 150 cases, studied the types of pneumococci present in various organic diseases. In lobar pneumonia types I, II and III preponderated

## WYOMING

**Maternal and Child Health Program.**—The state board of health at its annual meeting in Cheyenne January 17 adopted a program for the new division of maternal and child health set up under the Social Security Act. The plan was drawn up by an advisory committee appointed by the governor, of which Dr. Josef F. Replogle, Lander, president of the Wyoming State Medical Society, was a member. Education is the keynote of the program, education of the lay public by classes, lectures and special literature and education of the medical profession by institutes and refresher courses in obstetrics and pediatrics. There will also be an investigation of maternal deaths, infant mortality and the physical status of children in general. Finally, public health nurses will be assigned to counties that desire them to educate the community in health matters. These nurses are instructed to work under physicians' orders when sick persons have a family doctor. They are expressly instructed not to suggest or show preference for any physician. Material to be used in classes for expectant mothers will be submitted to the family physician before classes are formed. Dr. Margaret H. Jones, Cheyenne, is director of the new division.

## ALASKA

**Tuberculosis Clinic.**—St. Ann's Hospital, Juneau, recently opened a weekly tuberculosis clinic under the auspices of the territorial board of health. The same service is provided to natives at the government hospital on other afternoons weekly. According to the *Bulletin of the National Tuberculosis Association*, the incidence of tuberculosis in the territory of Alaska is now four times as great as that in New York.

## PHILIPPINE ISLANDS

**Medical Election.**—At the recent annual meeting of the Philippine Islands Medical Association in Cebu, Dr. Juan C. Nanagas, Manila, was elected president and Dr. Antonio S. Fernando, Manila, was reelected secretary. Drs. Ramon L. Blanco, Cebu, and Sixto A. Francisco, Manila, were made vice presidents.

## GENERAL

**Academy of Ophthalmology and Otolaryngology.**—The annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Chicago at the Palmer House, October 10-15, instead of Detroit, as first decided. The society plans to make its scientific exhibit this year definitely educational, as well as to permit members on the program to demonstrate, through exhibits, material supplementing their contributions. Members having such exhibits are asked to communicate as soon as possible with Dr. William P. Wherry, executive secretary of the academy, 107 South Seventeenth Street, Omaha, Neb.

**Warning Against Fraudulent Salesman.**—A man giving the name J. S. Ray is reported to have solicited orders for a medical dictionary, magazines and "National Medical Monographs," a six volume work, as a representative of the Continental Press, Inc., 418 Wabash Avenue, Chicago. The National Publishers' Association recently issued a bulletin warning against a man using this scheme in the Southern states. He uses a fake contract form and a fake receipt. There is no such concern as the Continental Press, the bulletin says. Any one approached by this man is asked to hold him if possible and wire immediately to Mr. Frank Ware, National Publishers' Association, 232 Madison Avenue, New York.

**Conference on Silicosis.**—The division of labor standards, U. S. Department of Labor, sponsored its second conference on silicosis in Washington, D. C., February 3. Committees appointed by Secretary Perkins following the first conference in April 1936 made their reports. The speakers included Verne A. Zimmer, director, division of labor standards, and Secretary Perkins. Chairmen of the committees are:

Dr. Royd R. Sayers, U. S. Public Health Service, Washington, Committee on Prevention of Silicosis Through Medical Control.  
Warren A. Cook, Hartford, Conn., Committee on Prevention of Silicosis Through Engineering Control.  
V. P. Ahearn, Washington, Committee on Economic, Legal and Insurance Phases of the Silicosis Problem.  
L. Metcalf Walling, Providence, R. I., Committee on the Regulatory and Administrative Phases of the Silicosis Problem.

The first silicosis conference was called by Secretary Perkins following reports to Congress that silicosis had caused the deaths of "many workers" on a tunnel project in West Virginia.

**Opportunities for Physicians in California.**—Examinations for the following positions in the California state service will be held March 27: physician and psychiatrist, physician

and surgeon, physician and internist and junior physician. The last is primarily for younger men and pays a salary of \$100 plus maintenance, while the others pay \$200 monthly plus living costs for each physician and his family. All four positions require a license to practice medicine in California and an education equivalent to that represented by graduation from an approved medical school. The "physician and psychiatrist" is also required to have had three years of experience in medical practice with some experience in psychiatry; the "physician and surgeon," three years of experience in medical practice with specialization in surgery, and the "physician and internist," three years of experience in medical practice with specialization in internal medicine, including one year of experience in an institution for the mentally diseased or deficient. The position of "junior physician" requires only one year of experience as a senior intern in a mental hospital or two years of experience as a junior intern, or two years of experience in the practice of medicine in a general hospital. Applications must be filed with the state personnel board in Sacramento before March 20. Physicians who are not residents of California will be eligible to apply for the positions.

**Foundation to Educate Needy Boys.**—A charitable foundation will be created under the will of the late Charles Hayden, New York banker, to assist needy boys and young men. According to the *New York Times* the bulk of Mr. Hayden's estate, estimated at about \$50,000,000, will be used to set up and endow the Charles Hayden Foundation. The general scope of the organization will be as follows:

1. To assist needy boys and young men.
2. To aid and assist in charitable and public educational uses and purposes for the moral, mental, intellectual and physical well-being, uplifting, upbuilding and development of boys and young men of this country.
3. To found and/or to provide scholarships for deserving boys and young men of this country and for graduates or undergraduates of colleges, and to assist them in attending any educational institution in this country or abroad.
4. To assist in and/or to found, equip or provide for the maintenance of institutions or associations for the advancement of learning in this country.
5. To aid, assist, build, equip and maintain clubs, gymnasiums and recreation centers in this country for the training and development of boys and young men.
6. To aid and assist and to receive, hold, administer and dispose of property to or for the benefit of any university, college, school or other institution for the advancement of learning or of any branch or department thereof or for the benefit of any hospital or of any branch or department thereof.

The will pointed out that in the disposition of the funds preference should be given to New York and Boston but emphasized that nothing in the will should be construed to prevent the aiding of such activities anywhere else in this country.

## CANADA

**Dr. Abbott Honored.**—McGill University, Montreal, at a special convocation conferred the honorary degree of doctor of laws, honoris causa, on Dr. Maude E. S. Abbott, formerly assistant professor of medicine and curator of the Museum of the History of Medicine. Dr. Abbott retired in August 1936 from the faculty of medicine after an association of thirty-seven years. She was graduated in 1894 from the University of Bishop College Faculty of Medicine, later absorbed by McGill, and was appointed assistant curator of the museum in 1901 and curator in 1902. She spent two years, 1923-1925, as professor of pathology and bacteriology at the Woman's Medical College of Pennsylvania, Philadelphia, after which she received the teaching appointment at McGill. Dr. Abbott has for many years been engaged in research on congenital heart disease.

## FOREIGN

**British Medical Journal Adopts New Cover and Type.**—With the first issue for January 1937 the *British Medical Journal* appeared with a new dress and with new and improved typography. The new type is far more readable than that formerly used and is arranged in a column with sufficient spacing and white space to aid greatly the eyes of those who peruse regularly this publication. Typographical improvement has also been made in the supplement to the *British Medical Journal*, which, like the Organization Section of *THE JOURNAL*, is concerned with problems of organizational and medical economic character.

**Medicine at the Paris Exposition.**—Three pavilions will be devoted to medicine at the Exposition of Arts and Technics that will open in Paris in May. One will be known as the Claude Bernard Pavilion, in honor of the great physiologist, and in it will be demonstrations of the functioning of the human body, including a "transparent man." In the Laënnec Pavilion will be exhibits showing the evolution of clinical medicine during the past fifty years. All branches of medicine will be

executives of those bureaus which deal with problems of public health, hygiene and sanitation would appear the surest and simplest means of fostering unity of action in the domain of hygiene and of arriving at a perfect synergy of the various organized groups without upsetting the administrative framework. The proposed innovation by no means implies the subordination of other departments to the ministry of health, it merely creates obligatory liaisons. The maintenance of tight partitions only acts as a detriment to concerted action.

The foregoing was the gist of the report submitted to the king which led up to the creation by his majesty of an inter-ministerial executive committee of sanitary affairs. The duties of this committee are to establish a liaison between the various bureaus that are concerned in any manner whatever with problems of health, hygiene and public sanitation and to coordinate the health activities sponsored by these bureaus. Any contemplated legislation, decision or regulation having to do with problems of health must be examined beforehand by the committee, and it is compelled to submit its report within two weeks after it has been provided with the material requisite for a study of the measure in question.

The chairman of the committee is the minister of public health or his representative. The committee is composed of fifteen members, fourteen of whom are selected by the various ministers to represent respectively the following governmental departments: public health, justice, foreign affairs and foreign commerce, the interior, public instruction, finance, agriculture, public works and unemployment reabsorption, social service and welfare work, economics, transportation; posts, telegraphs and telephones; national defense, the colonies. The fifteenth committeeman serves as secretary.

#### National Congress of Industrial Medicine

The twelfth National Congress of Industrial Medicine took place recently at Naples under the presidency of Prof. Nicolo Castellino. Respect was paid to the memory of Prof. Luigi Devoto, recently deceased, founder of the first clinic for the treatment of industrial diseases and the president of the Società di Medicina del Lavoro. The first official topic concerned pathology from modern industrial chemistry. Professor Castellino said that physicians have to be familiar with the reactions to substances used in industry to prevent and treat the pathologic conditions that may result from intoxications or other forms of contact of workers with industrial substances. The development of modern working methods may result in physical and psychic disturbances of workers, which may be as serious as those caused by contact of the organism with chemical substances.

The subject of the second topic was ear diseases from noise. Professors Bruzzi of Naples and Malan of Turin were speakers. Ear diseases from noises are of great importance in industrial medicine, as they may develop in several modern industrial fields. Noise is the stimulation of the hearing apparatus by periodic and nonperiodic vibrations in association, causing, respectively, specific and nonspecific sensations in the human hearing apparatus. The latter collects the sounds induced by from 16,000 to 20,000 Hertz waves. Infrasounds (lower than 16,000 Hertz waves) and ultrasounds (beyond 20,000 Hertz waves) stimulate the hearing apparatus with nonspecific sensations and may produce alterations. The most harmful effects from stimulation of the zone of maximal sensitivity of the human hearing apparatus are those produced by intense sounds of 23,000 Hertz waves. Trauma from noise may be acute or chronic. The slow and benign evolution of industrial deafness, the absence of lesions of the middle ear and of symptoms from

the vestibule, heredity and constitutional and endocrine predisposition of the worker are all factors in making a diagnosis. The speakers described the forms of deafness that develop in tinkers, weavers, railroad men, aviators and artillerymen. Early development of progressive lesions and failure of the treatment in improving the patient's condition are common characteristics of industrial deafness.

The third topic was diseases of the spine from work. Prof. Luigi Preti of Milan spoke on the causation of the condition. A process of degeneration of the intervertebral disks which is stimulated by continuous flexion, extension and bending of the spine during work is the most important factor. Degeneration of the vertebral disks is followed by a process of irritation of the periosteum of the entire vertebra, with possible consequent ossification of the periosteum and final destruction of the involved vertebra. Professor Prisco of Naples classified industrial spinal diseases in four groups: Those developed from repeated abnormal movements or effort of the spine, vertebral arthritis and diseases which seem to be related to infections that take place during work or with industrial intoxications. Diseases of the first group develop from para-industrial defective conditions of the worker stimulated by conditions of work beyond his individual resistance. Spondylitis deformans and apophyseal arthritis are the most frequent forms of vertebral arthritis in workers. They are the result of kinetic efforts which are necessary in performing certain types of work and have to be considered industrial diseases, especially from the point of view of medical insurance.

Professor Caso of Naples said that the dynamic, mechanical and physical agents which most frequently cause spinal diseases during accidents in work are acute effort, violence, falls, contusions, wounds and shock from either atmospheric or industrial electricity.

The fourth topic, obligatory insurance of workers against industrial diseases, was discussed by Professor Ranelletti of Rome. For the last two years, insurance against poisoning from lead, mercury, white phosphorus, carbon sulfide and benzene has been obligatory in Italy. Also insurance against ancylostomiasis is obligatory. The speaker reviewed statistical data obtained in Italy for the last two years in relation to frequency of denunciation, harm caused to workers from different diseases and the amount of money paid for indemnification and compared the data with those obtained in other countries. He advised that industrial medicine be more thoroughly taught in Italian universities.

Professor Aiello of Milan discussed the last topic, which was the mutual type of health insurance, a type of social insurance which is developing at the present in the departments of the ministry of working corporations in Italy.

The next Congress of Industrial Medicine will take place at Bari city.

#### Oncogenic Action of Hydrocarbons

Prof. Vincenzo Bisceglie of the Catania University, in a lecture recently given to the Società medico-chirurgica of the city, reported results of studies on the oncogenic action of polycyclic hydrocarbons. The author succeeded in obtaining growth of sarcomatous tumors from subcutaneous injections of 1:2 benzopyrene dissolved in olive oil in all rats that were treated. The tumors grew rapidly, passed by a process of infiltration and sometimes produced metastases. The speaker succeeded also in transplanting the tumors up to the fourth transplantation. Application of 1:2 benzopyrene over the skin of mice results in the production of spinocellular carcinoma in 75 per cent of the animals treated. The tumors develop within 110 and 162 days from the beginning of the treatment. Death took place shortly after development of the tumors. Lesions of the internal organs, especially myeloid transformation of the liver and the spleen and increase of the number of splenic megakaryocytes, were shown in all animals regard-

#### Regulations for the Health and Safety of Factory Workers

The present law regulating the conditions of work in factories is based mainly on the factory and workshops act of 1901, which has been amended from time to time but has never been subject to a general overhauling. Since 1901 there have been great advances in knowledge and practice with regard to health and safety in industry. The government is therefore about to introduce a new bill, which is not only consolidating but revising and is said to give greatly improved provisions. The requirements as to the cleanliness of factories are made more precise by including specific provisions with regard to accumulations of dirt and the cleaning of floors. The amount of space required per person is increased from 250 to 400 cubic feet, subject to a clause allowing the present arrangements to continue in existing workrooms, provided there is effective mechanical ventilation. In addition to requiring a reasonable temperature to be maintained in all workrooms, a standard of temperature is laid down for light work of a sedentary character, and power is given to the government to prescribe standards of temperature and prohibit unsuitable methods of heating. Not only must sufficient and suitable lighting be provided, but arrangements must be made for the medical supervision of the workers in certain circumstances, as, for example, in outbreaks of disease in particular factories.

#### SAFETY PROVISIONS

The provisions of the existing law have been largely recast and there are many new proposals requiring the adoption of various safety devices or arrangements, imposing duties on manufacturers with regard to the construction of new machines, and requiring precautions in the case of cranes, chains, air receivers and containers, compressed air receivers, and processes involving risk of explosion from dust or fumes. Specific requirements are laid down with regard to hoists and elevators, bringing them into conformity with modern practice. Provisions as to the means of escape from fire are considerably extended. When more than twenty persons are employed in the same building or when explosive or highly inflammable materials are stored or used, effective provision must be made for giving warning in case of fire. In certain cases effective steps must be taken to familiarize all employees with the means of escape and the routine to be followed in case of fire.

#### WELFARE WORK

By an act of 1916 the government was empowered to make "welfare orders" for work in factories. As the result of experience gained, specific provisions are now made for dealing with the provision of drinking water, washing facilities, accommodation for clothing in certain prescribed processes, and facilities for sitting for female workers. Existing provisions for the removal of dust are made much stronger. New provisions are introduced to control underground workrooms. Young persons must not be employed in lifting heavy weights, and maximum weights are prescribed both for them and for men and women, either generally or in particular industries.

#### SHORTER WORKING HOURS

According to the existing provisions, women and young persons may work in any week up to a maximum of sixty hours in nontextile and fifty-five and one-half hours in textile factories, exclusive of intervals for meals. Also women may be employed on a limited amount of overtime in certain trades. The bill greatly reduces hours. The weekly working hours shall not

exceed forty-eight and the daily nine, exclusive of intervals for meals. But to enable pressure of work to be dealt with, women and persons over the age of 16 may work overtime to an aggregate not exceeding 100 hours in the year, subject to a maximum of six in any one week and to overtime taking place in not more than thirty weeks in the year. Also the 100 hours may be increased to 150, by permission of the government, for women in trades subject to seasonal or other pressure. Persons under 16 are not allowed to work overtime, and provision is made for reducing the amount of overtime for persons over 16 in any process in which this is prejudicial to health. Exceptions are made for processes connected with the curing of fish, the preserving and canning of fruits and vegetables, and the making of cream, butter and cheese.

#### Store Depots for Gas Masks

The government is manufacturing 30,000,000 masks, enough to supply every person in the country in case of gas attacks. In the meantime the masks will be stored by the government, as they are of delicate construction and, if issued to the population now, many would probably be out of order when required. Two regional depots for storage have been acquired—one at Manchester and the other in the London district. These have between them a capacity of about 4,000,000 gas masks and facilities for their inspection and preservation. Eleven more regional store depots will be required and urgent steps are being taken to secure them. The system of distribution from these depots is now under investigation and it is proposed that the arrangement will include local store depots, each with a capacity of 30,000 gas masks. Ultimately the regional depots will be used to house the reserves of gas masks and of other stores required in connection with air raid precautions, some of which are of a bulky nature. In reply to a question in Parliament whether the gas masks would not have deteriorated before the war started, the minister replied "No. Special technical precautions are being taken so that these gas masks are in good condition."

#### Carcinogenesis

William Cramer and E. S. Horning have studied the carcinogenic properties of hormones. Estrogen is closely related chemically to some of the carcinogenic hydrocarbons. It is therefore not surprising that some of these induce estrus. But when tested by painting on the skin, the estrogens proved inactive. Subsequently Lacassagne found that subcutaneous injection over many months produced mammary cancer, even in male mice. This has been confirmed by several workers. It therefore seemed that a substance can be carcinogenic for one organ (the mamma) and not for another (the skin). To test this point, Cramer and Horning applied a dilute solution of estrogen to the skin of male and female mice for a prolonged period. The surprising result was that cancer developed in the mamma but not in the skin, and as readily in males as in females. This result indicates an organ specificity for carcinogenic agents, a fact not previously suspected. Some apprehension has been aroused as to the danger of using estrogen, but Cramer and Horning have shown that carcinogenesis requires much larger doses and much longer periods than those of therapeutic administration.

#### The Defense of Actions for Negligence

At the West London Medico-Chirurgical Society, Mr. Pearce Gould, president of the Medical Defense Union, gave an address on the defense of actions for negligence. He said that it was unfortunate that actions for negligence or threatened actions were on the increase. For this there were several causes. One was a loosening of the old time mutual confidence between physician and patient. Another was that lay persons were acquiring more knowledge of medical matters. A third was the news value of physician's peccadillos; their publication encouraged others to attack their physicians. The gravity of

## Deaths

**William Hermann Dieffenbach**, New York; New York Homeopathic Medical College and Hospital, 1900; member of the American Roentgen Ray Society; at one time professor of therapeutics at his alma mater and professor of physical therapeutics and vice president at the New York Medical College and Hospital for Women; was an adviser to the U. S. Army Medical Corps during the World War; in 1905 was a delegate and vice president of the First International Congress of Radiology at Liege, Belgium; aged 71; a founder and past president of the medical board of the Broad Street Hospital and president of the board of directors of the Community Hospital, where he died, January 13, of cerebral hemorrhage.

**Francisco Maria y Hernandez Fernandez** ☉ Miami, Fla.; Columbia University College of Physicians and Surgeons, New York, 1908; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; past president of the Pan-American Medical Association; formerly Cuban secretary of state and Cuban secretary of sanitation; at one time assistant professor of ophthalmology at the University of Havana Faculty of Medicine; formerly chief of clinic, eye department, Mercedes Hospital, Havana; had been decorated by several governments; aged 50; died, February 14, of coronary thrombosis and diabetes mellitus.

**Charles Moore Gandy** ☉ Colonel, U. S. Army, retired, Ocean View, N. J.; Jefferson Medical College of Philadelphia, 1879; entered the regular army as an assistant surgeon in 1884, was lieutenant colonel in the medical corps in 1909, colonel in 1913 and retired in 1921 by operation of law; served in the Sioux Indian and Spanish-American wars, the Philippine Insurrection and the World War; served in the office of the Surgeon General, 1912-1914; past president of the Cape May County Medical Society; aged 79; died, January 8, of chronic cardiac disease.

**Frederick Beach Burke** ☉ Detroit; Georgetown University School of Medicine, Washington, D. C., 1906; associate professor of pediatrics at the Wayne University College of Medicine; president elect of the Wayne County Medical Society; aged 54; consultant in pediatrics at St. Joseph's Mercy Hospital and Deaconess Hospital; for several years chief of staff of Children's Hospital; on the attending staff of the Receiving Hospital and the Harper Hospital, where he died, February 2, of pneumonia.

**Reginald Copeland Plummer**, Seattle; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the Washington State Medical Association, and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; past president of the King County Medical Society; served during the World War; aged 55; formerly on the staffs of the Providence Hospital and the Swedish Hospital, where he died, Dec. 26, 1936, of pulmonary and genito-urinary tuberculosis.

**James Percy McKelvy** ☉ Pittsburgh; Columbia University College of Physicians and Surgeons, New York, 1901; past president of the Allegheny County Medical Society; fellow of the American College of Physicians; director of the medical division of the Allegheny General Hospital; chairman of the board of managers of the William Harton Singer Memorial Research Laboratory; aged 67; died, January 28, in St. Luke's Hospital, Kansas City, Mo., of heart disease.

**Walter Olin Nisbet** ☉ Charlotte, N. C.; Medical College of South Carolina, Charleston, 1889; fellow of the American College of Physicians; at one time dean and professor of diseases of the digestive system, North Carolina Medical College; on the staffs of the New Charlotte Sanatorium and the Presbyterian Hospital; aged 70; died, January 18, of coronary occlusion.

**Edward Burke Bailey**, Demopolis, Ala.; University of Virginia Department of Medicine, Charlottesville, 1897; member of the Medical Association of the State of Alabama and the Southeastern Surgical Congress; president of the Marengo County Medical Society; medical director and owner of the Hand-Bailey Infirmary; aged 60; died, January 5, in Linden.

**Clarence W. Chapin**, Clinton, Ill.; Northwestern University Medical School, Chicago, 1899; member of the Illinois State Medical Society; past president of the DeWitt County Medical Society; served during the World War; on the staff of the Dr. John Warner Hospital; aged 64; died, January 21, at St. Joseph's Hospital, Bloomington, of coronary thrombosis.

**Stanley Blair Andrews**, Toledo, Ohio; Miami Medical College, Cincinnati, 1908; member of the Ohio State Medical

Association and the Associated Anesthetists of the United States and Canada; served during the World War; aged 53; on the staff of St. Vincent's Hospital, where he died, in January, of injuries received in an automobile accident in August.

**Augustine Patrick Douglas Cleary**, Canon City, Colo.; University of Virginia Department of Medicine, Charlottesville, 1892; Bellevue Hospital Medical College, New York, 1896; M.R.C.S., England, L.R.C.P., London, 1896, and F.R.C.S., Edinburgh, Scotland, 1897; veteran of the Spanish-American War; aged 66; died, January 12, in the Colorado Hospital.

**Sidney Meeker**, Memphis, Tenn.; University of Alabama School of Medicine, 1907; member of the Tennessee State Medical Association; served during the World War; physician to the Juvenile Court; on the staff of the Home for Incurables, St. Joseph's Hospital and the Gartly-Ramsay Hospital; aged 66; died, January 9, of heart disease.

**Ross A. Mitchell**, Moberly, Mo.; University Medical College of Kansas City, 1905; member of the Missouri State Medical Association; past president of the Randolph-Monroe County Medical Society; aged 55; formerly on the staff of McCormick Hospital, where he died, Dec. 8, 1936, of myocarditis.

**Alfred William Bayliss**, Buffalo; Niagara University Medical Department, Buffalo, 1889; for many years a member of the city health department; formerly on the staffs of the Sisters of Charity Hospital and the Emergency Hospital; aged 83; died, January 11, of cardiovascular disease and arteriosclerosis.

**John Priestes** ☉ Pittsburgh; University of Pittsburgh School of Medicine, 1922; fellow of the American College of Surgeons; resident physician to the Western Penitentiary Hospital; member of the staff of St. John's General Hospital and St. Joseph's Hospital; aged 38; died, January 10, of meningitis.

**Claire H. Denman**, Berkeley, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1893; also a minister; member of the California Medical Association; past president of the city board of education; formerly a medical missionary; aged 69; died, January 13, of acute dilatation of the heart.

**Lawrence M. Demarest**, South Orange, N. J.; University and Bellevue Hospital Medical College, New York, 1918; served during the World War; aged 48; died, January 14, in the United States Marine Hospital, Stapleton, N. Y., of cholecystitis, cholelithiasis and chronic appendicitis.

**William Patterson MacCracken**, Chicago; Hahnemann Medical College and Hospital, Chicago, 1887; formerly senior medical examiner for the aeronautics branch of the U. S. Department of Commerce; aged 73; died, January 31, of chronic myocarditis and arteriosclerosis.

**Chauncy Valentine Perry**, Greenfield, Mass.; Harvard University Medical School, Boston, 1928; member of the Massachusetts Medical Society; on the staff of the Franklin County Public Hospital; aged 36; died, Dec. 7, 1936, of an overdose of morphine, self-administered.

**Carl Lester Magnus Holmberg**, Brockton, Mass.; Harvard University Medical School, Boston, 1900; member of the Massachusetts Medical Society; formerly member of the city board of health; aged 62; died, Dec. 29, 1936, of aortic stenosis and chronic myocarditis.

**Herman Haughton James**, Bog Walk, Jamaica, British West Indies; Howard University College of Medicine, Washington, D. C., 1912; L.R.C.P., of Edinburgh, L.R.C.S., Edinburgh, L.R.F.P. & S. of Glasgow, 1924; aged 51; died, Dec. 15, 1936, of pneumonia.

**John Jervis Allen**, Monaca, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1891; member of the Medical Society of the State of Pennsylvania; on the staff of the Rochester (Pa.) General Hospital; aged 77; died, January 21, of cardiorenal disease.

**Elton Streett Warner** ☉ Wilkesburg, Pa.; University of Pittsburgh School of Medicine, 1918; member of the school board and for many years chairman of the board of health; on the staff of the Columbia Hospital; aged 42; died, January 2, of pneumonia.

**Joseph Tregelles Fox**, San Diego, Calif.; L.S.A., London, 1877, and M.R.C.S., England, 1878; formerly a medical missionary; aged 81; died, January 4, in the Paradise Valley Sanitarium and Hospital, National City, of pyelitis, cystitis and carcinoma.

**Henry Kajetan Seelaus** ☉ Philadelphia; Jefferson Medical College of Philadelphia; assistant professor of surgery at his

very long wavelength. Hence the problem of high voltage radiotherapy is to find the factors that are able to cause penetration into the tissues of sufficiently large quantities, which by successive "degradations" will act on the most radiosensitive cells. It is unnecessary, however, that these successive "degradations" should be very numerous. It suffices that such changes can take place. A study of the factors of penetration shows that the most advantageous changes in the expense of transmission of the current are obtained in passing from 0.5 meter to 1 meter of focal distance at 200 kilovolts or in passing from 200 to 700 kilovolts without change of distance.

Gunsett of Strasbourg described the high voltage apparatus that he used for radiotherapy. The tension is constant and the tube is a special one, attaining a voltage of 520,000 volts and 3 milliamperes. He believed that the advantages of very high voltage were the following:

1. A very marked increase of the deep dose, which at between 200 and 520 kilovolts is 30 per cent.

2. A noteworthy decrease (about 36 per cent) of diffuse radiation, which enables the skin to tolerate a higher dosage with resultant beneficial action on the deep lying cancer.

3. With 520 kilovolts one can lessen the distance up to 80 cm. and shorten the duration of the sittings, the latter being of especial importance in cases in which several fields are to be treated by cross-firing.

Mathey-Cornat of Bordeaux said that the introduction in radiotherapy of high tensions, above 200 kilovolts, and especially from 300 to 500 kilovolts, has raised many new questions of a biologic and clinical nature. The term still currently employed of "high tension" is an imperfect description of this ultrapenetrating roentgenotherapy, which combines increase of distance with that of filtration and permits sittings that are not too long in cases in which fractional treatments over a prolonged interval are indicated. From the biologic point of view it is advisable to increase not only quantitatively but also qualitatively the deep dose to be distributed in the tissues. The high voltage technic demands accuracy and safety. The tumors in which irradiation from 300 to 600 kilovolts is especially indicated are deep seated thoracic and abdominal neoplasms. The contraindications are the same as exist for 200 kilovolts. Since using the high voltage treatment, the results at the Bordeaux anticancer center have shown a 10 to 15 per cent improvement. Of eighty-five patients treated during the past two years with the high voltage currents, 65 per cent primary cures and 55 per cent of over a year's duration have been noted in cases of cancer without selection of any special localization. For certain cancers the results do not show any improvement over the period when 200 kilovolts was used. The end results cannot be determined as yet. However, although high tension radiotherapy represents a step in advance, the cancer problem remains dominated by the biology of the question.

#### The Compulsory Retirement Law

A bill will be introduced by Mr. Pomaret during the present session of the French legislature to compel the members of all the liberal professions (architects, engineers, physicians, dentists, lawyers) to surrender their diplomas at the age of 65 without any prospect of receiving a government pension. The object of the proposed law is to make room at the top for the younger members of the respective professions. The bill has encountered violent opposition on all sides and it is doubtful whether it will ever reach a vote even in the Chamber of Deputies, in which there is a strong socialist majority. The members of all the liberal professions, in addition to payment of personal property and income taxes, are subjected to a third tax termed the "patente," or license to practice tax, which is calculated on the rental value of the space occupied in practicing the given profession. It has been suggested recently that the revenue from this third tax, instead of being

paid to the government, should, in case the Pomaret bill becomes a law, be turned over to a fund from which a pension should be made to those who are forced to retire. Until the bill is actually subjected to open debate in the committee to which it will be referred for investigation as to its merits and injustice, no definite action can be taken by the organizations that represent the various liberal professions. Sufficient protests against the passage of such a law have already been made to render it doubtful whether the bill will ever emerge from the committee deliberations.

#### Irradiation of Adrenals in Obliterating Arteritis

Desplats and Langeron have employed radiation treatment during the past eight years in 200 cases of obliterating arteritis with about 62.5 per cent good results, 22.5 per cent partial results, 5 per cent failures and ten cases in which radiation could not be employed because of the presence of embolism, thrombosis or aneurysm. In diabetic arteritis, the results are almost constantly good. In thrombo-angiitis (juvenile arteritis) the results have thus far been favorable but close surveillance is necessary. In angioscleroses, many relatively good results have been obtained, and it has frequently been possible to avoid amputation. As to technic, the authors advise giving 150-250 roentgens per treatment, with a prolonged sitting. This method appeared to increase the number of successful cases.

#### Investigations of the Extent of Syphilis in a Large Urban Community

Dr. Strelow reports in the *Münchener medizinische Wochenschrift* observations from the examinations of syphilitic patients made at the University Clinic at Cologne, the largest hospital in that Rhenish city of 750,000 inhabitants. From 1921 to 1925, 15,000 cases of all kinds were received at the hospital, a patient received more than once being reckoned of course as a single case. Strelow states that the figures arrived at on the basis of this clinical material may be considered average for the entire population of Cologne. Of these 15,000 patients, 52 per cent were men and 48 per cent women. Among them there were 1,112 persons, or 7.4 per cent, who had become infected with syphilis. This proportion of syphilitic patients to the gross material fluctuated but little from one year to the next. There was a somewhat higher incidence of syphilitic infection among the men; 7.9 per cent of all male patients were syphilitic against 7 per cent of all female patients. Strange to say, there was a smaller proportion of unmarried persons among the syphilitic patients than among the hospital patients as a whole: 27.2 per cent of syphilitic male patients were single, against 40.2 per cent of all male patients, and 41.1 per cent of syphilitic female patients were unmarried, against 54.7 per cent of all female patients. Conversely, the number of syphilitic patients who had been married one time or another was greater than the corresponding proportion among all patients. The number of syphilitic patients who had been divorced was about four times the corresponding proportion among the patients as a whole.

As to age, the largest number of syphilitic men (28 per cent) were in the fifth decade of life and the largest number of women were in the third decade. Positive Wassermann reactions produced by early syphilis were observed in 76 per cent of 572 men and in 84 per cent of 470 women examined. The more frequent positive reactions among the women may be ascribed to their having received fewer treatments and this in turn may be due to the fact that syphilitic women are less apt to be familiar with the nature of their illness. According to the anamneses the infection had remained latent in more than 50 per cent of the men and in an even greater proportion of

### ARGYRIA AND LIPOID PULMONARY DISEASE FOLLOWING INTRANASAL MEDICATION

*To the Editor:*—Pity the persons today having what is termed the common cold. Especially unfortunate are infants and children. No sooner does a child have a snuffle than the mother, who may have been instructed by a physician or local druggist, begins flushing the nose with various popular nose remedies. A timely report by W. J. Kerr (*The Common Cold*, *THE JOURNAL*, Aug. 1, 1936, p. 323) asks: "Since it is apparent that no rational means are available to prevent or treat a common cold on the basis of the hypothesis of infectious origin, isn't it urgent to go back to fundamentals and start anew?" It is well to recall that a few decades ago the physician in treating a cold prescribed the usual supportive measures, letting the nose "run" at will. Who can question the rationale of permitting natural drainage?

Little is known concerning the function of the erectile tissue situated over the turbinate bones of the nose. Every one, however, recognizes that it is an exceedingly sensitive and delicate vascular structure. It is thought that it not only prepares the incoming air for the respiratory tract but also is in some way related to the function of the skin, lungs and kidneys in regulating the heat and water in the body. Another structure equally important in the physiologic as well as defense functions of the body is the ciliated epithelium in the nose. It has been shown that even saline solutions and distilled water will interfere with the normal function of the cilia. What is going to happen to these important structures in the nose when they are repeatedly doused with various irritating or even nonirritating chemicals and oils? Time alone will bring out the resultant effects and thus decide their fate. It always has proved true that any tampering with the purposeful function of an organ sooner or later leads to untoward consequences.

Appearing in *THE JOURNAL*, Dec. 5, 1936, was one of a series of articles prepared by eminent authorities for the purpose of extending information concerning the official medicines. They have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and *THE JOURNAL*. This report, by Clyde A. Heatly, was entitled "Local Medication of the Upper Respiratory Tract." The introductory sentence suggested that the general practitioner confine his use of local medication for the most part to acute infections of the upper respiratory tract. Under the subject acute rhinitis the author said "The commonly used silver colloids mild protein silver and neosilvol (10 per cent solution) have been found experimentally to destroy epithelium and to impair ciliary action. Nevertheless, they will continue to be widely used for their recognized empirical value." There was no statement or word of caution concerning the likelihood of argyria from their continued use. Cases of argyria from intranasal and pharyngeal applications of silver preparations have become increasingly prevalent during the last few years (Gaul, L. E., and Staud, A. H.: *Clinical Spectroscopy*, *THE JOURNAL*, April 20, 1935, p. 1387). There is no successful treatment for these unfortunate victims, who of late include a fair number of discolored children. Silver preparations were again mentioned for the local treatment of acute infections of the throat. The following, reported through the courtesy of Dr. Juan Figueroa of Havana, is a typical case history in argyria: B. M. O., a Cuban druggist, aged 46, had had hay fever for sixteen years. In 1929 an ear, nose and throat specialist "recommended" the use of a 3 per cent solution of mild protein silver, 30 drops twice a day, in both nostrils. He followed this treatment for two years. In 1931 the strength of the solution

was doubled. In 1932 he noticed the first signs of discoloration, which gradually became more marked. He was ordered to stop the medication in 1934. Fifteen additional cases have been reported and observed since 1935.

In addition, Heatly emphasizes that present experimental studies have demonstrated that many of our accepted local preparations are actually destructive to epithelium and favor infection by impairing ciliary activity. He refers to the commonly used nasal oils containing liquid petrolatum, eucalyptol, menthol, camphor and thymol as having this effect. He also points out that the indiscriminate use of liquid petrolatum as nasal drops in infancy is not entirely without danger in view of the numerous reported cases of lipoid pneumonia from accidental inhalations.

Even though experimental data and actual clinical and pathologic observations stress the outcome of using oily preparations intranasally, strangely enough the author has included prescriptions containing these very substances. More or less paralleling the popularity and wide usage of oily preparations in the nose have been not only the increasing number of cases of sinusitis and lipoid pneumonia but also bronchopulmonary disease attributed to their use (Tchertkoff, I. G., and Ornstein, G. G.: *Bronchopulmonary Disease Attributed to the Use of Intranasal Instillations of Oily Substances*, *Sea View Bull.*, January 1936). During 1936 there have been additional cases reported and observed. In view of these facts it seems out of place and hazardous to recommend such medications to physicians, who in turn may advise their home use by parents.

Today proprietary remedies for the nose are advertised blatantly to the profession and public and sold by druggists indiscriminately. If the common cold proves to be a constitutional reaction to fortify and keep mobile the defense mechanism of the human body, some one has certainly erred.

L. EDWARD GAUL, M.D., New York.

### REQUESTS FOR REPRINTS

*To the Editor:*—Under this title in *THE JOURNAL* of January 16, page 224, Dr. W. A. Bastedo has reported that he has been irritated by requests for reprints which were not accompanied by return postage, and that he throws the post card requests in the waste basket.

I have observed that many earnest workers in laboratories and in the clinical sciences keep files of reprints of articles pertaining to the subjects in which they are particularly interested.

My associates and I too receive numerous post card requests for reprints, and from some of the best known men and laboratories in the country. I disagree with Dr. Bastedo. I feel that special studies should be encouraged by the free distribution of reprints to any one interested enough in any given line, as long as it does not become too much of a financial burden on the author. This the author can control by the number of reprints ordered.

ROY D. McCLURE, M.D., Detroit.

### FACIAL INJURIES

*To the Editor:*—In his paper on facial injuries in *THE JOURNAL*, January 9, Dr. C. L. Straith refers to Dr. J. J. Shea (*THE JOURNAL*, Feb. 7, 1931, p. 418) as "elevating the malar bone by means of an antrum trocar inserted into the antrum through the nose."

In *THE JOURNAL*, Dec. 21, 1929, I described the method reported by Dr. Shea. In the same article I mentioned the method Dr. Straith calls his—entering the antrum through the lateral alveolar margin—and gave reasons for not using it.

Entering the antrum with a trocar (preferably through the nose) is a proper procedure; however, elevating the fractured

over type X and its subspecies. Conversely, type X and its subspecies predominated in various forms of bronchitis and bronchopneumonia. Types I and II preponderated in meningitis, type I alone in peritonitis.

### New Aspects of the Castration Question

As reported previously, data on the favorable results of castration are being assembled in Germany. However, these data are still to be appraised with the utmost caution in view of the brief period of observation which they represent and also as the interval between the operation and the first manifestation of its effect is far from uniform. The effect usually is first manifested only after an interval of months, but in many cases a period of years may elapse. Dr. Kopp, a jurist, whose article appeared in the *Deutsches Aerzteblatt*, stresses the paramount

#### Number of Castrations Performed in Germany to August 1936

Year	1934	1935	1936
In Germany .....	672	324	120
In Berlin .....	141	135	37

importance of a careful choice of the criminals to be castrated. The most frequently encountered sex offenders are exhibitionists, rapists, and persons guilty of crimes against children. According to Dr. Schlegel, medical superintendent of the Berlin Prison Hospital (*THE JOURNAL*, Feb. 2, 1935, p. 412) the libido became extinguished in some 90 per cent of castrated persons about four weeks subsequent to the operation; in a few cases it was enfeebled but became obliterated only after four months. The working ability of the prisoners was restored two weeks after operation. The morale of the castrated persons was good throughout; several among them who had previously showed a disposition to grumble became more friendly and tractable after the operation.

#### The First Congress of Structural Surgery

The first Congress of Structural Surgery proved completely satisfactory to both its organizers and its members. In addressing the opening session, Dr. Coelst stressed the importance of the new designation of this particular branch of surgery, a branch that is not to be confused with simple repair surgery, with general surgery or with purely esthetic and plastic surgery. Structural surgery includes all operations that concern morphologic changes and functional amelioration both in the internal bodily cavities and on the bodily periphery. Dr. V. Cheval, a member of the Academy of Medicine, after having furnished an account of plastic surgery in its relation to otorhinolaryngology, expressed his pleasure at the replacement of the term "esthetic surgery" by the term "structural surgery." Among those who then expressed their approval of structural surgery and discussed various aspects of the field were Professor Remynse of Rotterdam, Dr. Esser of Monaco, Professor Héger-Gilbert and Dr. Watry, both of Brussels, and Dr. Dupuy de Frenelle of Paris. Among the principal topics of discussion were the testing of free grafts, traumatic lesions of the face, and the treatment of cleft palate.

Mr. Dufourmentel of Paris has made a study of conditions under which transplanted tissues are most likely to take or survive. He sought first to determine the circumstances that underlie the successful taking of a transplant: the physiologic condition of the selected graft, the way in which it is adapted to the field of transplantation, the condition of this field and so on, and, if a homograft is used, the importance of the reciprocal reactions of the tissues of the donor and the tissues of the recipient. He emphasized in particular the importance

of keeping the field of transplantation absolutely free from foreign bodies, with especial regard to microscopic bodies. He described the condition of transplanted tissues that had been observed after varying periods of time up to twenty years and more. He concluded that a transplant may actually become naturalized provided the operation has been performed under favorable circumstances.

Dr. Straith of Detroit discussed the treatment of facial injuries: The frequency of traffic accidents has increased the number of traumatic lesions of the face that require surgical treatment. Disfiguration is often a source of mental anxiety and often enough may even lead to a psychic handicap that mars the social life and career of the victim. The end result will depend on the meticulous care with which diagnosis is made and the proper therapeutic measures, beginning with the first aid treatment, are instituted. If infection or some other complication should prevent initiation of an optimal course of treatment immediately following the trauma, plastic intervention should be postponed. No surgical treatment should be undertaken unless it can be carried through to completion. From beginning to end, every effort should be made to diminish the cicatricial formations and to return the patient to society as little disfigured as possible and without needless delay.

Dr. Wardill of Newcastle-on-Tyne discussed the treatment of cleft palate: In subjects presenting cleft palate the distance between the superior maxillae is greater than in the normal skull. There is a smaller amount of soft tissue filling the interstice. The anteroposterior and transverse diameters of the nasopharynx are increased. The objective of operative treatment is to create a functioning nasopharyngeal valve. This can be effected by use of the following procedures: rapprochement of the sides of the nasopharynx and the projection of the pharyngeal wall, the restoration of the soft palate in a position from which it can easily attain the posterior wall of the pharynx and thus close the valve, and the freshening of the borders of all the soft tissue at the level of the movable parts. Both sides of the nasopharynx are brought more closely together and the pharyngeal wall is projected forward by a pharyngoplasty. This operation should be performed before the child has learned to speak; that is, in the third year or earlier. Infants treated by this method acquire normal speech and the need for relearning is obviated.

#### Liaison Between Departments in Sanitary Affairs

The liaison between the Ministry of Public Health and all departments which, on no matter what head, are concerned with questions of hygiene and public health, constitutes, in theory at least, an extremely desirable innovation.

In several foreign countries some such measure of centralization exists and if these arrangements are by no means perfect they at least represent notable advances in the right direction. The reorganized Belgian health ministry may be expected to produce optimal results, although it represents so far only a first step along the path of centralization. But no matter how far this policy is carried in future, the fact cannot be overlooked that there will always remain certain types of service which it will not be possible or which it would not be desirable to sever from the ministry in which they are integrated. Some substantial and encouraging results have already been obtained along these lines without any intervention of a regulatory character, thanks to a generous breadth of understanding of hygienic and public health problems on the part of the men whose duty it is to uphold these things.

The time seems ripe on the occasion of the creation of the department of public health to organize suitably close cooperation between the services involved, in such a way as to assure a maximal efficiency and to coordinate all common efforts.

The establishment in conjunction with this department of an interministerial committee on which would serve all the

155

and eyes. It has been observed that railroad track workers employed in hot summer months around freshly impregnated ties may develop a dermatitis from emanations of the chemicals used for water proofing and fire repelling. This occurs in the absence of direct contact. The present situation involving impregnated conduits is comparable.

Another item worthy of consideration grows out of the possible use of inorganic chemicals as constituents of the impregnating materials for fire prevention. Zinc chloride may be so used. When completely dry, zinc chloride dust might be produced on wood or paper impregnated articles; blown on the skin, a dermatitis may arise.

In the trade described, the occurrence of an industrial dermatitis is not questioned—it is expectable; but a dermatitis of the face without eye irritation and without an appearance on the hands and arms is doubted. For clarification purposes it is suggested that patch tests be carried out on both afflicted and control groups, using shavings from untreated conduits, treated conduits before and after outside exposure, impregnating pitch, and so on. In the absence of positive tests, other irritants or sensitizers should be sought. In case the dermatitis is traced to dust or vapors blown off the conduits on the faces of workmen, reasonable protection may be procured by smearing the face with a tenacious grease, such as hydrous wool fat, prior to the beginning of any work period. Such grease will serve as a fairly effective barrier, preventing contact with the skin.

#### TREATMENT OF ANEMIAS

*To the Editor:*—A man, aged 75, has a typical "pernicious anemia," according to the blood picture, gastric examination and nervous symptoms. He is taking large quantities of liver daily (orally in capsule form) and hydrochloric acid (dilute) three times daily. The blood picture remains normal except for occasional remissions. The gastro-intestinal symptoms of nausea, diarrhea (occasional) and anorexia persist, as do certain nervous manifestations such as temporary aphasia and mild mental depression. He complains that every morning at 10 o'clock he feels drowsy and languid with some clouding of the mental faculties, and after 4 p. m. he feels mentally alert and fairly comfortable. Do you think intramuscular liver would be of value and can you account for the periodic 10 a. m. to 4 p. m. condition?

P. R. BRIGGS, M.D., Hartland, Maine.

**ANSWER.**—The adequate treatment of a patient with primary pernicious anemia is an individual problem which must be guided by the response of the patient. From the history of the case cited there is every reason to change from the oral to the intramuscular method of administration. In patients whose gastro-intestinal symptoms are not as pronounced the intramuscular use of liver extract is advisable, as this method assures the physician that absorption will be more complete than when the extract is taken by mouth. With the marked atrophy that occurs in the gastro-intestinal mucosa, abnormal bacterial flora and the rapid peristaltic movements, absorption must be impaired. In this particular case the number of capsules required by mouth may in themselves aggravate the gastro-intestinal symptoms of nausea, anorexia and diarrhea described.

While the dosage of hydrochloric acid was not noted, it should be appreciated that as a rule too little acid is given. The amount of diluted hydrochloric acid U. S. P. is seldom given in quantities which would equal that produced by a normal person. Not less than from 6 to 12 cc. should be given three times daily, well diluted in water. In a considerable proportion of cases the administration of hydrochloric acid may markedly alleviate the gastro-intestinal symptoms, including the disappearance of the glossitis and sore mouth. Virtues of acid therapy other than these may be said to rest on an uncertain basis.

It would seem advisable to administer iron (inorganic) in some form, as often patients with persistent gastro-intestinal symptoms have in addition a deficiency of iron and thus lack this element for the maximum production of red blood cells and hemoglobin. Iron ammonium citrate, from 4 to 6 Gm. daily, preferably in capsule form, or ferrous sulfate, from 2 to 3 Gm. daily, are two among many of the soluble preparations that will be found satisfactory.

The central nervous system involvement, of course, is characteristic of Addisonian pernicious anemia, though the aphasia and mental depression described during remission may possibly be attributed to the age of the patient. Cardiovascular changes especially involving the cerebral vessels may produce similar signs and symptoms without the presence of pernicious anemia. Publications dealing with arteriosclerosis as a complicating factor in the treatment of pernicious anemia point out that such patients require larger daily amounts of liver extract, and about the best

that can be expected with regard to the central nervous system is to see that the red blood cells and hemoglobin percentage are kept as near normal as possible (red blood cells 5,000,000, hemoglobin from 85 to 90 per cent). By such treatment it is usually possible to prevent further progress of the lesions of the central nervous system, though the complete disappearance of these symptoms cannot be anticipated in a patient so advanced in age. As to why the attacks of aphasia, drowsiness and the like should occur from 10 a. m. to 4 p. m. it is not possible to say unless the physical activities between these hours produce changes in the cerebral blood supply which are associated with or accentuated by arteriosclerosis of the brain. It might be advisable to obtain samples for blood sugar determination at these times, though disturbances in carbohydrate metabolism are not common in pernicious anemia. Pathological Physiology and Clinical Description of the Anemias, by W. B. Castle and G. R. Minot, Oxford Medical Publications, gives an excellent review of the general care of patients with various types of anemia, which might be helpful.

#### DYSPNEA

*To the Editor:*—A man, aged 39, has complained for the last year of a feeling of suffocation, that is, the inability to get air into the lungs, especially when he arises in the morning. The suffocating feeling does not change either when lying down or sitting up. This occurs at varying intervals, ranging from half an hour to several hours. There are some days on which he has none of these symptoms. Accompanying this feeling of suffocation, he may have an occasional dizzy spell and palpitation of the heart, and he quite often has a feeling of anxiety and becomes frightened. In the intervals he is quite cheerful and states that he would be perfectly all right if it were not for the difficulty of getting air into his lungs. He has had dyspnea on severe exertion. A year ago, when I examined him, his blood pressure was 144 systolic, 85 diastolic, pulse 165, and weight 138 pounds (62.6 Kg.). He has not lost any weight during the last year. He had all his teeth removed in 1932 on account of pyorrhea and dental caries. He had a compound fracture of the radius and ulna near the elbow in 1915. He shows inability to pronate and supinate. In 1924 he was caught between a wall and a trolley car and was said to have had several of his vertebrae dislocated. He was treated by a chiropractor for two months, but he has not been bothered with his back lately. He had influenza in 1918. He was bitten by a dog in 1930. Probably no ill after-effects have been apparent. He had his tonsils removed by diathermy in July 1935. The cardiorespiratory system is otherwise negative. The gastro-intestinal tract is practically normal. The genito-urinary system is normal. He has been sleeping well at night. On physical examination his heart, lungs and abdomen are negative to abnormalities. His eyes show internal and external nystagmus. His eyesight has always been poor. The left optic nerve on the temporal side is pale; the pupil reacts to light and slightly to accommodation. He has conductive and receptive deafness in both ears. He has sclerosis of both ear drums. His mouth is normal. The thyroid gland is uniformly but slightly enlarged. The lumbar region is normal. He is able to bend his spine in all directions with ease. Coordination of muscles is normal. The knee jerks are hyperactive. There is no ankylolysis. From January 6 to February 3 he was given aqueous solution of iodine, three drops three times daily. His pulse was from 70 to 100, the blood pressure 145/75, and his weight 138 pounds. There was some noticeable diminution in the size of the thyroid but no improvement in breathing. The basal metabolic rate was —19 and —15, Feb. 10, 1935 (Sanborn). His pulse was from 84 to 92, the blood pressure 140/85. He was given 1 grain (0.065 Gm.) of thyroid extract daily for several weeks and phenobarbital with apparently a decrease in the size of the thyroid. Occasionally when he had one of these spells in breathing he would have clonic and tonic contractions in the muscles of his arms and legs, which would last about five minutes. This occurred once or twice, but he was reported not to be unconscious during one of these attacks. The basal metabolic rate several weeks after treatment with thyroid extract was +5 and +9 (Jones). The thyroid was much smaller. The hemoglobin in February 1935 was 80 Tallqvist, 56 Sahli. The red blood count was 3,060,000; the Wassermann and Kahn reactions were negative. His voice is normal, with no sign of hoarseness. His vocal cords are apparently in the midline and show no paralysis. At the present time the patient has a good color and is cheerful, and only for his difficulty in breathing he would be all right. The roentgenogram of the chest showed no masses in the mediastinum or any enlargement that would cause pressure. He has stated in the past few weeks that he has had a little difficulty on one or two occasions in swallowing his food, either liquids or solids. Examination of the bronchi, trachea and the esophagus was negative. The roentgenogram of the chest shows no substernal thyroid gland enlargement or mediastinal masses that would cause any pressure on the upper respiratory tract. His difficulty in breathing has become more marked lately and his attacks more frequent. His thyroid gland does not seem to be as large as it was formerly. Please omit name and address.

M.D., Connecticut.

**ANSWER.**—A reply to this question involves a discussion of the causes of dyspnea. The question differentiates between the dyspnea of severe exertion and the difficulty in breathing that constitutes the patient's chief complaint. Dyspnea, however, means difficulty in breathing regardless of the respiratory rate, so the patient's chief complaint must be regarded as dyspnea.

less of the form (either cutaneous or subcutaneous) of application of the treatment. The development of blastoma was not in direct relation with the intensity and extension of the general organic lesions. The tumor developed more rapidly and extensively in animals with small and few organic lesions than in those which had extensive lesions in great numbers.

### Surgery of Pulmonary Tuberculosis

Professor Pototschnig, at a meeting of the Federazione per la lotta contro a tubercolosi, reviewed the progress in surgery of pulmonary tuberculosis during the last twenty years. The main object of the surgical treatment is to induce regression of tuberculosis by placing the lung in functional rest by collapse. Surgical treatment is resorted to with the same aim as that of artificial pneumothorax. It is resorted to when the latter cannot be performed or when the results of artificial pneumothorax are incomplete or insufficient. The speaker discussed the indications, advantages and disadvantages of the several surgical methods resorted to in treating pulmonary tuberculosis, with special reference to resection of the phrenic nerve, alcoholization of the intercostal nerves, scalenotomy, apicolysis and the operation of Jacobaeus. According to the speaker, surgery of pulmonary tuberculosis cannot be separated from general surgery. Close collaboration between the pulmonary tuberculosis specialist, the roentgenologist and the surgeon is important, especially in sanatoriums.

Prof. Francesco Pentinalli was recently appointed professor of general pathology at Naples University.

### BUCHAREST

(From Our Regular Correspondent)

Jan. 23, 1937.

### New Health Insurance Bill

As the law now stands, any employee who is incapacitated either through illness or by accident may claim sick benefit for six weeks no matter how many years he has been employed. A bill has been put before the Chamber of Deputies which proposes that ten years' employment shall entitle the employee to eight weeks' benefit, and every further five years of employment shall entitle the employee to a further week's benefit. Thus after thirty years' employment twelve weeks' benefit may be claimed. The employee will also be entitled to a further two weeks sick leave without pay, during which time his position must not be filled and he cannot be given notice. After two years' employment, maternity benefit is to be paid. An insured person who loses his employment will still be eligible for benefits for his employment for a quarter of the total period over which he has paid contributions, with a minimum of twenty-four months. According to present regulations the period is fixed at thirty months. The new system has been in force in Czechoslovakia for some time, where it is found to work well. Another suggested innovation is that contributors of ten years' standing who lose their jobs at the age of 55 should after twelve years' unemployment automatically become eligible for the old age pension, while for women the age limit is to be 54.

### Medical Gymnastics for Mentally Deficient Children

At the recent meeting of the Bucharest Pediatric Society, Dr. Calimanesco stated that, in the treatment of backward or mentally deficient children, medical gymnastics is useful as a prelude to physical education. The treatment must of course be strictly individualized. Its effect is to develop the latent potentiality of the brain cells. Increase in muscular power goes hand in hand with progress of mental development and improvement in the child's sensory condition. The chief aims of medical gymnastics in cases of mentally deficient children

are to aid in developing the efficiency of the motor, sensory and psychic elements of the cerebrospinal system, the sympathetic system, and generally to improve the constitution. The exercises are passive manipulations, mechanical shaking and strong vibration applied over the brain and spinal cord, and local nerve friction. Auditory and visual stimulation is afforded by telling the child to perform or to imitate movements. Active and passive, or resisted, movement of the joints may be associated with other forms of treatment.

### The Campaign Against Venereal Diseases

The Commission on Venereal Diseases held its annual meeting recently. The secretary of the commission said that he thought that venereal diseases were somewhat less prevalent than in the years following the World War, but on this point it was difficult to speak with certainty; the statistics of deaths certified as due to syphilis are unreliable. He remarked that although large subscriptions are given to the combating of other diseases, little has been done with regard to venereal diseases. If it is desired to cure syphilis and get rid of the disease, said the report, anything that would aid early diagnosis ought to be at a patient's disposal without expense to him. In any scheme for the efficient treatment of the diseases, the establishment of night clinics in the large cities—Bucharest, Galatz, Jassy, Cluj—was essential.

The commission stated that though it had formerly been in favor of notifying all cases of venereal disease to the health authority, it had modified its view because it was convinced that notification would deter sufferers from seeking proper advice and would lead to increased recourse to quack treatment.

As to the education of public opinion with regard to venereal diseases, the commission stated that in the first place the infected person must be instructed. It should be made compulsory for medical practitioners to supply to every patient suffering from venereal disease printed instructions as to the nature of his disease and as to the measures he should adopt to avoid spreading it; copies of these instructions should be supplied gratuitously to physicians. Secondly, it suggested that all institutions where there are a large number of employees or institutions, such as colleges and universities, ought to have some course of lectures explaining the dangers of venereal disease. It was also of the greatest importance that the standard of knowledge of these diseases in the medical profession should be raised; in the past the teaching given was inadequate, but steps were now being taken in some of the more important hospitals to improve that situation.

## Marriages

RASMUS V. WILLIAMS to Mrs. Helen Smith Merriam, both of Rushford, Minn., in Chicago, Dec. 27, 1936.

LEWIS WILLIAM GLATZAU to Mrs. Winnifred McDonald, both of Daytona Beach, Fla., Nov. 12, 1936.

JOHN A. SIMPSON, Athens, Ga., to Miss Mary Louise Schuman of Savannah, in December 1936.

JOSEPH THOMAS WHITFIELD to Miss Virginia Louise Evans, both of Nashville, Tenn., Dec. 30, 1936.

WELDON PAUL SANGER, Durham, N. C., to Miss Mary Ann Carr of Atlanta, Ga., in December 1936.

JOHN C. WEST to Mrs. Elizabeth Ann Patterson, both of Batavia, Ill., in Wheaton, Dec. 23, 1936.

RALPH BERNARD GARRISON to Miss Evelyn Louise Blackley, both of Hamlet, N. C., Nov. 14, 1936.

CLIFFORD H. BEACH, Richmond, Va., to Miss Jebbie Whitehead of Chatham, January 30.

ANDREW B. SMALL, Dallas, Texas, to Miss Nancy Wright, Dec. 15, 1936.

BRAIN ABSCESS AND TREATMENT IN BRONCHIECTASIS  
—CLIMATE OF TUCSON

*To the Editor:*—My brother, aged 23, developed bronchiectasis following pneumonia in 1934. Since then he has tried most of the routine treatments, including postural drainage, bronchoscopy and autogenous vaccine injections, and he has lived in Tucson, Ariz., for the past two winters. However, he does not feel improved clinically, though the x-ray plates show some evidence of lessening of the process. The latest plate taken (January 29) is reported thus: "There are clouding and mottling and apparently some bronchial dilations in the area of the descending bronchial branches and spreading out over the dome of the diaphragm on the right. A single fusiform dilatation is seen at the left base." The conclusions are: "Bronchiectasis, moderate in degree, without apparent inflammatory reaction, right base. Bronchiectasis, minimal, without inflammatory reaction, left base. Also, thickened pleura and slight pleural adhesions at right costophrenic angle." Clinically, the patient does not look any worse than he did before onset of the condition; his breath is not foul, although the sputum he brings up; his finger tips are not clubbed, and he shows no cyanosis. He is attending college at Tucson. What percentage of danger of cerebral abscess is there? Is there any other climate, outside the United States if necessary, that might do him more good than that of Tucson? He tells me that there is a higher humidity this year than ever before. Is there any other nonsurgical procedure that should be attempted first? Please omit name and address.

M.D., New York.

**ANSWER.**—The fact is well established that brain abscess may be a complication of bronchiectasis; however, it apparently is not a frequent one in the milder cases. Although the mechanism that results in brain abscess is not definitely known, it is believed to be due to infected emboli from the area of disease through the left side of the heart, the aorta and the carotid artery. Others are of the opinion that, since paranasal sinuses are frequently involved in patients who have bronchiectasis, brain abscesses may result from the sinus infections.

If careful examination of the fetid sputum should reveal spirochetes and fusiform bacilli, benefit may be derived from administration of the arsenicals, with particular reference to controlling the odor of the sputum; in some cases definite clearing of the x-ray shadows has been reported. However, when marked dilations are present it is too much to hope for their disappearance through such treatment. When the arsenicals are used, the best results are obtained from small doses. When fusiform bacilli and spirochetes cannot be demonstrated in the sputum, autogenous vaccines have been employed with some apparent success. Iodized oil introduced into the bronchial tree once every five to ten days, until ten or twelve administrations have been given, is worthy of a trial when the disease is not coming under control by other methods of treatment. Iodized oil probably acts as a lubricant and prevents obstruction of ramifications of the bronchi by mucous plugs. It is believed also to coat the lining of the bronchial tree and thus protect it from irritation. Since the oil has a higher specific gravity than mucus and other material in the ramifications, it gravitates to the most dependent parts and thus facilitates the removal of infected material, thus aiding in the prevention of absorption of toxins.

The climatic conditions at Tucson, Ariz., are as good as can be found anywhere in the world.

## POISONING WITH BARBITURIC ACID DERIVATIVES

*To the Editor:*—I should appreciate some communication in your columns relative to specific measures of value in the treatment of poisoning with the barbiturates. I have understood that picrotoxin has been used and I should appreciate some comment on its value. I have recently read the article in *THE JOURNAL* giving the Cook County Hospital therapy, but this article does not give any form of treatment that will specifically combat such poisoning. Please omit name. M.D., Illinois.

**ANSWER.**—There are at least four differently acting possible antagonists that might be of value in the treatment of barbiturate poisoning, and among these picrotoxin is not by any means the most important or the best established (Status of Picrotoxin, Report of the Council on Pharmacy and Chemistry, *THE JOURNAL*, Aug. 1, 1936, p. 354). Caffeine with sodium benzoate, given intramuscularly in doses of from 0.2 to 0.4 Gm. every two hours, is perhaps the most rational and safest one. The French have been employing, with reported good success, doses of strychnine sulfate, as high as 10 mg. injected every hour or two. Recovery has occurred after total dosages of 170 mg. (!) and even more, given in the course of several days, doses that would have produced convulsions and death in normal persons. The soluble camphor derivatives, such as metrazol and coramin, also have an experimental as well as clinical background; and again large dosage is being advocated, e. g., from 10 to 15 cc. of coramin, partly intravenously and partly intramuscularly, which doses may be repeated in from half an hour to one hour as required. The occurrence of

muscular twitching indicates temporary cessation of administration of these convulsants. In desperate cases one may employ such remedies in succession, provided the results are carefully watched.

## DIPHTHERIA OF VAGINA

*To the Editor:*—Please advise me with regard to treatment of the following case, evidently a chronic vaginitis due to the diphtheria bacillus: A woman, aged 23, otherwise apparently healthy, has had a leukorrhea for the past eighteen months. Repeated smears have been negative for the gonococcus. Hanging drop preparations were negative for *Trichomonas vaginalis* and the reaction was persistently acid. The condition was considered probably due to a fungus and numerous antiseptic solutions were employed, including merthiolate suppositories and phenylmercuric nitrate. About two months ago further bacteriologic studies were made and smears were reported positive for bacillus diphtheriae. A culture was then made and this was also reported positive for the diphtheria bacillus. The patient was given 20,000 units of diphtheria antitoxin and forty-eight hours later a solution consisting of one part of tincture of iodine to two parts of glycerin was applied locally. A cleansing douche was then used regularly for several weeks. Marked improvement followed this treatment, but the condition did not entirely clear up and has now regressed until it is about as before the antitoxin was given. A recent smear was again reported positive for the diphtheria bacillus. The exudate is not profuse. It is white and of a caseous consistency. I will appreciate greatly any suggestions as to further treatment.

M.D., Georgia.

**ANSWER.**—Genuine diphtheria of the vagina is rare, but the bacteriologic studies in this case would seem to leave no doubt as to the correctness of the diagnosis. The chief reliance in treatment must of course be the use of diphtheria antitoxin, and it would seem wise to repeat the former dosage of this substance after determining possible sensitivity, especially as such definite improvement then followed its use. In addition to such local antiseptic and cleansing measures as have been used, the employment of lactic acid douches, in a strength of from 0.5 to 1 per cent, may be of benefit.

## ACUTE GRANULOPENIA

*To the Editor:*—We recently had in our hospital a white woman, aged 48, with an acute fulminating agranulocytic angina characterized by sore throat and marked glossitis. The throat clinically appeared to have an acute streptococcal infection with exudate on both tonsils and the post-pharyngeal wall. The tongue was markedly swollen, so that it could not be protruded from the mouth, inhibiting both speech and swallowing. The floor of the mouth was edematous, and there was an associated cervical adenitis. The temperature ranged from 104.4 on admission to about 102 before death. The tongue became progressively worse and gangrenous appearing on its dorsal surface. The patient had been taking tablets for reduction of weight and I am attempting, if possible, to ascertain their nature. The blood count revealed 4,700,000 red blood cells, 250 white cells, all lymphocytes; no granulocytes were seen on smear. The count repeated again shortly after admission revealed only 50 cells with a complete agranulocytosis. We gave penicillinoteid transfusion. However, the patient died about thirty-six hours after admission. What I would like to know is: 1. Is glossitis a usual feature of agranulocytic angina? 2. What drugs to date have been proved factors in causing agranulocytic angina? 3. Cecil states that one third of these patients have positive blood cultures. This patient had a hemolytic streptococcus septicemia. Would this be primary or secondary as a terminal event? 4. What is the lowest white cell count reported in the literature on this condition? 5. What is the final status of penicillinoteid? Has any other more effectual preparation supplanted it—and altered the prognosis?

P. G. BAKER, M.D., Hartford, Conn.

**ANSWER.**—1. Vincent's or streptococcal infections commonly develop in the mouth, involving the posterior nasopharynx, soft palate, gums, and not infrequently the tongue during an acute agranulocytic episode.

2. Aminopyrine, dinitrophenol, benzene, acetanilid, arsenphenamine, neoarsphenamine and certain proprietary mixtures of aminopyrine and barbitol preparations have all been reported in an etiologic relationship to acute granulopenic states.

3. A survey of the literature reveals more than 70 per cent positive blood cultures in cases of acute granulopenia in which this examination was recorded. A primary bacterial focus followed by septicemia may overwhelm the bone marrow and produce a secondary and terminal leukopenia; however, it has been definitely proved that in many, perhaps in the great majority, of instances of agranulocytic angina, the granulopenia precedes the actual invasion of tissues and blood stream by bacteria.

4. Cases have been reported in which serial blood studies were made without disclosing a single white cell after a prolonged search of a single drop of blood.

5. Whether nucleic acid derivatives act as specific granulopoietic stimuli or simply as nonspecific irritants, there can be little doubt in the mind of the physician who has had a con-

alma mater; fellow of the American College of Surgeons; on the staff of St. Mary's Hospital; aged 40; died, February 14, of pneumonia.

## NONUNION AFTER FRACTURE IN DIABETES

*To the Editor:*—A man, aged 73, single, has had diabetes for eight years, kept well under control. The diet consists of protein 79 Gm., carbohydrate 141 Gm. and fat 100 Gm. daily. The diet contains 240 Gm. of milk three times a day and also all proper vitamins. The amount of insulin is 20 units before breakfast, 8 units before the noon meal and 10 units before supper. The blood sugar is 135 mg. fasting. The body weight appears to be about right. The temperature is 98 F., pulse from 70 to 74, and respiration 20. He has no goiter, but the metabolic rate was plus 23 in April. March 27 he sustained a fracture of the right femur. Since then the fragments have been in a Hodgen splint, which keeps them in fair position. July 5, x-ray examination showed no new bone formation. At that time the blood calcium was 7.8 mg. (normal would be from 9.5 to 10 mg.). Since then I have given the patient 15 grains (1 Gm.) of calcium gluconate and 10 drops of viosterol three times a day. July 25 the blood calcium was 7.47 mg. Still there is no new bone formation. What can be done to cause new bone formation? Please omit name.

M.D., Missouri.

*ANSWER:*—This may be merely a delayed union, and long and continuous use of conservative treatment may result in union. It is not stated whether the fracture is through the neck, through the intertrochanteric region or through the shaft of the femur, but the fact that treatment with a Hodgen splint maintains good position would indicate that the fracture is in the shaft. If union becomes too much delayed, it would be wise to drill several holes in each fragment with a one-eighth inch drill. This frequently stimulates the growth of callus and hastens union. If definite nonunion results, an autogenous bone graft may be necessary, and the indications and the contra-indications for an operation of such severity must carefully be weighed, before advising it.

## BENIGN PLAQUES OF THE TONGUE

*To the Editor:*—A child, aged 4 years, has for the past few months had what appears to be a ringworm of the tongue. It starts as a slight depression on the tongue, smoother in appearance than the rest of the surface. It gradually spreads about 3 mm. in thickness, the center becoming normal and finally covering half of the tongue. This condition lasts from two to three and one-half weeks and disappears. There are often four or five of these lesions at a time or successive crops following one another. It gives no inconvenience to the child. All other physical signs are negative and irrelevant. The parents are worried for fear it may develop into something else later. I have not been able to find a description or the treatment of this condition in any of the books on hand. Please discuss. Kindly omit name.

M.D., California.

*ANSWER:*—The symptoms detailed conform, on the whole, to a clinical description of the condition known as transitory benign plaques of the tongue, or glossitis areata exfoliativa, and is described in most of the larger textbooks on dermatology. Many of the patients are delicate children, and debility seems to be an exciting or predisposing cause.

The condition may follow a clinical course marked by exacerbations and remissions. Treatment consists in constitutional remedies to correct any deviations from the normal, such as anemia and marked constitutional debility. High vitamin feedings and the use of antianemic substances are indicated. Local irritation should be reduced to a minimum, and the use of a bland diet and soothing astringent lotions and mouth washes is in order. Serious sequelae, as a rule, are not noted in this condition.

## LEUKONYCHIA AND ONYCHOLYSIS

*To the Editor:*—A man, aged 37, 6 feet (183 cm.) tall, weighing 195 pounds (88.5 Kg.), married, a salesman, began to notice a gradual whitening and then a cracking of the fingernails five years ago, beginning at the edge of the cuticle. A number of such white cracking areas gradually appeared on the nail. The nail gradually loosened up. The nail becomes hard and brittle, and striking the nail against anything solid breaks it. The only treatment given, to my knowledge, was capsules of vitamin B. Please give me what information you can regarding the diagnosis and treatment. Please omit name.

M.D., Wisconsin.

*ANSWER:*—From the description the patient apparently has a combination of leukonychia and onycholysis. The cause of these conditions is obscure. The separation and loss of the nail, together with increased fragility, sometimes occurs as a symptomatic process in psoriasis, eczema and syphilis. Idiopathic neurotic cases have also been described. In some of these patients there is associated hyperhidrosis. The possible contributory factor of external irritants in the course of occupational contact must be borne in mind.

The response to treatment in these cases is quite variable. Protection of the nail from trauma, the application of bland oils and ointments, and the use of a high vitamin diet fortified by the administration of vitamins A, B and D is of value. Dicalcium phosphate by mouth is also a useful adjunct to therapy.

## NEURITIS DURING PREGNANCY

*To the Editor:*—A woman, aged 35, in her first pregnancy, had pyelitis two years ago and one year ago. The urine has been normal since conception in April. In May there was numbness over both lateral cutaneous nerves of the thigh. In June an occasional pain was felt in the nerves, and numbness was continuous. By July the pain was considerable, requiring acetylsalicylic acid. There has been no change in the area of the numbness or the pain. The urine, blood pressure, teeth, tonsils, bowels, Wassermann reaction, blood sugar, gain in weight, habits and attitude are all normal. In August, bromides were required for rest at night. Please omit name.

M.D., Texas.

*ANSWER:*—Pain over the distribution of both lateral cutaneous nerves during pregnancy is extremely unusual. The most common site for root pains in pregnancy is in the distribution of the sciatic nerves. It is possible that the gravid uterus by pressure upward has involved the lateral cutaneous nerves as it passes through a tunnel in the inguinal fascia; or the wearing of a special corset during pregnancy or for that matter the change in posture, although a corset worn before is used, may shift pressure on these nerves, causing pain on the lateral thigh surfaces, known to neurologists as meralgia paraesthetica. The treatment should consist of removing all tight constriction from the inguinal region. In any case, relief is to be expected on termination of the pregnancy.

## DERMATOMYOSITIS

*To the Editor:*—A clerk, single, aged 21, had pain and tenderness in the right thigh and in the back of the left knee. He stated that he had four or five previous attacks of this nature in the past few years. They had always followed a toothache and his dentist did not care to remove the offending tooth for some time because of orthodontic work that was being done. The patient's temperature was 102.2 F. and pulse 84. His right lower first molar was carious. The rest of the physical examination was without significance except in the lower extremities. The right sartorius muscle was clearly defined by redness, swelling, heat, tenderness and induration. A similar condition was observed for the left popliteus muscle. There was no evidence of fluctuation. Conservative treatment—rest, fluids, analgesics and hot applications—was prescribed. In two days the symptoms had abated but there was still some induration at the site of these muscles. By the fourth day even this had subsided. I would like to ask whether a diagnosis of acute suppurative (aborted) myositis is justified. If not, what are the diagnostic possibilities? How common is the condition in this country? What further treatment should the patient have besides the removal of the apparently offending tooth? If published, please omit name.

M.D., New York.

*ANSWER:*—This is an unusual case and might be a dermatomyositis. The condition is uncommon in this country, most of the cases of infectious myositis having originated in Europe. The local treatment would be symptomatic. There is no question that the tooth should be removed and, if pus is found, a vaccine made in case it is desired to administer it.

## TREATMENT OF PAGET'S DISEASE

*To the Editor:*—I have a female patient, aged 52, whose illness has been diagnosed by several competent clinicians as nonsyphilitic Paget's disease of the bones, which at present involves the cranium, pelvic bones, legs and one arm. Each physician has discouraged the patient as to treatment and prognosis. She has appealed to me for relief of her severe headaches and leg pains. Please inform me of the latest developments in this disease, if any, and the best treatment for the relief of her pains. Please omit name.

M.D., Wisconsin.

*ANSWER:*—The treatment for Paget's disease of the bone is still highly unsatisfactory except for orthopedic measures. The administration of high doses of viosterol together with daily intravenous injections of calcium has been recommended. For palliative purposes of relief of the intolerable pain, in some instances irradiation with small amounts of x-rays or radium to the involved area may be successful.

## PIGMENTATION OF VACCINATION SCAR

*To the Editor:*—I have a child, 7 years of age, who was vaccinated ten months ago for smallpox by another physician. A hematoma formed at the site of the vaccination and was surgically removed in May 1936. The vaccination scar is entirely healed but there is still considerable discoloration of the skin about an inch in diameter at the site of an old hematoma. The child's mother is much concerned as to whether this discoloration will ever entirely disappear. Please omit name.

M.D., Wyoming.

*ANSWER:*—The discoloration and pigmentation of the skin at the vaccination scar is the result of pigment deposited at the site. The pigment in this instance is most probably derived from the blood (an old hematoma), in which case it contains iron and is situated in the dermis. There may also be asso-

bone with a sharp pointed instrument such as an antrum trocar obviously will further injure the already traumatized mucous membrane within the antrum and should not be used for elevating the bone. A solid urethral sound is better.

J. J. HORTON, M.D., Memphis, Tenn.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### PREGNANCY AFTER TUBERCULOSIS

*To the Editor:*—What is the present best opinion as to dangers of pregnancy in a 40 year old American born, one-eighth colored blood, who had one child sixteen years ago and developed active pulmonary tuberculosis five years ago for which she spent two years in a state sanatorium, where extensive left thoracoplasty was done, resulting in apparently completely arresting the disease? The patient returned home two years ago and has been observed monthly since, negatively as to a pulmonary condition. Is an early abortion definitely indicated? If pregnancy proceeds, what are the chances of lighting up the pulmonary condition? At what stage of pregnancy is it most likely to reappear, if it does at all? If she goes to term is a long labor more or less dangerous than operative intervention in the second stage? If any operative intervention becomes essential, what type of anesthesia is least dangerous? M.D., Massachusetts.

**ANSWER.**—Pregnancy is usually considered safe for the patient who has had pulmonary tuberculosis provided the lesion is healed and has remained so for a period of two years or longer, corroborated by repeated x-ray examinations. From the information given, the prognosis as regards this pregnancy should be good, since one assumes that the first pregnancy was not complicated by toxemia or difficult labor. The age factor of itself is of little moment. Such a patient, however, requires careful watching throughout the pregnancy and frequent x-ray examinations to make certain that no new infection has developed.

An early abortion is not indicated unless it is demonstrated that a fresh infection has developed in the other lung or the healed lesion has become activated. On the other hand, if nephritis or heart disease should complicate the picture or if hyperemesis is present, the uterus should be emptied early. As to the possibilities of lighting up the pulmonary condition, little can be said one way or the other. The chances are all dependent on whether or not the lesion has been completely healed. If a lighting up of the pulmonary condition does occur, it is most likely to occur in the latter months of pregnancy when the splinting of the diaphragm induces a costal type of breathing and the respiratory rate becomes increased. If activation does take place it is most likely to manifest itself as a tuberculous pneumonia.

More frequently, however, activation occurs in the puerperium, owing perhaps to the effect of the labor, the straining and increased blood pressure being sufficient to break down walled off areas and thus liberate many free organisms. If the patient goes to term she should certainly be spared the exhausting effects of a long labor with the resulting depletion in the powers of resistance. Therefore, if a long labor is anticipated, one should seriously consider elective laparotomycelotomy under local infiltration anesthesia, combining with this operation some form of sterilizing procedure. If active infection is present it might be well to do a Porro operation, removing a potentially tuberculous placental site.

When the first stage is likely to be normal, the analgesic of choice would logically be morphine, avoiding the newer barbiturates. Voluntary bearing down efforts should not be permitted in the second stage, since the increased work throws too much strain on the lungs. The treatment of the second stage should resemble that of the cardiac patient; i. e., an operative delivery provided the patient does not quickly and effortlessly deliver herself.

The least dangerous type of anesthesia is obviously one that will not affect the respiratory system. Therefore, some form of local anesthesia is indicated. Thus, for a simple outlet forceps infiltration anesthesia or infiltration plus pudendal block is satisfactory. When it is necessary to do a major operative delivery, such as a midforceps, the parasacral technic may be used and will usually give adequate anesthesia and is least dangerous.

### BLEEDING AT THE MENOPAUSE

*To the Editor:*—A woman, aged 51, in whom menstruation began at 14 and was regular every twenty-eight days, with a profuse flow of from nine to ten days, went through the menopause at 47 with irregular menstruation for two and one-half years. She was treated by a physician, who stopped the bleeding in six months. She came to my office complaining of profuse bleeding after nine months' cessation, weakness, headache and slight lumbar pain. At the first period, February 23, she bled for ten days. The second period started March 23 and she is still flowing after sixteen days. Her weight is 200 pounds (91 Kg.). The blood pressure is 144 systolic, 90 diastolic. There is tenderness to pressure over the uterus and the left tube. The cervix is clear. The flow is mixed with clots. What is the diagnosis? Please outline therapeutic measures. Kindly omit name. M.D., Illinois.

**ANSWER.**—The only certain way to make a diagnosis in this case is to perform a curettement and this should be done without any delay. A woman who is 51 years of age and begins to bleed profusely from the uterus after having stopped menstruating for nine months should be looked on as having a carcinoma of the uterus until this diagnosis is ruled out. It is by no means true that all women with such a history have cancer of the uterus, but every physician should think of this diagnosis first and waste no time in performing a diagnostic curettement or biopsy of the cervix or both. If the uterine endometrium fails to reveal a carcinoma, a benign endocrine basis may be assumed for the bleeding. However, this diagnosis should not be made until a careful bimanual examination has been made to rule out an ovarian tumor, such as a granulosa cell tumor. If there is no malignant condition present in the cervix or the body of the uterus the bleeding can be stopped by the application of radium within the uterine cavity or, by high voltage roentgen therapy. If cancer is present in the uterus a total hysterectomy may be performed with preoperative or postoperative radiation therapy, or the treatment may consist entirely of irradiation.

### INDUSTRIAL DERMATITIS IN CONDUIT FACTORY

*To the Editor:*—Workers in a line manufacturing company near here have been having considerable trouble with a dermatitis limited to the face. These men work in a yard where conduits are stacked. Contact with the conduits is not necessary to produce the eruption, and they are able to handle them without danger of the dermatitis developing on the hands. The workers believe that the wind blowing off the conduits toward them carries some chemical that causes the dermatitis. Six out of the ten yard workers are afflicted in this manner. Workers inside the plant engaged in the manufacturing of the conduits have no trouble, but when they go into the yard they too develop the eruption. The yard workers, on the other hand, when transferred to the factory have no trouble. The conduits are made in the following manner: Pulp and water are mixed together, placed on a form and allowed to dry. They are then dipped in pitch again, allowed to dry and then stacked in the yard. The chemical components of the pitch solution are not known and the manufacturer won't tell. Apparently when the pitch dries some irritating chemical is released which is the irritant. We have ruled out ragweed, ivy, and so on. We believe that it is due to some chemical in the pitch and I wondered whether you have any knowledge as to what the irritant might be and some method to combat it. H. J. FARRELL, M.D., Milwaukee.

**ANSWER.**—Only a speculative reply can be made at this time, owing to the absence of salient information in the data submitted. The term "pitch" is loosely applied to rosin, bituminous and petroleum still residues, asphalt, creosotes, and conceivably water gas tar and coal tar. Since the high temperatures necessary to reduce some of these substances to a limpid state suitable for application to paper would damage the paper, it is presumed that this pitch is applied in chemical solution or suspension. The solvent employed for this purpose might be any one or a combination of several. The most likely is some petroleum derivative on the order of naphtha. Additional possible constituents among others are solvent naphtha, carbon bisulfide, chlorinated hydrocarbons and crude light oils. Any of the agents mentioned may be the source of a dermatitis following contact either indoors or outdoors, but more readily prior to drying. The diagnostic difficulty lies in the statement that the dermatitis arises only among workers employed outdoors handling the dried conduits and in the limitation of the dermatitis to the face, whereas the hands coming directly in contact with the conduits are consistently free. It is well known that certain chemicals respond to the action of chemical rays in the sunlight by the production of new or augmented irritants. Turpentine may be presented as an example. Freshly distilled gum spirit turpentine is relatively nonirritating to the skin. After it has been exposed to the sunlight, irritant properties quickly are increased. This is equally true when air is bubbled through fresh turpentine. A related phenomenon may account for the occurrence of a dermatitis in these yard workers but will not explain the freedom from involvement of the skin

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, March 6, page 832.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country on April 17. *Oral examinations for Group A and B applicants* will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7 and Chicago, Oct. 9. *All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Philadelphia, June 12. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Philadelphia, June 2. *To be considered for this meeting, applications must be in the hands of the Secretary before April 2.* Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Written examinations* will be held in various cities in the United States, April 3. *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicolet Ave., Minneapolis.

### Idaho October Examination

Hon. J. L. Balderston, commissioner of law enforcement, reports the oral and written examination held by the Idaho State Medical Examining Board at Boise, Oct. 6-7, 1936. The examination covered 22 subjects and included 135 questions. An average of 75 per cent was required to pass. Nine candidates were examined, all of whom passed. Nineteen physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1936)		83
Loyola University School of Medicine.....	(1935)		87
Northwestern University Medical School.....	(1936)	86, 88

\* License withheld pending completion of internship.  
† Verification of graduation in process.

### Arizona October Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, Oct. 6-7, 1936. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventeen candidates were examined, 12 of whom passed and 5 failed. Sixteen physicians were licensed by reciprocity and 4 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine.....	(1935)		77.3
George Washington University School of Medicine.....	(1934)		85.9
Northwestern University Medical School.....	(1936)		77.9

The question rules out most of the common causes for dyspnea. Inspiratory dyspnea, or difficulty in getting air into the lungs, occurs most commonly as a result of obstruction of the trachea or larynx by a foreign body or tumor, an aneurysm of the aorta or subclavian artery, laryngeal spasm, paralysis of the posterior crico-arytenoid muscle, edema of the lung, lung collapse, or massive pleural or pericardial effusion. Most of these seem unlikely in the case under discussion.

The question states that at the first examination the patient was found to have a pulse of 165. It is assumed that this finding was not constantly present together with the dyspnea. A pulse rate of 165 could in itself produce dyspnea, and an abnormal rhythm, such as paroxysmal tachycardia, could easily bring about such a rate. If this assumption is correct, cardiac dyspnea does not seem likely. It is assumed that renal disease does not exist, although the question does not so state. Nor does obstructive dyspnea seem reasonable. The only reasonable explanation seems to lie in a central nervous system or constitutional cause.

A brain tumor irritating the respiratory center seems unlikely because of the lack of further signs of tumor. This is worth consideration, however. The nystagmus and disk pallor suggest a multiple sclerosis, but this condition is not usually associated with dyspnea. Postencephalitic parkinsonism is characterized by dyspnea, but this patient shows no symptom other than the dyspnea.

The convulsive seizure raises the question of parathyroid disease. Did the seizure resemble parathyroid tetany? Tetany is often accompanied by laryngeal spasm, which would produce dyspnea. This possibility should be investigated.

Did the negative Wassermann and Kahn reaction include the spinal fluid or only the blood?

Lastly a functional disturbance must be considered. A neurosis may produce dyspnea and the unexplained dysphagia is highly suggestive. An anxiety neurosis will cause a pulse of 165. It is unwise, and even dangerous at times, to assume that a neurosis is responsible for such a condition without working out all possible organic causes.

#### EFFECTS OF TRAUMA ON HEART

To the Editor:—About four months ago I first saw a man, aged 52, who was complaining of pains in the lower part of the chest and the upper part of the abdomen, anorexia, nausea, loss of weight and constipation. The patient was in perfect health up until one month before my first visit, when he was struck by a radiator casing, which fell from the second story of a building and landed on the lower part of his chest and abdomen. From the day of the accident until his death five months later his course was progressively downward, with the chief complaints being pains in the epigastrium, nausea, anorexia, constipation and insomnia and the loss of 60 pounds (27 Kg.). X-ray examination of the chest after the accident revealed no fractures. Examination of the patient one month after the accident revealed his heart slightly enlarged with the tones of fair quality. The liver was enlarged to four fingerbreadths below the costal arch (there was a history of alcoholism) and it had several irregular masses on the surface. There was tenderness in the epigastrium. The patient finally died of heart failure. Complete x-ray examination of the gastro-intestinal tract, one month before death, revealed no evidence of cancer. In view of the fact that the patient was in perfect health before his injury and had a downward course until death following the accident, is it possible in any way to make some connection between cause and effect in relation to the injury and some internal injuries? Please also give me references as to where I can find similar cases of traumatic origin. Please do not publish name.

M.D., New York.

ANSWER.—With a history of perfect health before the injury and progressive weakness until death five months later apparently from cardiac changes, one must consider traumatic injury to the heart.

The history of epigastric pain, loss of appetite and weight with enlargement of the liver would suggest some abdominal change such as cirrhosis of the liver or chronic passive hyperemia. The nodular feeling would suggest a malignant condition such as metastases from a carcinoma of the body or tail of the pancreas. This and other pathologic changes in the abdominal viscera of traumatic or other origin cannot be excluded. Certainly without a postmortem examination no definite diagnosis can be made.

Bright and Beck (Nonpenetrating Wounds of the Heart, *Am. Heart J.* 10:293 [Feb.] 1935), in reviewing cases in the literature in which traumatic injury to the heart was survived, found that in practically all instances the symptoms developed immediately and persisted until recovery. In one instance the symptoms disappeared and the patient resumed work but died suddenly ten months after the injury. From experimental observations Beck (Contusions of the Heart, *THE JOURNAL*, Jan. 12, 1935, p. 109) believed that the onset of cardiac symp-

toms may be somewhat delayed in certain cases, although further data are necessary. Usually after experimental trauma to the heart there was a tachycardia but occasionally it slowed later. The electrocardiographic changes may resemble coronary disease and ventricular fibrillation.

The Kahns (Cardiovascular Lesions Following Injury to Chest, *Am. Int. Med.* 2:1013 [April] 1929) described the development of symptoms which is necessary to place the responsibility of cardiac damage on the injury from an industrial or compensation standpoint.

Briefly these constitute: An injury to a healthy person who was able to pursue his occupation previously. The development of cardiovascular symptoms that would indicate aggravation of an existing lesion or damage to a normal heart. The time that elapses between the injury and pain, dyspnea, and rapid or irregular pulse must be short.

Schlomka (Die akute traumatische Herzdilatation, *Verhandl. d. Deutsche gessellsch. f. inn. Med.* 45:220, 1933) found that definite changes of the heart could be produced by trauma experimentally as evidenced by electrocardiography with changes in the rate and regularity of the pulse. There was an early increased arterial and especially venous pressure, but with more extensive trauma there developed dilatation of the heart, symptoms of shock and cerebral anemia. Experimental work indicated that there may be permanent damage to the heart muscle from severe trauma, without rupture.

#### STAINING FROZEN SECTIONS FOR TUBERCLE BACILLI

To the Editor:—I would appreciate very much any information as to the most reliable method of staining frozen sections for the identification of the tubercle bacillus.

R. F. MILLER, M.D., Glasgow, Mont.

ANSWER.—H. J. Corper (Methods of Staining Tubercle Bacilli, *J. Lab. & Clin. Med.* 11:503 [March] 1926) studied a large variety of staining methods for tubercle bacilli, from which he concluded that for practical purposes the simple steaming carbolfuchsin (Ziehl-Neelsen) method for staining tubercle bacilli or one of its modifications is to be recommended and suggested (A Control Method in Staining Smears for Tubercle Bacilli, *Arch. Path. & Lab. Med.* 1:93 [Jan.] 1926) that the student practice the technic of staining tubercle bacilli on known positive tuberculous material for control. The carbolfuchsin technic is adaptable to all kinds of pathologic specimens containing acid-fast bacilli when appropriately used. Sections require a little longer staining than smears of pus or sputum. When chemical fixative is present, E. G. D. Murray (*J. Path. & Bact.* 27:118 [Jan.] 1924) removes formaldehyde by means of ammonia before staining frozen sections; Marbais (*Schweiz. med. Wchnschr.* 62:377 [April 16] 1932) points out that iodine inhibits the acid-fast reaction; this should be removed preferably by appropriate neutralizing or washing before staining with the fuchsin. Basic stains as a rule are suitable for staining, a standardized basic fuchsin being preferable. Usually the removal of interfering chemicals will make frozen sections adaptable to staining with carbolfuchsin for acid-fast bacilli, but Emma S. Moss (*U. S. Vet. Bur. M. Bull.* 6:590 [July] 1930) presents the following method for staining tissues containing tubercle bacilli by the frozen section technic:

Fixation over night in 4 per cent solution of formaldehyde or boiling a few minutes in 40 per cent solution of formaldehyde to which a few drops of acetic acid have been added.

Wash in tap water to remove fixing solution.

Freeze and cut sections.

Select a thin section for staining and float onto a slide with the aid of a capillary pipet, removing excess of water.

Flood section with 40 per cent solution of formaldehyde for eight minutes.

Remove and flood with water several times.

Slightly overstain with Harris's hematoxylin about thirty seconds.

Flood with water several times, removing the excess.

Stain with Ziehl-Neelsen carbolfuchsin cold for eight minutes.

Remove stain and flood with 70 per cent alcohol or water.

Decolorize to a faint pink with 10 per cent citric acid in 70 per cent alcohol.

Flood with water several times.

Neutralize in 0.5 per cent lithium carbonate.

Flood with water several times.

Dehydrate in 95 per cent alcohol.

Completely dehydrate and clear in terpineol (absolute alcohol may be used).

Completely clear in carbolxylene (phenol 30 parts, xylene 70 parts).

Wash with xylene and mount in Canada balsam.

This method has proved satisfactory with human necropsy material and surgical materials, as well as animal materials. It is possible to cut, stain and examine the tissues within thirty minutes and the sections may be filed as permanent mounts.

cent of the sum of the sugars plus the total acid hydrolyzable carbohydrate from the alcohol insoluble residue, a considerable part of which is known to be pentosans and not available for human beings.

In these studies of McCance and Widdowson the unavailable carbohydrate for almonds is reported as 74 per cent, for Brazil nuts 78, for peanuts 52 and for walnuts (*Juglans regia*) 82. There are too few analyses of nuts available to make any satisfactory comparisons.

One section of the report is devoted to changes in composition brought about by cooking processes, as steaming and pressure cooking, boiling in water, baking, and cooking in fat (frying and roasting). Many of the changes are expressed graphically. The leaching action of the surrounding water was found to account for nearly all the losses of minerals and sugars incurred on boiling, the extent of loss varying directly with time of cooking and inversely with the size of the pieces; the volume of the cooking water did not greatly affect the losses. The addition of alkali when green vegetables are boiled also had little effect on the mineral losses. Practically, the authors point out, the waste incurred by throwing away the water in which vegetables have been boiled is surprisingly small, conservation of the water not usually serving to increase the total calcium, phosphorus and iron in a mixed diet by more than 3 per cent.

An excellent bibliography is appended.

**So You're Going to a Psychiatrist.** By Elizabeth I. Adamson, M.D. Cloth. Price, \$2.50. Pp. 263. New York: Thomas Y. Crowell Company, 1936.

Many attempts have been made to explain to interested lay persons the meaning of psychiatry and the purposes of psychotherapy. Most works are patently propaganda for so-called mental hygiene or the "Meyerian Legend." These books are usually simple in content and confusing in effect. Dr. Adamson has written an intelligent work concerning psychiatry from the psychoanalytic point of view. Her data are correct and well expressed. However, the material could be understood by few neurotic patients, owing first to their emotional blocking and secondly to the fact that psychoanalytic psychiatry requires considerable intelligence for its understanding. Why it is necessary to burden the lay mind, neurotic or potentially neurotic, with information about the theory with which the physician may work is a puzzle. In dealing with other organ systems it is unnecessary for the patient to know the physiology and pathology before undergoing treatment. Certainly the methods of treatment of, let us say, bowel distress differ as widely in theory and practice as do the methods of treatment of the neuroses. Actually the preliminary theoretical knowledge, usually garbled by the popular writer and profoundly misunderstood by the lay reader, serves to make psychotherapy more difficult. Dr. Adamson's book is one of the best popular works explaining psychoanalysis for the purpose of general information of intelligent persons but it should by no means be put into the hands of a patient who plans to consult a psychiatrist.

**The Endocrine Organs in Health and Disease, with an Historical Review.** By Sir Humphry Dary Rolleston, G.C.V.O., K.C.B., M.D., Honorary Fellow of St. John's College, Cambridge. Cloth. Price, \$13. Pp. 521, with 45 illustrations. New York & London: Oxford University Press, 1936.

The material included in this book is largely the result of a series of lectures on the history of the endocrine organs given by Rolleston before the Royal College of Physicians in London in 1933 and 1934. The Fitzpatrick lectures, as they are called, include four discussions but the supplemental material in the present book makes up a volume of fourteen chapters, including not only a history of endocrinology from the earliest times but also, through the historical approach, a fine summary of our present knowledge of this subject. Moreover, there are fine photographic plates of all the great contributors to this field and extensive citations from a vast bibliography indicating the scope of the author's reading. The biographic sketches throughout are well written and separated from the general text by a change in typography. This is a fundamental reference work in the field which it concerns and a valuable addition to any medical library. The index is so comprehensive and well organized that it deserves special mention.

**Pratique médico-chirurgicale.** Publiée sous la direction de A. Courvaire, A. Lemierre, et Ch. Lenormant, professeurs à la Faculté de médecine de Paris. Secrétaire général, André Ravina. Tome IX: Supplément. Third edition. Half-cloth. Price, 165 francs. Pp. 960, with 276 illustrations. Paris: Masson & Cie, 1936.

This supplement to the eight volume series of *Pratique médico-chirurgicale* (1931) is intended to cover the advances of the last six years. This is done in most instances by short chapters but in some cases the entire article has been rewritten. The editors have exercised all possible care to avoid unproved theories or forms of practice merely because they are new and before their practical utility has become evaluated. Most prominent throughout the volume, the material of which is arranged alphabetically, are the chapters on advances in roentgenography of the various organs. Climatopathology and meteoropathology are treated rather comprehensively. There is so much in this "supplement" that is new and useful in the practice of medicine and surgery that the book may be recommended even to those French reading physicians as a review of medical progress, as the French see it, who do not possess the other volumes of this system of medical and surgical practice.

**A Century of Medicine in San Antonio: The Story of Medicine in Bexar County, Texas.** By Pat Ireland Nixon, M.D. Cloth. Price, \$4. Pp. 405, with 32 illustrations. San Antonio, Texas: The Author, 1936.

This volume was developed by its author primarily because of his own interest in the community in which he has for so many years resided. Much of the material that is contained in the book has already been presented in various ways to the physicians of San Antonio. The profits from this volume, if any, are to accrue to the library of the county medical society.

The territory concerned is one of the most romantic in the United States. Its history is full of lively incidents and the author of this volume has made available a great deal of this material in connection with the medical history of Bexar County. It will be remembered that San Antonio is the home of the Alamo and the volume logically begins with the period before the Alamo and then traces history chronologically since that period. The material is supplemented by anecdotes and extracts from diaries and also by some excellent pictures, presumably from the author's private collections.

It relates the purchase of a home for the medical society and the progress of medical organization and concludes with a forecast for the future. As a contribution to American medical history, this book represents the best type of personal investigation.

**The Principles of Bacteriology and Immunity.** By W. W. C. Topley, M.A., M.D., M.Sc., Professor of Bacteriology and Immunology, University of London, and G. S. Wilson, M.D., F.R.C.P., D.P.H., Professor of Bacteriology as Applied to Hygiene, University of London, London School of Hygiene and Tropical Medicine. Second edition. Cloth. Price, \$12. Pp. 1,645, with 276 illustrations. Baltimore: William Wood & Company, 1936.

This work was first published in 1929 and reprinted in 1931, 1932 and 1934. The new edition has witnessed extensive advances in the field of bacteriology and immunity, which the authors have observed and duly incorporated in their text. They call attention to the fact that they deal with infective diseases of animals rather more fully than in most medical works. Originally published in two volumes, the material is now published in a single volume which is somewhat unwieldy, but apparently the majority of the critics of the first edition felt that a one volume work was more usable than a two volume work. The book is extensive, profound, well annotated and unquestionably a useful textbook in the field that it concerns.

**Sammlung psychiatrischer und neurologischer Einzeldarstellungen.** Herausgegeben von Prof. Dr. A. Bostroem und Prof. Dr. J. Lange. Band XI: Die defektschizophrenen Krankheitsbilder: Ihre Einteilung in zwei klinisch und erblich verschiedene Gruppen und in Unterformen vom Charakter der Systemkrankheiten. Von K. Leonhard, Oberarzt der Nervenkrankheiten. M. Paper. Price, 8.70 marks. Pp. 131. Leipzig: Georg Thieme, 1936.

The author discusses the classification of schizophrenic forms ending with defect. He brings numerous clinical descriptions to substantiate an elaborate classification of defects. His point of view is essentially "biologic" in that he, like most German psychiatrists today, attempts to separate genetically linked groups within clinical entities. The work is purely descriptive and classificatory. It bears the stamp of the Kleist concept of organic system defect in the psychoses and ignores the recent advances of psychologic studies of schizophrenia.

siderable experience with this disease that remarkably prompt recoveries follow the intramuscular administration of the nucleotides. From a study of the myelocytic response, which in all essential respects parallels the reticulocyte response during recovery from anemia, it is difficult to escape a causal relationship between nucleotide therapy and renewed bone marrow activity. The experimental studies in animals strongly affirm the specificity of the granulopoietic stimulus inherent in the nucleotides. Intramuscular liver therapy may also be employed. Great care must be exercised in the differential diagnosis of leukopenic states to avoid attributing failures unjustly to treatment when the underlying mechanism may really be misjudged.

#### OVARIAN DYSFUNCTION TOGETHER WITH EMOTIONAL DISTURBANCE

*To the Editor:*—I am caring for a woman, aged 23, whose weight is 118 pounds (53.5 Kg.). She complains of weakness, infrequent sparse menstrual periods and peculiar epileptiform seizures. The seizures appear mostly during the night but occasionally appear in the day time preceding meals or following meals when she has had noodles or spaghetti. Those seizures which appear during the day are not preceded by an aura. She is aware of the fact that she has them and they usually do not last more than two or three minutes. During the time she is so affected there are perspiration, marked tremor, and inability to speak or breathe properly. This entire train of symptoms followed an appendectomy for acute appendicitis in 1932. They have been successively diagnosed as hysteria, nervous shock and petit mal epilepsy. Owing to the appearance of these seizures during the night, when she was hungry, or after meals that contained little carbohydrate (when noodles were substituted for potatoes in meals) a provisional diagnosis of spontaneous hypoglycemia was made and verified by blood sugar determinations. Fasting blood sugar was 60 mg. per hundred cubic centimeters. The dextrose tolerance test after 100 Gm. of dextrose was: thirty minutes later, 80 mg.; sixty minutes later, 100 mg.; two hours later, 70 mg.; four hours later, 70 mg. I should like to know just how this case should be treated. The physical examination is negative; other laboratory procedures, such as the Wassermann test, blood count and urinalysis, give normal results. The patient would rather not be subjected to exploratory operation for examination of the pancreas.

M.D., New York.

*ANSWER:*—The description of the seizures and the history of the case seem to argue against a diagnosis of petit mal epilepsy. It seems much more likely that this condition is in the nature of some emotional or functional disturbance associated with the ovarian dysfunction. There is no particular reason why hypoglycemia should follow a meal of noodles or spaghetti. These foods are made of wheat, which is 76 per cent carbohydrate. Therefore, unless the patient is allergic to wheat there is no reason why the disturbance should follow the ingestion of these foods. It would be advisable to repeat the dextrose tolerance tests. There are individuals who may have low fasting blood sugars, and there have been several cases of hyperinsulinism or hypoglycemia reported which on further checkup have been found to have a normal dextrose tolerance. In a report on this test there should be included the amount of dextrose given and the patient's weight and height at the time. Before extensive treatment is instituted there should certainly be at least one additional dextrose tolerance test. The blood sugar determinations must be done by a competent technician. In case of definite hypoglycemia, dextrose may be given in any of the desired forms every two hours between meals. A large amount should be taken before going to bed and immediately on arising. Additional dextrose must be provided before or during any severe muscular exertion.

#### SODIUM CHLORIDE INJECTIONS FOR VASCULAR OCCLUSION IN LIMBS

*To the Editor:*—Please give me instructions for the treatment of arterial occlusion in the lower extremities. It is not extreme and there is no gangrene; marked intermittent claudication occurs on walking any distance. I should like to try intravenous concentrated sodium chloride but want your recommendations and also the amount, frequency of use and concentration found best for intravenous use. Is sodium citrate better? Please omit name if published.

M.D., Wisconsin.

*ANSWER:*—If the patient is not over 60 years of age and if his heart and kidneys are sound, treatment by means of intravenous injections of sodium chloride solution offers a safe means of improving the circulation in the lower extremities. Sodium chloride is better than sodium citrate because it is less toxic. Five per cent sodium chloride solution is made up in freshly distilled water and immediately sterilized. If this precaution is not followed, bacteria will grow in the distilled water and later sterilization will result in a solution that contains foreign protein matter. If any chills or fever reaction follows the treatment, it is an indication that the solution has been improperly prepared. For the first treatment 150 cc. is given, and all subsequent injections are of 300 cc. Treatments are given

three times a week on alternate days for a few months, and the frequency of treatment is gradually reduced as the patient improves. The injections are given in the vein of the arm with the patient lying down and should take about ten minutes. Absolute cessation of smoking must be enforced. The feet should be protected from injury, and minor surgery of any kind should be avoided.

#### PERSISTENT RHEUMATIC INFECTION WITH HEART COMPLICATIONS

*To the Editor:*—A 17 year old, well developed, farmer lad during a cold in January developed pain over the left anterior portion of the chest, a continuous pricking sensation. There was a fever of 99 F., pulse 106, and blood pressure 155 systolic, 100 diastolic. Two weeks later during snow-blocked roads a brother gave me these symptoms: fever, sweating, joint pains, pain over the heart, tachycardia and palpitation at times and nosebleeds. My diagnosis was rheumatic fever with endocarditis and myocarditis. The urine was negative microscopically and macroscopically. I have treated him with large doses of sodium salicylate continuously up to the present time. In April an abscessed tooth was extracted and in May I removed his tonsils under local anesthesia. At the present time examination shows damage of the mitral valve (regurgitation and some stenosis). The systolic blood pressure varies between 130 and 140; the urine is normal; temperature is 98.8; some sweating occurs. He feels well, eats well and sleeps well. It is now about six and one-half months since the first signs of disease appeared and his pulse still remains between 120 and 130, of good quality and regular. There is no ankle edema, no cough, the heart is not enlarged and I find no evidence of pericardial involvement. What causes the continued rapid pulse or what hints could you suggest toward further investigation in this case? Please omit name.

M.D., Wisconsin.

*ANSWER:*—It seems quite certain that the patient is still suffering from acute rheumatic infection, even though the joint symptoms have subsided. His slight elevation of temperature, sweating and tachycardia all indicate persistent activity of the rheumatic process, which, it is known, can continue for many months or even a year or two, especially in childhood. There is undoubtedly rheumatic myocardial involvement, probably with some dilatation of the heart to account for the murmur at the cardiac apex suggestive of mitral stenosis, even though the heart does not seem to be enlarged. If he has had previous rheumatism he may actually have mitral stenosis, but until the present infection subsides it is impossible to say how much valvular deformity he now has, for dilatation of the heart in such a young person will produce the same murmurs caused by mitral valve deformity.

The patient should have further observation for persistent infection, a four hourly temperature chart should be kept, leukocyte counts should be made once or twice a week, and the blood sedimentation rate should be determined. If he continues to feel well and these tests are all negative, the infection may be considered to have subsided. Until such evidence is obtained, however, he should continue with rest treatment. No drugs are needed; in fact, the omission of salicylates may reveal more definite fever (masked recently by the drug). He should be afebrile for a fortnight at least while not on salicylate therapy before he is allowed out of bed.

#### OPTIMAL PERIOD OF FERTILITY

*To the Editor:*—A woman, aged 25, sterile of undetermined cause, desires pregnancy. She is receiving medical treatment and tubal infatation. When is the optimal time for conception? She has a twenty-eight day cycle, menstruation lasting six days. When do the "sterile" periods exist and are they absolute? Please omit name.

M.D., Canada.

*ANSWER:*—The sterile days in a twenty-eight day cycle are composed of the first nine days of the cycle (the count beginning with the first traces of the flow) and the last eleven days of the cycle. The division of time would be expressed by 9-8-11, indicating nine days of sterility, eight days of fertility and eleven days of sterility. Within the fertile period the optimal time for conception is the fourteenth day of the cycle, being the day on which ovulation occurs in a twenty-eight day cycle.

The menstrual histories of 2,000 women accurately recorded for periods ranging from eight months to several years and contained in an article published in *THE JOURNAL* Oct. 19, 1935, page 1241, indicate that no woman has an invariable cycle. Variations of one, two or more days will always be found in a written menstrual record of eight months or more. The optimal time for conception in a twenty-eight day cycle, as well as in a cycle of any other type, is shown graphically in chart 1 of this article.

Absolutism in physiologic laws is nonexistent. Chart 3 in the article referred to indicates that normal, healthy women, with regular menstrual histories (i. e., with variations of not more than eight or ten days) can employ the sterile periods with satisfaction.

did express an opinion contrary to that he gave at the first trial was not questioned. Except for his testimony, the evidence went no further than to indicate that, while earlier treatment might have been beneficial, it was a matter of speculation as to whether the failure to give it was the cause of the plaintiff's subsequent condition. This was a vital question in the case and it was within the province of the court to point out its importance and specifically to call to the attention of the jury the change in the testimony of the witness as affecting the weight which they should give to his changed opinion.

The plaintiff complained because the trial court failed specifically to charge the jury that although a physician is ordinarily not responsible for an error of judgment he cannot adopt a course of treatment which would be a breach of his duty to use due care, and that even though he has used his best judgment he may still be found guilty of malpractice if he has failed to perform one of the duties which he owes to his patient. The trial court repeatedly charged the jury that it was the duty of the defendant to exercise due care and skill required of a specialist in the field of obstetrics, and the charge made it abundantly clear that he would be absolved from a bona fide error in judgment only in case he exercised such care and skill. After reviewing the whole case, the Supreme Court of Errors was of the opinion that no prejudicial error was evidenced by the record and the judgment of the trial court for the defendant was affirmed.—*Green v. Stone (Conn.)*, 185 A. 72.

**Optometry: Corporate Practice of Optometry Illegal in Ohio.**—The Buhl Optical Company, a Delaware corporation, was granted authorization to engage in the manufacture and sale of optical goods and photographic supplies in Ohio. It operated stores in several cities of the state. Contending that the corporation was illegally engaged in the practice of optometry, the state on the relation of the attorney general instituted in the Supreme Court of Ohio an action in quo warranto against it.

Prior to April 1935 the corporation employed licensed optometrists to act as managers of its optical business and in connection therewith to practice optometry. For all of such services, whether as managers or as optometrists, they received a salary and commission paid by the corporation. Subsequent to the date named, the arrangement was changed by a written contract providing that, in consideration of the optometrist referring to the corporation patients desiring glasses on prescription and of the corporation referring to the optometrist all of its patrons desiring an examination of the eyes, the corporation leased to the optometrist certain office space in its place of business and permitted the optometrist to use certain equipment owned by the corporation for the examination of eyes. For examining eyes the optometrist agreed not to charge in excess of \$1, no part of which was to go to the corporation. The optometrist further promised to sell to the corporation, after the termination of the contract, all of his prescription files for \$1. Practically all patients who went to the optometrist were customers of the corporation and were attracted, to some extent, by advertisements inserted by the corporation in the daily newspapers. While customers might take the prescriptions given by the optometrist to any optician, spectacles were customarily obtained from the corporation, which sent the prescriptions to its home office at Pittsburgh, where the lenses were ground and mounted in frames.

A corporation, said the Supreme Court, may not directly or indirectly engage in the practice of optometry in Ohio. An incorporated optical company may lease an office or equipment to an optometrist and even carry his advertisements with its own. But while the optometrist is practicing his profession in such office and with such equipment, the corporation may not employ him in its optical business. If this course were permitted, the optometrist could bargain for and obtain such a high salary from his employer that he could afford to serve customers free of charge or for a nominal fee. In this way the amount of salary he could demand would be greatly augmented by attracting customers to the optical business through inexpensive optometric services. The optometrist would become a mere adjunct of the optical business, and the corporation in effect would be practicing optometry. The practice of the optometrist must be wholly separate from and independent of

the business of the optical company. Where the optometrist leases quarters or equipment, or both, from the optical company, the latter may receive prescriptions for eyeglasses from such optometrist the same as from any other. The optical company, however, may not lawfully exercise any control over the optometrist nor may it fill prescriptions issued by an optometrist legitimately employed by it. It may not advertise in such a way as to lead the public to believe that it does the work of the optometrist or do anything through an employee that amounts to the practice of optometry, even though such employee is an optometrist. The corporation may not enter into a contract with the optometrist by which the optometric work of the latter is regulated or controlled, in the prices to be charged, the customers to be served, or the manner of doing the work. Neither may the corporation retain nor acquire control over or ownership of or interest in any records, copies of prescriptions, or prescriptions of the optometrist.

A judgment was therefore entered against the corporation, ousting it from engaging directly or indirectly in the practice of optometry in Ohio.—*State ex rel, Bricker, Atty. Gen., v. Buhl Optical Co. (Ohio)*, 2 N. E. (2d) 601.

## Society Proceedings

### COMING MEETINGS

- Alabama, Medical Association of the State of, Birmingham, April 20-22. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.
- American Association for the Study of Neoplastic Diseases, Philadelphia, April 9-10. Dr. E. R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Anatomists, Toronto, Ont., March 25-27. Dr. George W. Corner, 260 Crittenden Blvd., Rochester, N. Y., Secretary.
- American Association of Pathologists and Bacteriologists, Chicago, March 25-26. Dr. Howard T. Kaisner, 2085 Adelbert Road, Cleveland, Secretary.
- American Association on Mental Deficiency, Atlantic City, N. J., May 5-8. Dr. E. Arthur Whitney, Elwyn, Pa., Secretary.
- American College of Physicians, St. Louis, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia, Executive Secretary.
- American Pediatric Society, University, Va., April 29-May 1. Dr. Hush McCulloch, 325 North Euclid Ave., St. Louis, Secretary.
- American Physiological Society, Memphis, Tenn., April 21-24. Dr. A. C. Ivy, 303 East Chicago Ave., Chicago, Secretary.
- American Society for Clinical Investigation, Atlantic City, N. J., May 3. Dr. J. M. Hayman Jr., 2065 Adelbert Road, Cleveland, Secretary.
- American Society for Experimental Pathology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- American Society for Pharmacology and Experimental Therapeutics, Memphis, Tenn., April 21-24. Dr. E. M. K. Geiling, 947 East 58th St., Chicago, Secretary.
- American Society of Biological Chemistry, Memphis, Tenn., April 21-24. Dr. H. A. Mattill, Chemistry Building, State University of Iowa, Iowa City, Secretary.
- Arizona State Medical Association, Yuma, April 1-3. Dr. D. F. Harbridge, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 12-14. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.
- Association of American Physicians, Atlantic City, N. J., May 4-5. Dr. Hugh J. Morgan, Vanderbilt University Hospital, Nashville, Tenn., Secretary.
- California Medical Association, Del Monte, May 2-5. Dr. F. C. Warnshuis, 450 Sutter St., San Francisco, Secretary.
- District of Columbia, Medical Society of the, Washington, May 5-6. Dr. C. B. Conklin, 1718 M St. N.W., Washington, Secretary.
- Federation of American Societies for Experimental Biology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- Florida Medical Association, St. Petersburg, April 5-7. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Hawaii Territorial Medical Association, Hilo, April 30-May 2. Dr. Douglas B. Bell, Queen's Hospital, Honolulu, Secretary.
- Kansas Medical Society, Topeka, May 3-6. Mr. Clarence G. Munns, Stormont Bldg., Topeka, Executive Secretary.
- Louisiana State Medical Society, Monroe, April 26-28. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, April 27-29. Dr. Walter Dent Wise, 1211 Cathedral St., Baltimore, Secretary.
- Minnesota State Medical Association, St. Paul, May 3-5. Dr. E. A. Meyerding, 11 West Summit Ave., St. Paul, Secretary.
- New Jersey, Medical Society of, Atlantic City, April 27-29. Dr. J. B. Morrison, 66 Milford Ave., Newark, Secretary.
- North Carolina, Medical Society of the State of, Winston-Salem, May 3-5. Dr. L. B. McBrayer, Southern Pines, Secretary.
- Ohio State Medical Association, Dayton, April 28-29. Mr. C. S. Nelson, 79 East State St., Columbus, Executive Secretary.
- South Carolina Medical Association, Columbia, April 13-15. Dr. E. A. Hines, Seneca, Secretary.
- Tennessee State Medical Association, Knoxville, April 13-15. Dr. H. H. Shoulders, 706 Church St., Nashville, Secretary.
- Western Branch of American Public Health Association, Phoenix, Ariz., April 13-15. Dr. William P. Shepard, 600 Stockton St., San Francisco, Secretary.

ciated pigmentation resulting from a clumping of pigment cells (chromatophores) or from melanoblasts produced by stimulation of cells as the result of the local irritation.

While there will probably be some decrease in the pigmentation over a period of time, the possibility of residual pigmentation of a permanent character is not unlikely. Success in removal of this pigment will depend a great deal on the depth of the pigment cells in the skin. The use of the cautery, carbon dioxide snow or other superficial destructive measures may be necessary to secure complete eradication of the pigment after sufficient time has elapsed to allow for spontaneous involution.

#### EFFECTS OF ARSPHENAMINE IN CANCER

*To the Editor:*—Does the administration of arspenamine to a patient suffering from cancer of the gastro-intestinal tract, but not having syphilis, have a deleterious effect? That is, does it stimulate the growth and hasten the patient's death? I shall appreciate your giving me references on this subject. It seems that the literature is not very specific. Please omit name.

M.D., Ohio

*ANSWER:*—There seems to be no authentic evidence indicating that the administration of arspenamine to a patient suffering from gastro-intestinal cancer stimulates the growth or hastens death.

#### OPACITY OF CORNEA IN DOGS

*To the Editor:*—Recently there appeared in *Queries and Minor Notes* an inquiry by M.D., Pennsylvania, relative to opacity of the cornea in dogs. Unfortunately, no statement was made as to the age and breed of the animal and whether or not the animal was or had been suffering from any constitutional ailment. No mention was made of the presence or absence of vascularization and the extent, depth or form of the opacity. Primarily opacities of the cornea usually appear as leukoma in dogs. In most cases they apparently are noninflammatory and appear to arise spontaneously and are not related to trauma. They frequently disappear with treatment and will later recur. Vitamin A deficiency is not an etiologic factor in these cases. In a few cases the opacity results from an interstitial keratitis. Leukoma frequently accompanies an attack of distemper and it is comparatively resistant to treatment. However, inflammatory changes are absent in these cases, in contradistinction to ulcerative keratitis, which also occurs frequently in this disease.

It appears that breeds such as the Boston terrier, with protuberant eyes, are more commonly affected.

In spite of the fact that treatment has not been very successful, application of the following agents may greatly help to cause resolution of the opacity: massage with 5 per cent yellow mercuric oxide ointment three times a day; instillations of ethylmorphine hydrochloride or intramuscular injections of from 5 to 10 cc. daily of sterile milk and potassium iodide in 2 grain (0.13 Gm.) doses three times a day. While there is nothing new about this treatment, the results obtained amply justifies its usage. However, it is necessary to apply this treatment for weeks and months, as some of these cases take a long time to clear up.

The diet should consist of plenty of raw or cooked meat, milk, cereals and very little vegetables.

FRANK BLOOM, D.V.M., Flushing, L. I., N. Y.

#### BENZENE POISONING

*To the Editor:*—A case of benzene poisoning referred to in *Queries and Minor Notes* on page 2073 of the Dec. 19, 1936, issue of *THE JOURNAL* prompts me to communicate to you an observation made recently in a case of severe chronic benzene poisoning.

The patient, a worker engaged on the benzene plant of a gas works, showed symptoms like those of scurvy (hemorrhagic purpura, leukopenia, dental hemorrhagia, relative lymphocytosis). I therefore proceeded to the determination of his vitamin C deficiency with the help of the "saturation test," outlined by Harris and Ray (*Lancet* 1:71 [Jan. 12] 1935). Cevitamic acid was administered in daily doses of from 200 to 400 mg. intravenously and orally. To my amazement, 11.5 Gm. of cevitic acid (of which 6.3 Gm. was given intravenously) was necessary before saturation was attained, recognizable by excretion of the excess of cevitic acid in the urine. This quantity is equivalent to the maximum amounts of cevitic acid necessary, according to the literature, for covering vitamin C deficiency in cases of severe scurvy. After saturation was reached, the objective and subjective state of the patient had been greatly improved, but he still needed rather high amounts of cevitic acid to cover his daily requirements (after three weeks of normal diet 0.9 Gm. of cevitic acid was again necessary to "saturate" him). The relationship between benzene poisoning and vitamin C deficiency is being discussed in a paper which I have submitted to the *Zeitschrift für Vitaminforschung*. My experience has just been corroborated in the paper of Cathala, Bolgert and Grenet: *Scorbut chez un sujet soumis à une intoxication benzolique professionnelle* (*Bull. et mém. Soc. méd. d. hôp. de Paris* 52: 1648 [Dec 21] 1936), describing a similar case which was successfully treated with vitamin C in the form of high doses of lemon juice. According to guinea-pig tests carried out together with Dr. V. Demole of Basle, chronic benzene poisoning inhibits the normal storing of cevitic acid in the adrenals and liver and increases the demand for vitamin C. In cases of benzene poisoning it seems therefore worth while to keep in mind the possibility of vitamin C deficiency and eventually remedy it.

A. MEYER, M.D., Basle, Switzerland.

## Council on Medical Education and Hospitals

### BUSINESS MEETING HELD BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS IN CHICAGO FEB. 14, 1937

1. The meeting was called to order at 10:30 a. m. Those present included Drs. Ray Lyman Wilbur (chairman), Charles E. Humiston, Frederic A. Washburn, John H. Musser, Fred Moore, Reginald Fitz, Fred W. Rankin, William D. Cutter (secretary), Herman G. Weiskotten, Carl M. Peterson, Oswald N. Andersen and Mr. Homer F. Sanger. Also present were Dr. Charles Gordon Heyd, President, and Dr. Olin West, Secretary of the American Medical Association.

2. It was resolved that the minutes of the business meeting of Oct. 11, 1936, be approved.

3. Concerning schools that do not offer a complete medical course, the following statement was prepared and approved:

#### SCHOOLS OF THE MEDICAL SCIENCES

Following the recent survey of the medical schools it was decided that, effective July 1, 1939, the Council will publish a list of schools which teach acceptably gross and microscopic anatomy, biochemistry, physiology, pharmacology, bacteriology and pathology, even though they do not offer a full course leading to a medical degree.

The acceptance of courses involving the use of clinical material shall be left to the discretion of the faculties which admit to advanced standing students transferring from approved schools of the medical sciences.

Surveys of the clinical courses and facilities will be made by the Council and reported to the individual medical schools upon request.

4. It was resolved that the American Board of Obstetrics and Gynecology be approved.

5. It was resolved that the American Board of Internal Medicine be approved.

6. It was voted to approve the lists of schools for clinical laboratory technicians recommended by the staff.

7. It was voted to approve the lists of hospitals and other institutions recommended by the staff.

8. It was resolved that the Council on Medical Education and Hospitals express to Dr. Herman G. Weiskotten of Syracuse and Rev. Alphonse M. Schwitalla, S.J., of St. Louis its profound appreciation of their invaluable service in connection with the appraisal of medical schools and the preparation of pattern maps, and the secretary was instructed to convey to these gentlemen an official acknowledgment of its indebtedness to them for so important a contribution to the success of the survey.

WILLIAM D. CUTTER, M.D., Secretary.

#### ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in *THE JOURNAL*, Oct. 24, 1936:

#### Hospitals Approved for Intern Training

U. S. Naval Hospital, Mare Island, Calif.  
U. S. Naval Hospital, San Diego, Calif.  
Franklin Hospital, San Francisco.  
U. S. Naval Hospital, Washington, D. C.  
Broadlawn Polk County Public Hospital, Des Moines, Iowa.  
Providence Hospital, Kansas City, Kan.  
U. S. Naval Hospital, Chelsea, Mass.  
Leila Y. Post Montgomery Hospital, Battle Creek, Mich.  
St. Louis County Hospital, Clayton, Mo.  
Evangelical Covenant Hospital, Omaha.  
U. S. Naval Hospital, Brooklyn.  
Braddock General Hospital, Braddock, Pa.  
Nesbitt Memorial Hospital, Kingston, Pa.  
U. S. Naval Hospital, Philadelphia.  
Valley Hospital, Sewickley, Pa.  
Norfolk Naval Hospital, Portsmouth, Va.

#### Hospitals Approved for Residencies in Specialties

Grace Hospital, New Haven, Conn. Medicine and surgery.  
Mount Sinai Hospital, Chicago. Pathology.  
Ball Memorial Hospital, Muncie, Ind. Pathology.

cystic mastitis. Added to these are various conditions of the breast, so that when the patient asks of the doctor: Do you think I should have my breast removed to avoid possible danger in the future? the doctor is forced to answer in the affirmative. A well planned amputation, carefully performed with a preliminary full thickness nipple graft, will allow removal of all lumps and the salvaging of sufficient skin and fat to form an acceptable, normal looking breast. If an acceptable, non-functional cosmetic breast can be offered to patients who are procrastinating against breast surgery through fear of deformity until too late, another helping hand will be contributed in the fight on cancer.

Correction of Some Problems in State Medicine. H. A. Walker, Miami Beach.—p. 330.

**Dermatitis Venenata.**—Kirby-Smith divides his discussion of dermatitis venenata into forms due to chemicals, cosmetics and plants. He has found that in Florida ivy poison is of minor consideration but that there are some sixty-odd shrubs, plants and flowers producing skin irritations. Any oily or greasy preparation should not be used on acute dermatitis of plant origin. If available, an air-cooled ultraviolet ray treatment (full erythema dose) will bring about a prompt evolution. Alcoholic preparations with salicylic acid or aluminum acetate are recommended or continued very hot or very cold wet dressings of some mild antiseptic or astringent character, boric acid solution, black wash or saturated solution of sodium thiosulfate. After the termination of the inflammation, some simple emollient should be used for comfort.

**Bone Chips in Treatment of Osteitis Fibrosa.**—Freund treated seven cases of localized osteitis fibrosa by packing the curetted cavity with chips of bone obtained from the affected limb or, when necessary, from both tibias. The use of bone chips was found to be superior to simple scraping and the use of caustic substances. The cavity can be filled much more

easily with chips than with solid cortical bone grafts, and it seems also that the power of osteogenesis is greater with the use of chips. Giant-cell tumors are not so susceptible to this form of treatment, especially if they are in the more advanced stage and if too great a defect results after the curettage of the tumor tissue. Nevertheless, the author obtained a very good result in one case in which the entire lateral condyle was involved. Care should be taken to fill the defect with the chips as completely as possible. In too advanced cases or in recurrent cases of giant-cell tumor, resection with heavy, bridging, tibial grafts is preferable to the less radical procedures, such as curettage and the use of bone chips, and to the more radical ones, such as amputation and exarticulation.

**Method of Treating Fracture of Clavicle.**—For the last ten years, Hawley has used the following method for fractures of the clavicle: The patient, either standing or sitting on a stool, is requested to hold his head erect and to square his shoulders like a West Point cadet. The end of a strip of adhesive plaster is fastened to the skin in front of the head of the humerus. The opposite arm in abduction is pulled into hyperextension and used as a lever, while the adhesive plaster under strong tension is anchored to the opposite wall of the chest. This acts to pull the shoulder girdle back and to hold it securely. Several strips of plaster are applied in like manner, a double thickness of plaster being used for added strength. Then a cap of adhesive plaster is applied over the shoulder to anchor the anterior ends of the first plaster and to protect the site of fracture. For the first week the arm is carried in a sling, following which the patient is allowed to take the arm out of the sling for meals. The sling is discarded when healing is under way and confidence returns. The plaster is reapplied every week for three or four weeks, the same tension being used to hold the reduction.

**Bilateral Symmetry of Skin Temperature.**—As a part of a biologic analysis of adaptive functions in schizophrenia, Freeman and his colleagues studied the differences in skin temperature between the right and left sides in nine symmetrically located areas on the body surface of twenty normal and twenty schizophrenic individuals. Seven readings were made on each point at intervals of thirty minutes with the environmental temperature held at 75.2 F. and the relative humidity at 20 per cent. 1. In both normal and psychotic individuals the trunk on the left and the extremities on the right have the higher skin temperatures. 2. Individuals differ significantly from one another relative to the magnitude of the differences between the temperatures of symmetrically located areas. In this respect patients with schizophrenia differ from one another

## Book Notices

**Research in Dementia Praecox (Past Attainments, Present Trends and Future Possibilities).** By Nolan D. C. Lewis, M.D., Professor of Neurology, Columbia University. Cloth. Price, \$1.50. Pp. 320. New York: National Committee for Mental Hygiene, 1936.

The author spent a year in the service of the thirty-third degree Masons, investigating investigators of dementia praecox for the purpose of adequately distributing a large sum of money set aside by the Masonic order for research in dementia praecox. The fact that the majority of the sum available was allocated to the members of the advisory committee for the continuation of orthodox psychiatry, already languishing under their direction for some decades, might have been compensated for by this survey of existing research ventures in this country. The first chapter indicates the polarities of organic and psychologic points of view and pleads indirectly for a more unified concept of the problem. Then follow utterly useless correlations of the published works from many countries, classified into respective fields of science and variations of approach. There are then five chapters concerned respectively with clinical features, etiology, alterations in structure and structure function (whatever that means), differential diagnosis and therapy. A chapter of conclusions follows. Each chapter is followed by a lengthy bibliography, divided according to year of publication, obviously derived from the index without reading or digestion, as these titles show little correlation with the subject matter of the chapters. As one peruses the material in each chapter one is struck by the numerous quotations from authorities in the mental sciences expressed as ex cathedra pronouncements. However, there is little actual detail concerning what the book purports to present; namely, what American scientists are doing in the field of dementia praecox. In fact, one begins to wonder whether the author actually entered the laboratories of the scientists he visited or limited his investigations to conversations around the luncheon table. The sparsity of these details is not made up for by the inclusion of several of the author's own case abstracts. Certainly the nonclinical investigator could not understand what dementia praecox is from this book. In his short concluding chapter the author outlines what he considers is a plan of procedure in psychiatric research which is as vague as any plan not based on actual working knowledge of the needs of fundamental workers in the field. It indicates, for example, the need of money, the need for propaganda, and the need for scientists well controlled by committees of authorities acting as coordinators. There are no constructive ideas embodied in his plan. Lewis has had a splendid opportunity for learning what is going on in American psychiatry and plucking from the laboratories concerned with the technics of the basic sciences that which can be utilized or modified for the solution of the human plague dementia praecox. His book as a representation of his year's activity indicates the failure of his work and bodes ill for the future "circuit riders of psychiatry."

**Endocrinology in Modern Practice.** By William Wolf, M.D., M.S., Ph.D. Cloth. Price, \$10. Pp. 1,018, with 252 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

The current years have seen a crowded market for volumes devoted to endocrinology, the result, no doubt, of the tremendous stimulation of research that has occurred in this field. In his preface the author indicates the trepidation with which he undertook the production of this work and his desire to develop a volume primarily for the general practitioner. This volume includes special chapters devoted to each of the glands and then sections concerning various types of disorders recognized as glandular. Supplementing these special considerations is the second portion of the book, which is concerned with the various systems of the body and special medical groups so far as they are concerned with glandular disturbances. The final two divisions are devoted to endocrine diagnosis and endocrine preparations. The volume is illustrated with a considerable number of pictures derived from many different sources. Its organization follows the standard classification developed in Osler's textbook, and each of the chapters is supplemented by a tabular concentration or outline of what has gone before. In a field in which there is vast overenthusiasm and much

diffuse knowledge, the author provides an excellent summary. Obviously, most of the doubt in this field is concerned with the application of the knowledge to therapy. Here again the author has exercised admirable restraint in his recommendations. Another unusual feature of the book is the chapter on symptom diagnosis, which is an index by symptoms to each of the special considerations to be found in the volume. The book should be useful to all interested in the field, not so much for its primary contribution as for its value as an outline of our current knowledge.

**The Nutritive Value of Fruits, Vegetables and Nuts.** By R. A. McCance, E. M. Widdowson and L. R. B. Shackleton. Medical Research Council, Special Report Series, No. 213. Paper. Price, 2s. Pp. 107, with 26 illustrations. London: His Majesty's Stationery Office, 1936.

This is the third in a series of reports on the chemical composition of foods commonly eaten in Great Britain. Many of the methods used in the study of the carbohydrate content of foods (No. 135 in this series) and the chemistry of flesh foods and their losses in cooking (No. 187) were applicable to this study, but methods for the determination of carbohydrates, copper, total and phytin phosphorus, iron and potassium are briefly described and likewise certain modifications in the procedures for determining chlorine and sodium. Analyses are reported on forty-eight samples of fruit and on eighty-two of vegetables, with regard to total available carbohydrate, protein, fat, sodium, potassium, calcium, magnesium, iron, copper, phosphorus and chlorine. Nine varieties of nuts have been similarly analyzed, with the addition of figures for sucrose and starch separately and for "available" nonphytin phosphorus, on the assumption from previous work (McCance, R. A., and Widdowson, Elsie May: *Biochem. J.* 29:2694 [Dec.] 1935) that phytin phosphorus is not readily available in human nutrition and should be deducted from the total phosphorus.

To offset the disadvantages of analysis of a single sample of a given food, the sample was in each case an aliquot of several samples of the same food grown under different conditions but in the same season. These analyses make valuable additions to our data on a large number of foods. The available carbohydrate includes reducing sugars, sucrose and starch. Starch, protein and fat were determined on the alcohol-insoluble residue, and their sum, deducted from the total alcohol insoluble residue, is called "roughage." Thus the error in the method of the Official Agricultural Chemists of the United States inherent in calculating total carbohydrates "by difference" and determining crude fiber directly is in the case of fruits and vegetables largely transferred to the so-called roughage. In spite of these differences in procedure in the two countries the data for many of the foods compare as closely as could be expected with those of Atwater and Bryant (Bull. 28, U. S. Dept. of Agriculture) or later compilations of Chatfield and Adams (Circular 146, U. S. Dept. of Agriculture, 1931) for fresh vegetables and Chatfield and McLaughlin (Circular 50, U. S. Dept. of Agriculture, 1928) for fresh fruits. The error introduced by using the figure for carbohydrates "by difference" is usually well within the range of values for maximum and minimum on the same food. Thus twenty-nine samples of apples reported by Atwater and Bryant ranged from 8.8 to 21.3 per cent total carbohydrates by difference, averaging 14.2 per cent, with 1.0 per cent fiber, making available carbohydrate 13.2 per cent, while two types of English apples averaged from 9.6 to 12.2 per cent of available carbohydrate with 2.4 and 1.7 per cent of fiber respectively. These differences are so much less than the natural range of samples of the same food that, while it is certainly desirable to have such careful determinations of available carbohydrate, the results of calculation by either method are probably satisfactory for all purposes for which they can be applied. It seems difficult for many workers to realize the enormous variation in vegetable products. When precision is necessary, determinations must be made on every sample used.

In the case of nuts, there is a considerable portion of the total carbohydrate not present as starch or sugar but existing in the form of hemicelluloses, such as pentosans and galactans and cellulose. Morgan, Strauch and Blume (*J. Biol. Chem.* 85:885 [Jan.] 1930) found only 48 per cent of almond carbohydrate available and Neale (*J. Am. Dietet. A.* 2:73 1926), investigating peanut meal, found that only about 30 per cent of the carbohydrate estimated by difference was available, or 47 per

197-1950

into the gland. Small amounts of solution are deposited at three or four points, radially or fanwise. After two or three treatments to the body of the gland, the upper and lower portions of the gland are treated in an attempt to produce fibrosis in the region of the blood supply to the gland. Each time the point of the needle is changed, retraction on the plunger of the syringe is made in order to determine whether or not the point is in a blood vessel. Owing to the variability in the size and lobular thickness of the thyroid, extreme care must be used in making deep injections to prevent the formation of fibrosis on the posterior surface of the thyroid, which might involve the parathyroids and cause serious or troublesome complications. The author reports five typical cases from his series, and states that the solutions used will be reported in a subsequent article.

**Sympathectomy in Treatment of Vascular Disease.**—Smithwick discusses the results of sympathectomy in Raynaud's disease, thrombo-angiitis obliterans, angina pectoris and essential hypertension. The clinical results of sympathectomy vary a great deal, depending on which portion of the pathway is divided, and are far better if the preganglionic portion is interrupted. When a blood vessel is totally disconnected from the central nervous system, residual vascular spasm will appear after a short period (weeks) in response to cold, pain and emotion. The amount of residual spasm is more than twice as great when sympathectomy is accomplished by postganglionic section rather than by preganglionic section. Residual vascular spasm can be largely eliminated by denervation of the adrenals in animals and, presumably, also in man. The best and most lasting results of sympathectomy for vascular disease will be obtained by preganglionic section, with denervation of the adrenals if necessary. The operative results in Raynaud's disease are most striking early in the disease; that is, before marked local changes have taken place. The best results are obtained in the early and moderately advanced cases, the hands being constantly warm, dry and pink. Even in the advanced group the abolition of color change and the dryness produced make the result worth while, even though there may be only a slight elevation of surface temperature. In contrast to Raynaud's disease, thrombo-angiitis obliterans is primarily an obliterative vascular disease. In the early stages perhaps one case in ten will show a striking rise in surface temperature of the tips of the digits (from 10 to 20 degrees F.), when the sympathetic nerve supply is interrupted by peripheral nerve block, by paravertebral lumbar sympathetic block or by spinal anesthesia. Under such circumstances, lumbar sympathectomy is indicated and has been well worth while. It is rarely necessary to perform a dorsal sympathectomy in this disease. Peripheral nerve block, induced by crushing or by alcohol injection, which not only produces temporary anesthesia but also temporarily sympathectomizes the anesthetic area, has a wider field of application in the treatment of this disease. It should frequently be followed by lumbar sympathectomy after

the nerves regenerate. In the treatment of angina pectoris, as there are no white rami above the first thoracic ganglion, any pain pathways descending the cervical sympathetic trunk, as well as those carried by the direct thoracic cardiac nerves, can be interrupted in the upper dorsal levels, while cervical sympathectomy will fail to interrupt the painful impulses carried by the direct thoracic cardiac nerves. Complete sensory denervation of the heart can therefore be accomplished by excision of the upper four to six thoracic ganglions or by sectioning the rami between these ganglions and the corresponding intercostal nerves. Most patients with angina pectoris are not good subjects for an operation of this magnitude, and experience has shown that paravertebral alcohol injection is equally satisfactory and carries a negligible risk and very little disability. This has become the treatment of choice. Splanchnic resection for essential hypertension offers a high degree of symptomatic relief to patients suffering from this disease. When performed early in the disease, a high percentage of cases will obtain a material lowering of blood pressure level. Further observation is necessary to decide whether this will result in arrest or cure of the disease in the early stages and whether, even in the absence of blood pressure change, the course of the disease in its later stages is materially altered.

**Dermatomyositis.**—Against the possibility that a filtrable virus is the cause of the disease there is some determining evidence in one of Turner's patients in whom the disease recurred after complete remission for several years. Most virus infections after recovery confer a permanent immunity. The history of sensitivity to sunlight in two of the patients hinted at the possibility of a disturbance in porphyrin metabolism. The specimens of urine were always yellow, both before and after exposure to the sun, and no abnormality in porphyrin content could be detected spectroscopically. The skin lesions were unlike those of pellagra and there was no evidence of a dietary deficiency. The parenteral administration of crystalline preparations of vitamins B and C in moderately large dosage had no effect. Attention is called to the suggestion of Köster that perhaps the vascular system is the seat of the primary disturbance. In case 2 the albumin content of the subcutaneous edema fluid was almost precisely that of the blood serum. Since biopsy of muscle failed to demonstrate inflammatory or degenerative changes, it may be argued that the high edema fluid protein signified an abnormal vascular permeability independent of inflammation. However, it cannot be denied that inflammatory and degenerative changes do occur in many cases, and these factors no doubt then play an important part in the edema that is so characteristic of the disease.

This interesting analysis of the medicine of ancient Greece is, of course, based on such evidence as is available in the writings of Hippocrates and Galen and others of the period, and on such works as those of Neuburger and Garrison on the history of medicine. The biographic sketch of Galen is of exceeding interest. The author has been especially attracted to the philosophy underlying the medical practices of the ancients. The book contains numerous well chosen quotations from earlier writings and a few interesting illustrations.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Medical Practice Acts: Administration of Anesthetics by Nurses.**—Two practicing physicians, on behalf of themselves and all other physicians, filed a petition for an injunction to restrain the defendant nurse, employed by the defendant hospital, from administering general anesthetics in connection with operations. Such practice, it was contended, constituted a violation of the medical practice act of California. The trial court gave judgment for the defendants, and the plaintiffs appealed to the Supreme Court of California.

The findings, said the Supreme Court, show conclusively that everything that was done by the nurse in the present case, and by nurses generally, with respect to the administration of anesthetics, was and is done under the immediate direction and supervision of the operating surgeon and his assistants. Such method, said the court, seems to be the uniform practice in operating rooms. The court continued:

There was much testimony as to the recognized practice of permitting nurses to administer anesthetics and hypodermics. One of the plaintiffs' witnesses testified to what seems to be the established and uniformly accepted practice and procedure followed by surgeons and nurses, and that is that it is not diagnosing nor prescribing by the nurses within the meaning of the Medical Practice Act. We are led further to accept this practice and procedure as established when we consider the evidence of the many surgeons who supported the contention of the defendant nurse, and whose qualifications to testify concerning the practice of medicine in this community and elsewhere were established beyond dispute. That such practice is in accord with the generally accepted rule is borne out by the decided cases.

Furthermore, said the court, aside from the proposition that nurses in the surgery during the preparation for and progress of an operation are not diagnosing or prescribing within the meaning of the medical practice act, it is the legally established rule that they are carrying out the orders of the physicians to whose authority they are subject. The surgeon has the power, and therefore the duty, to direct a nurse in her actions during the operation.

The judgment of the trial court for the defendants was therefore affirmed.—*Chalmers-Francis et al. v. Nelson et al.* (Calif.), 57 P. (2d) 1312.

**Evidence: Credibility of Professional Expert Witness.**—The plaintiffs, husband and wife, instituted suit against the defendant for damages, alleging that the defendant's agent, July 17, 1932, negligently caused a screen door to strike the wife violently on her abdomen and that this blow caused three miscarriages, one on Sept. 11, 1932, the second on Feb. 19, 1933, and a third on June 30, 1935. The trial court gave judgment for the plaintiffs, and the defendant appealed to the Supreme Court of Pennsylvania.

The wife's physician, testifying as her witness, stated that no one can tell with any degree of certainty what causes successive abortions such as the wife suffered. He was unable to specify the cause in this case. Another physician, who attended the wife at the hospital following her last abortion and who operated on her, was not called as a witness by the plaintiffs but was placed on the stand under subpoena by the defendant.

He stated that the wife's condition when he attended her was not caused by the injury three years previous thereto, and that in his opinion the abortion was brought on by an attack of "la grippe." In order to supply the deficiency in their proof as to the cause of the abortions, the plaintiffs called a "professional expert witness, who had been testifying in the courts of Allegheny county as an expert for thirty years." This witness had not attended the wife at any of the miscarriages and had not seen the hospital records. He testified, however, that in his opinion the successive abortions were due to the striking of the wife by the screen door. Concerning this witness, the Supreme Court of Pennsylvania quoted as follows from *Murphy v. Pennsylvania R. R. Co.*, 292 Pa. 213, 140 A. 867:

The professional expert, whose testimony we relate above, frequently appeared in court as a witness in personal injury cases, and the inference from his evidence is that he made the giving of testimony in such actions a business. One of the evils in the trial of personal injury cases is padding the claim with evidence of the professional medical expert. When considering a motion for a new trial, based on an excessive verdict, ordinarily but little weight should be given to such testimony.

After examining the evidence in the case, the Supreme Court was convinced that the verdict was excessive and that a new trial should have been granted, not alone because of the excessiveness of the verdict but because of the unsatisfying state of the evidence.—*Nickolls v. Personal Finance Co. (Pa.)*, 185 A. 286.

**Malpractice: Alleged Negligent Care After Childbirth.**—The defendant, an obstetrician, attended the patient during childbirth, Aug. 4, 1931. At the time of the delivery, the defendant made an incision in the plaintiff's perineum to prevent its rupture and sutured the incision after the delivery. The plaintiff claimed that shortly after she left the hospital she noticed a discharge of pus from the "sutured holes" and felt pain and that despite numerous telephone calls to the defendant he neglected to attend her until September 15, when, according to her contention, he told her that she was all right. Subsequently she went to another physician, who discovered a sinus in her perineum which developed into a fistula. Two operations were necessary before the plaintiff obtained relief. Suit was instituted against the defendant and a verdict for the plaintiff was set aside by the trial court. The plaintiff appealed to the Supreme Court of Errors, which upheld the action of the trial court. *Green v. Stone* (Conn.), 176 A. 123; abstr. THE JOURNAL, Oct. 12, 1935, page 1217. A second trial ensued, resulting in judgment for the defendant, and the plaintiff again appealed to the Supreme Court of Errors of Connecticut.

The defendant contended that the plaintiff made no complaint to him after leaving the hospital. He examined her, he claimed, on September 14 and found a "dimple" at the bottom of the incision in the perineum and on October 9 he discovered and treated a superficial sinus in the perineum. If there was a sinus present before October 9, the defendant contended, his failure earlier to discover and treat it was not the cause of the pain, suffering and expense resulting from the two operations.

The basis of the claim in this suit, said the court, was that due care on the part of the defendant required that he immediately investigate the complaints which the plaintiff claimed to have made to him shortly after her return from the hospital, and that if he had done so he would have discovered the small superficial sinus, which could then have been cured if treated promptly. There was no other allegation of negligent conduct on the part of the defendant. Whether the plaintiff made any such complaints was a sharply contested issue and the trial court did not err in charging the jury that if they believed that no such complaints were made, then their verdict should be for the defendant. An expert witness for the plaintiff testified at the first trial that no one could tell whether the recognized treatment of a sinus, if early applied, could have cleared up the plaintiff's condition. On the second trial, this witness changed his opinion and testified that the sinus could probably have been cured if treated promptly. The trial court in the second trial commented pointedly on this change of opinion. The plaintiff contended that these comments conveyed to the jury a lack of confidence on the part of the court in the testimony of this witness, and that this was unjustified and highly prejudicial to the plaintiff. That the witness

to chronic catarrhal deafness, and, at the same time, to include the origin and distribution of the eighth nerve and its communications in the temporal bone for possible neural stimulation. How roentgen therapy brings about improvement in cases of chronic catarrhal deafness may always remain in the realm of controversy.

**Bilateral Spontaneous Pneumothorax in Apparently Healthy Individuals.**—Hasney and Baum describe a case of idiopathic spontaneous bilateral pneumothorax in an otherwise healthy young person and review the recent literature on the subject. In commenting on the case they are inclined to accept Rossel's theory of "same effect, same cause." There was not the slightest evidence of active pulmonary tuberculosis. The parahilar annular shadows seen on the roentgenogram taken after bilateral reexpansion are, in their opinion, due to bullae described by Schmincke. The bilateral spontaneous pneumothorax was of the alternating type. The first rupture occurred on the right side and the second on the left before the right lung had had the opportunity to reexpand completely. During the third attack the left side collapsed, but an adhesion between the two left pleural layers, which must have formed after the reexpansion following the second attack, prevented complete compression of the left lung. The pneumothorax on the right following the third attack must have been so small and the opening of the superficial bulla so minute that the patient did not notice any discomfort. It was detected only by accident during the last roentgen check-up. As to the treatment of their patient, the authors admit that bed rest and strapping of the chest alone do not guarantee against a further accidental collapse. It is safer to continue the pneumothorax, first on the right, artificially for a while until the x-ray observations show a thickened visceral pleura which, after reexpansion, will remain adherent to the parietal layer. The irritation by artificially insufflated air alone is sufficient, in their opinion, and they would surely apply artificial pneumothorax on the left also if another accident should happen. They do not recommend the use of irritating substances other than filtered air intrapleurally. The ideal procedure in pneumothorax is to keep the pleural sac dry.

**Arterectomy.**—Leriche and his associates selected sixty consecutive cases, in which seventy-eight arterectomies were performed. The patients were seen one year, the majority more than three years and a few up to ten years after operation. There were no fatalities or serious complications in this series.

In the arteriosclerotic type of arterial occlusion, 54.5 per cent of the patients were definitely relieved of symptoms for a period of years. The thrombo-angiitis group, in about the same number of operations, produced satisfactory results in only 35 per cent. Patients representing five operations failed to return for follow-up examination. Two failures occurred in supposed syphilitic occlusions and three embolic failures occurred in unfavorable cases in which operation was delayed and gangrene had already set in. Ordinarily, if a case of embolism is seen early, arterectomy probably combined with ganglionectomy holds a definite hope for saving a limb, often when embolectomy has failed. The authors' best results in traumatic cases were those in which a fibrosed arterial cord could be resected, with subsequent relief of pain, cyanosis and edema. Since lumbar sympathectomy carries a mortality of 4 per cent or more, arterectomy, with its minimal surgical risk, should be the operation of choice in a majority of cases. Subsequent treatments with a passive vascular exercise unit or heat, massage and exercises may supplement arterectomy to give a greater percentage of fine results. Arterectomy is indicated in localized arterial occlusion of the extremities caused by senile arteriosclerosis, trauma, freezing, after surgical ligature and in favorable cases of embolus and thrombo-angiitis obliterans.

**Initiating Lesions of Renal Calculus.**—In offering a hypothesis for the origin of stone, Randall formulated two postulates and they have presented the basis for a series of research problems in an effort to prove or disprove their accuracy: first, that an initiating lesion had to exist; second, that any such lesion should be sought for on the renal papillae or close by. It has been a matter of constant observation on roentgen examination that most small calculi are found in the region of the renal papillae. Small renal calculi whose clinical existence has been of short duration (as judged by the patient's history), closely studied with a hand lens, have invariably presented on one side a uniform crystalline growth, while the opposite surface has shown a facet indicative of mural attachment. On examination of the kidneys from 104 necropsies, twelve presented evidence of an unusual picture and a new pathologic lesion. This lesion may be described as follows: On the papilla, generally on its lateral wall or near its tip, is seen an area, which for lack of a better term the author has called a "milk patch." It may be anywhere from the tiniest possible dot to an area measuring from 2 to 3 mm. in diameter, sharply outlined or delicately stellate in appearance and of uniform consistency, though some have shown centers which appear as though the material forming the "milk patch" had been deposited in circles. In all specimens of this character there is every evidence to suggest that the lesion is under the surface of the covering epithelial cells. Microscopic sections of the lesion have shown a deposit of calcium, entirely devoid of any inflammatory evidence, as being laid down in the wall of the renal papilla and in a position which is, in its earliest manifestation, entirely below the surface of the cells covering the papilla. The area involved appears to suffer a definite fibrosis, with changes in the blood supply, and the first deposit of calcium occurs in the cells lining the tubules, which, in turn, show different stages of aseptic necrosis. The next, or second, stage in the development of a stone is exemplified in a kidney removed from the body of a 46 year old man who died of left pyopneumothorax and cardiac failure. Each papilla in this kidney, with one normal papilla as an exception, showed the characteristic "milk patch" deposit; but on the surface of one such "milk patch" could be seen a tiny black dot. This dot is no larger than a grain of pepper or a cinder in an eye, but it stands out in clear distinction to the other papillary lesions of the first variety. Serial sections cut through this tiny speck show that the calcium deposited in this area has lost its covering epithelium and exists as a raw, exposed surface of calcium, at the periphery of which the epithelium dips down to an aseptic ulcer edge. The next, or third, stage in the development of a stone was found in a kidney from the body of a 56 year old woman who died of a malignant ovarian tumor and general carcinomatosis. This showed two papillae with the characteristic "milk patches" and a third papilla with a definite crystal deposit on a similar "milk patch," but in this case the crystal deposit measured approximately 2 mm. in diameter. It was densely adherent to the underlying tissue and, when sectioned, presented a characteristic papillary calcium plaque, and inti-

**The Electrocardiogram During Diabetic Coma.**—Certain observations suggested to Bellet and Dyer that rather marked and, on the whole, consistent alterations of the T waves and lengthening of the QT interval were present during certain stages of diabetic coma after the acidosis had been partially or completely controlled. This led to the observation of seventeen cases of diabetic coma and six cases of "precoma." Electrocardiographic changes were observed in every one of the cases studied by serial electrocardiograms during and on emergence from diabetic coma. The electrocardiographic changes of the coma cases were graded as severe in eight, moderate in six and slight in three; the electrocardiographic changes in the six precoma cases were similar, although less severe than were the changes of those patients who entered the hospital in coma. Only one showed severe electrocardiographic changes; four showed moderate and one slight changes. The chief alterations observed were lengthening of the QT interval, depression of the ST interval and inverted T waves. Alterations in the QRS complexes were infrequent. In all except three cases of the entire series of diabetic acidosis the electrocardiogram eventually returned to normal. The most abnormal electrocardiographic changes were observed not during coma but about twenty-four hours later when the patient was clinically improved and out of the acidotic state. Serial electrocardiographic studies may be an important method of gaging the severity of cardiac disturbance during and on emergence from diabetic coma.

#### Conservative Treatment of Trigeminal Neuralgia.

For the past ten years Ulanski has been using a certain form of electricity for the relief of pain in various nerve disorders. This form of electricity is a modification of the so-called rapid sinusoidal current. The rapid sinusoidal current is an alternating current, a voltage tracing of which would show as many positive and negative sines as there are cycles per second. Each positive phase is immediately succeeded by a negative phase of equal intensity; therefore the rapid sinusoidal current displays no polarity effects. This type of current possesses decided pain-relieving qualities. Favorable results obtained with it in sciatica and other forms of neuritis and neuralgia have suggested its application also for trigeminal neuralgia of both the major and minor forms. The author has treated cases in their incipience as well as those which have been previously treated by other methods. Of sixty-five cases treated there have been only nine failures. The period of relief varied from a few months to three or more years, with immediate response to repetition of treatment on the return of pain.

**Reconstruction of the Breast.**—Updegraff believes that surgery of the breast should always be undertaken for a very definite reason, either physical or mental, or the end results will not be acceptable to the patient. From the surgeon's standpoint there are three types of nonmalignant breast in considering reconstruction: 1. The moderately enlarged breast free from lumps that a simple mastopexy, without a lower keyhole incision in the skin flap or excision of the gland tissue, will rebuild. 2. The definitely enlarged breast needing a mastopexy, utilizing the keyhole incision and removing varying amounts of breast fat and tissue including an occasional lump. 3. The third type is the large nodular hypertrophic breast: for example, the painful lump in the breast occurring each period; also the polycystic fibromas and the breast of chronic

\*Periodic Somnolence and Morbid Hunger: New Syndrome. M. Levin.—p. 494.

**Periodic Somnolence and Morbid Hunger.**—Levin cites seven cases from the literature of what may be called "periodic somnolence-hunger," a syndrome characterized by attacks, usually lasting several days or weeks, in which the patient is excessively sleepy and hungry. Besides these cardinal symptoms, the attacks may be further marked by motor unrest and by irritability, difficulty in thinking, forgetfulness, incoherent speech and hallucinations. All these symptoms vanish in the intervals between attacks. The seven patients were all men, and in each the onset was in the second decade. In three the onset occurred soon after an acute illness (respectively, "grip," sore throat with fever and "influenza"). Fulton and others have shown that the frontal lobes contain centers which inhibit gastro-intestinal motility, their excision causing increased appetite, gastro-intestinal hypermotility and intussusception. These centers form part of the highest cerebral centers, more specifically, of the highest motor centers. The hypothesis is offered that "periodic somnolence-hunger" is due to excessive "inhibitability" or exhaustibility of the highest centers. The untimely and prolonged inhibition of these centers will explain the manifestations of the syndrome. Inhibition of the highest cerebral centers will explain the somnolence and the mental symptoms; inhibition of the centers described by Fulton, the hunger and the motor unrest. Excessive inhibitability of the highest centers is probably the result of some alteration of their component cells.

Carcinoma of the Breast. J. E. A. Lynham.—p. 60.

**Calcified Intracranial Tuberculomas.**—Martin states that calcified intracranial tuberculomas are usually discovered in patients who come under observation because of fits. They are not ordinarily associated with signs of intracranial pressure. The patients usually present evidence or history of tuberculosis elsewhere in the body. The age of the patients in the cases referred to ranged from 12 to 57 years. In the author's experience, calcified tuberculomas are usually situated in the cerebral hemispheres; they may, however, be situated under the tentorium. The majority of them lie near the surface of the brain. In a large proportion of cases, two or more such calcified lesions are present. They are very variable in size. By the time they are discovered by x-rays they are usually densely calcified. The shadows which they cast on the films are often very irregular, with a tendency to a lobulated appearance, and have a jagged or serrated outline. When calcification is not uniform throughout, it is most intense at the periphery or part of the periphery of a mass. For this reason the masses are sharply demarcated. These appearances correspond with the physical characters of extinct tuberculomas removed from the brain by

operation or at necropsy. The chief distinguishing features roentgenologically, from calcified tumors, are the sharp delimitation and very rough or jagged surfaces. The intensity of calcification may also serve as a guide in many cases.

Pentothal Sodium Anesthesia. O. J. Murphy.—p. 1308.

**Referred Pain Associated with Dysmenorrhea and Labor.**—Theobald states that stimulation of the autonomic nerve endings in the cervix by silver nitrate causes a referred pain appreciated in the area of the skin supplied by branches of the first lumbar nerve. This pain may be abolished by local anesthesia. Dysmenorrhea is largely, if not entirely, a referred pain appreciated in the area of skin supplied by branches of the first lumbar nerve, and the pain may be abolished by local anesthesia. The pain in the lower part of the abdomen and the lateral backache of labor are manifestations of viscerosensory referred pain appreciated in the area of skin supplied by the first lumbar nerve. The sacral backache of labor is a pain referred from one somatic nerve to others of the same spinal segments. While it is too early to be dogmatic, there seems every reason to believe that a simple and safe technic can be evolved to render childbirth painless.

**Contractions of Nonpregnant Uterus.**—Robertson made use of the intra-uterine balloon method in determining the contractions of the nonpregnant uterus. He obtained twenty records of twelve women. Of sixteen records obtained in the second half of the menstrual cycle fourteen show not only spontaneous uterine activity but also good responses to solution of posterior pituitary. In eight of these fourteen instances endometrial specimens were obtained immediately after the termination of the recording, and seven of these specimens showed secretory changes in the glandular and stromal cells. Therefore in seven cases, at least, uterine activity was recorded in the presence of an active corpus luteum and not in the absence of luteal influence as would have been the case in an anovulatory cycle. In one instance the curves were atypical. In this case two recordings were taken on the twenty-second day of

more than do normal individuals. 3. From period to period the consistency of the magnitudes of the differences between the temperatures of the two sides is high, despite the fact that the levels of temperature may be varying. 4. The variation of the magnitude of the differences between the two sides within the individual for any particular period is small. In this respect also the schizophrenic patient shows less consistency between the temperatures of symmetrically located areas than does the normal subject. 5. The degree of bilateral symmetry of skin temperatures warrants the limitation of the analysis of such data to one side of the body.

**Choline-Esterase Activity of Serums.**—Hall and Lucas describe a micromodification of the continuous titration method for the determination of the rate of hydrolysis of acetylcholine by blood serum. The choline-esterase activity is defined in terms of initial velocity of the hydrolysis. The unit chosen is the amount of enzyme necessary to liberate 1 cc. of hundredth normal acetic acid in ten minutes at  $pH$  8 and 37.5 C. The choline-esterase activity of a large number of normal and pathologic human serums has been determined. The variation within the species is from 0.9 to 3.9 units per cubic centimeter, the mode being in the interval 2.4 to 2.6. Roughly, three fourths of the bloods examined had serum activities between 1.8 and 3.2. No correlation between the choline-esterase activity of the serum and age, sex, activity, diet, heart rate or blood pressure could be found in either the normal or the pathologic group. None of the clinical conditions studied produced any characteristic change in the activity of this serum enzyme.

**Toxic Labyrinthitis of Nasopharyngeal Origin.**—O'Connor proposes to establish the intoxication caused by nasopharyngitis as an etiologic factor in toxic labyrinthitis. Twenty-three cases have been studied which displayed the typical symptoms of true labyrinthine disturbance. In none of these patients could local lesions of the labyrinth, brain, middle

ear or mastoid be demonstrated; syphilis and poisoning were conclusively ruled out. A search for a focus of infection in every case revealed, in the absence of all other significant physical changes, active subacute or chronic nasopharyngitis. The inflammatory nature of the condition was confirmed by cultures of the nasopharynx in all cases, most of which produced a heavy growth of *Streptococcus viridans*. Treatment of the nasopharyngeal vault was followed by prompt relief of symptoms. The reason for this quick response is that absorption of toxin is immediately inhibited by treatment. In an infected nasopharynx the membrane is usually found to be covered by a thin layer of mucus with a consistency similar to that of mucilage. Removal of this sheet of mucus and contraction of the lymph follicles doubtless retard the absorption of toxin long before the infecting organisms are killed. Several treatments are usually necessary before the area is entirely cleared of inflammation.

**Intrathyroid Therapy for Hyperthyroidism.**—It occurred to Postlethwaite that, if he could produce fibrous tissue in the thyroid in hyperthyroidism, beneficial results would follow. The sclerosing solution produces the minimal amount of exudative reaction after its injection, is practically painless when injected, stimulates the growth of fibrous tissue, is nontoxic and produces no systemic reaction. Since one is dealing with an endocrine gland, each patient must have a complete examination from an endocrine standpoint. The most satisfactory results have been obtained in the cases in which the course of injections into the thyroid was followed by a course of supportive endocrine therapy. The interrelationship of the thyroid, the ovaries and the pituitary during a period of ovarian insufficiency or of pituitary hypertrophy is nothing more than an attempt to meet the demand of supply by inhibition or stimulation. If by producing fibrosis in the thyroid its activity is reduced and its output lessened, it is only reasonable to assume that the system must be aided by supportive endocrine therapy to bring about a proper endocrine balance with the glands that are cooperative with the thyroid: the pituitary and the gonads. Strict asepsis must be employed. The cricoid cartilage is located; from 0.5 to 1 cm. below the cricoid is normally found the isthmus of the thyroid, then at a point from 1.5 to 2 cm. laterally, with the needle (26 gage, five-eighths inch long) directed posteriorly, the body of the gland can be injected. After puncturing the skin, the needle is pushed downward to the platysma, which usually offers slight resistance. The needle is inserted its full length through the capsule of the thyroid

**Wakening Hygiene and Exercise.**—Boigey cites three cases of sudden death during the morning exercises and explains that exercises which are appropriate for younger persons should be specially adapted for people past the age of 50 years, notably those with organic or functional disorders. After that age it is not wise to get up rapidly from bed and it is dangerous to exercise in the dorsal posture and to raise the lower extremities: this movement produces the effect of a hydrostatic blow on the walls of the cerebral blood vessels. Dizziness and even fainting may result from it. These persons should perform their exercises in the upright position, assuming an attitude which is normal for them in their waking and working hours. Certain changes take place during sleep, such as slowing of the pulse and lowering of the blood pressure. At the moment of awakening there is a rise in blood pressure, a certain degree of congestion occurs in sinuses, and the circulation of the brain becomes stronger. Exercise at this time increases the cerebral congestion, which is not equilibrated by the constrictive action of a torpid vasomotility that needs time to recover its full activity. It is therefore important for these subjects to stay in bed long enough to allow the circulation to become normal again. Persons beyond 50 years of age and all those with hypertension should then dress to avoid sudden cooling of their bodies before proceeding with their exercise. They should avoid repeated lowering of the head below the level of the belt line. Forceful flexions and extensions of the thorax have a congestive effect on the brain, do not by any means improve the abdominal circulation and may even do harm to the intestine. The author thinks that these persons should exercise between 4 and 6 p. m., as at that time of day their organic temperature, muscular strength and general vitality are at their best. The exercises should be done without much effort and speed, because their main object is to conserve the suppleness of the muscles.

Sign of Pathognomonic Detachment of Hydatid Pulmonary Cyst. Nguyen-Dinh-Hoang.—p. 2117.

**Angina Pectoris.**—Leriche and Apfeel treated a man who had been suffering for eighteen months from daily attacks of angina pectoris. The patient had diabetes and had been suffering for three months from Wallenberg's syndrome. The syndrome, the result of an obliteration of the inferior cerebellar artery, is characterized by a transient hemiplegia, hemianesthesia and pains on the side opposite the lesion. There were also atactic symptoms and a tendency to fall to one side. Added to this was paralysis of the muscles of deglutition, of the soft palate and of the vocal cords. After a stellate infiltration and in an attempt to bring about a favorable reaction on the medullary and the coronary circulation, they resected the stellate ganglion and the roots of the vertebral nerve. Two days after the operation the patient lost his bodily deviations and his ataxia. All his movements became easy, and no sign of cerebellar deficiency remained. At the end of three weeks the patient had a hypostolic attack and most of his medullary symptoms reappeared and lasted for a few weeks. But he gradually recuperated and three months after the operation the angina, vertigo and diplopia as well as other cerebellar symptoms had completely vanished, except the painful anesthesia of the chest and the right lower extremity. After seven months the recuperation was still better, even in the right leg. Although

the future of such patients is uncertain, the fact remains that in this case the intervention surpassed all hope. This result shows that, in vascular syndromes of the brain with definite symptoms of irreversible deficiencies, a sympathectomy may be of great benefit. It is further certain that in their case first the stellate infiltration and then the stellectomy (roots of the vertebral nerve originating from the superior pole of the stellate ganglion) have considerably modified the outcome.

\*Is Resection of Splanchnic Nerves Justified in Treatment of Permanent Essential Arterial Hypertension? H. Hermann and L. Sabadini.—p. 41.

Bacterioserologic Methods in Tracing of Persons Who Had Been the Cause of Puerperal Fever. J. Drbohlav.—p. 44.

**Resection of Splanchnic Nerves in Treatment of Hypertension.**—Hermann and Sabadini state that most of the methods advocated for the treatment of permanent essential hypertension are difficult of execution and for this reason they have limited themselves to reaction of the splanchnic and sympathetic nerves. Essential hypertension may be permanent or paroxysmal. Paroxysmal hypertension is often accompanied by a medullary adrenal tumor having the characteristics of a benign adenoma. This tumor is at times juxta-adrenal of a paraganglionic type. This is quite natural when the sympathetic origin of the adrenal medulla is considered. Both are derived from the ectoderm. The current surgical practice is complete adrenalectomy. Quite different is the case in permanent essential hypertension, in which the lesions are much less constant. The hypertrophic gland shows a medullary hyperplasia and increased hormonal contents. It is much too hazardous to assail the gland directly. It is more advantageous to dry out the secretion either by denervation or by devascularization, or better still by resecting its secretory nerve, the splanchnic nerve. The latter method is superior because it cuts the vasoconstrictor nerves, thus producing vasodilatation. The most frequently employed method is the posterior, laterovertebral, subserous (subpleural or subperitoneal). It may be high central or low. Pende has recommended anesthesia of the nerve with procaine hydrochloride in hypertension crises, to be followed, in patients not fit to be operated on, by unilateral or bilateral alcoholization of the nerve. But the splanchnic nerve does not alone innervate the adrenal capsule. There are posterior filaments emanating from the terminal trifurcation of the nerve and from the adrenal ganglion. It also receives branches from the diaphragmatic, renal and solar plexuses. Besides, there are often anastomoses between the right and the left splanchnic nerves. All this shows a multiplicity of origins, but only in man. In the dog, every adrenal gland gets its secretory nerves solely from the homolateral splanchnic nerve. All these as well as the physiologic and clinical considerations lead the authors to the realization that the pathogenesis of permanent essential hypertension is not sufficiently known to justify conclusions as to its surgical treatment. The facts given by the authors seem to be in accord with certain therapeutic results. But in order to confirm them further, stricter scientific observations are suggested. In only a few cases has splanchnicectomy greatly improved a state of hypertension which has otherwise resisted all other treatment. They especially underscore the fact that the main body of the splanchnic nerve consists of centrifugal and centripetal conductors. On cutting them one interrupts not only the vasoconstrictor and adrenal secretory fibers but also the sensitive paths used by the reflexes originating in the abdominal viscera.

**Treatment for Trichomonas Vaginitis.**—Zener found by experimentation and direct observation that an ointment containing 6.6 per cent vioform with a melting point slightly above body temperature (from 103 to 105 F.) would spread over the entire vaginal mucosa. Traces were present in the vagina after seventy-two hours. The ointment used is hygroscopic. As yet the ideal base for the ointment has not been found. The patients are treated on alternate days. No treatments are given during the menses, but the patient is instructed to douche twice daily with 2 quarts of warm 25 per cent saline solution. When the vagina is thoroughly cleaned, one-half ounce of the ointment, containing 0.75 Gm. of vioform, is instilled high in the vaginal vault. A large glass syringe with a long nozzle is used for this purpose. The patient is instructed not to take douches, except as directed during her menses. Since this method of treatment has been adopted, thirty-eight cases of trichomonas vaginitis have been treated. Nine patients have passed through four menstrual periods without recurrence, nine through three, nine through two and eleven patients are under treatment with definite improvement.

**Hematologic Studies on Malaria in Puerto Rico.**—Rodríguez Molina and Oliver González performed hematologic studies on 100 individuals suffering from malaria, 83 per cent of whom presented the chronic and 17 per cent the acute type of case. Though 70 per cent of cases gave red cell counts below four million per cubic millimeter, only 10 per cent showed hemoglobins below 10.2 Gm. (70 per cent); the degree of anemia for the entire group was considered slight, the mean red cell count being 3.95 million and the mean hemoglobin 12.3 Gm. (85 per cent). Examination of stained smears did not show much evidence of active blood formation. A macrocytic anemia was found in 34 per cent of the patients, normocytic anemia in 37, simple microcytic anemia in 16 and hypochromic anemia in 13 per cent. Characteristic leukopenia was detected in only thirty-five cases. Schilling hemograms showed a degenerative shift in the granular leukocytes. No remarkable changes were observed in the platelets or in the sedimentation rate of the red corpuscles. Racial or acquired resistance to the disease and a high animal protein content in the dietary of the population studied are believed to be important factors responsible for the slight degree of anemia encountered. It is inferred from this study that the blood picture in malaria in Puerto Rico is not in itself of diagnostic value apart from the finding of the causative organism.

**Treatment of Chronic Catarrhal Deafness.**—From 1929 to 1935 inclusive O'Brien treated 140 patients by roentgen irradiation: seventy-three were improved as to hearing and tinnitus; the condition in sixty-five was unchanged and it was made worse in two. Of the improved group, sixty-seven had nine treatments to each ear and six received only eight treatments; nine treatments have been designated as the acceptable course or cycle. Accepting a cycle of nine treatments as the optimum, approximately 78 per cent who received it were benefited. No patient has been followed less than a year, the majority for more than three years and some as long as five years. The much abused tonsil did not seem to play a direct part in the beneficial outcome of irradiation of these cases. The x-ray factors employed were 145 kilovolts, 5 milliamperes, 0.25 mm. of copper and 1 mm. of aluminum filter at a distance of 50 cm. over a field 15 by 15 cm.; the exposure lasted five minutes, about 90 roentgens in air being given to each ear-field at one sitting and repeated at weekly intervals for nine treatments. A large field with the hypotenuse of the two right-angles extending from the nares to the mastoid tip was chosen deliberately to include the nasopharynx, the course of the eustachian tube and the mastoid and ear structures because of the accepted relationship of lymphadenoid tissue and infection

and a pleural reaction with formation of exudates or transudates on the contralateral side. The authors give the sign the name of both discoverers: Koranyi-Grocco's sign.

**Operative Treatment of Puerperal Sepsis.**—According to Heynemann, the main consideration in the treatment of puerperal sepsis is the removal of the septic focus through exposure and drainage or through extirpation of a suppurating organ. The localization of such foci constitutes the real problem in the treatment of puerperal sepsis. Vein ligation is seldom indicated. It is to be considered only in cases in which sepsis is of thrombophlebitic origin. The operation of vein ligation is technically not difficult. The difficulty lies in the uncertainty of its indications. Hysterectomy is not indicated in the treatment of sepsis. The only exceptions to this rule are the gas bacillus infection of the uterine musculature and, occasionally, an infected myoma or abscess of the uterine wall in the course of the puerperium. These complications, however, are unusual. Hysterectomy is likewise to be considered in certain cases of life threatening hemorrhages developing in the course of a febrile puerperium or due to retained placental tissue.

**Effect of Cod Liver Oil Dressings.**—Kümmell and Jensen state that wounds treated with cod liver oil ointment heal more quickly. Wounds irrigated with cod liver oil ointment likewise displayed an increased tendency to healing. The favorable effect was evident at a distance away from the irrigated area. The authors found in their experiments that the cod liver oil alone did not exhibit a necrolytic effect. However, necrolysis was definitely increased in the presence of pus. They did not observe any effect of cod liver oil dressings on the growth of bacteria in rabbits. The effect of the cod liver oil on the toxicity of pus was quite evident in animal experiment from the fact that the mortality was reduced 30 per cent.

**Cystine Disease During Early Childhood.**—Beumer and Wepler direct attention to extensive cystine deposits in the organs during early childhood, pointing out that this condition was first described in 1903 and again in 1924. The condition was never correctly diagnosed during life, but the author thinks that a knowledge of the characteristic clinical picture ought to make this possible. He reports the case of a child that came under his observation first at the age of 2 months on account of otitis media. At that time the development of the child seemed normal, but at the age of 10 months the child was in a condition of severe atrophy although it had been breast fed for nine months. The constant loss of weight had begun after an attack of measles. The child was kept under clinical observation for four months, but there was practically no change, except a slight increase in weight, which was lost again almost immediately after the child left the hospital. The urine always contained albumin and sugar. On the basis of the clinical aspects, the case was diagnosed as renal diabetes and renal dwarfism. The child died at the age of 18 months and the necropsy corroborated the clinical assumption of renal disease. Examination of spleen, liver, kidneys and thymus

revealed large masses of a substance that was identified as cystine. The histologic changes were severest in the kidneys. A comparison of this case with those reported in the literature reveals considerable similarity. Following a discussion of recent observations on the cystine metabolism, the authors assume that the renal disease is the result of the nephrotoxic action of cystine.

**Gonadotropic Action of Extracts of Adrenal Cortex.**—Hoffmann describes animal tests which prove that the adrenal cortex contains a gonadotropic substance which differs from the surviving hormone of the cortex by its insolubility in lipid solvents and which thus can be differentiated from the surviving hormone. This gonadotropic substance stimulates the ovaries, as is indicated by an enlargement of the organ and by an increased follicular maturation with luteinization of the theca interna. If the gonadotropic substance of the cortex is given together with small doses of the gonadotropic substance of the anterior hypophysis, the enlargement of the ovaries is more pronounced and corpora lutea are formed. Thus the action of the gonadotropic substance of the adrenal cortex corresponds largely to the well known actions of the gonadotropic substance of the anterior hypophysis. Regarding the mode of action of the gonadotropic substance of the adrenal cortex, the author says that the rapidity of the action seems to indicate a direct stimulation of the gonads; he considers an indirect action by way of the anterior pituitary unlikely, although the definite proof for this has yet to be furnished by suitable tests on hypophysectomized animals.

**Thoracic Lead in Detection of Cardiac Lesions.**—Kisch demonstrates that the thoracic lead "from the left leg to the region of absolute cardiac dullness" may disclose the presence of a myocardial lesion in cases in which the leads from the extremities as well as the clinical symptoms fail to indicate such a defect.

\*Alimentary Dilatation of Aorta. S. Kreuzfuchs.—p. 52.  
Experiences with Combined Administration of Calcium and Quinine in Obstetrics. P. Busch.—p. 52.

**Diameter of Erythrocytes in Huntington's Chorea.**—Von der Mark examined twenty-four cases of Huntington's chorea and detected an enlarged erythrocytic diameter in twenty-one. The author points out that this high incidence of an enlarged erythrocytic diameter suggests the possibility of a connection between Huntington's chorea and hepatic impairment. However, the literature reports only one case with indications of such a connection. The author states further than the enlargement of the erythrocytic diameter in Huntington's chorea might suggest a connection with an impairment of the bone marrow. On the other hand, he thinks that it might merely be a concurrence and not a relationship.

**Alimentary Dilatation of Aorta.**—In studies on the width of the aorta, Kreuzfuchs observed considerable degrees of dilatation in obese persons beyond the age of 35. He found that the development of the musculature causes no dilatation of the aorta; on the contrary, in athletes he often noticed a comparatively narrow aorta. However, fat tissues have a decided influence on the width of the aorta. In view of the fact that the

mately adherent to it and growing from it was the large crystalline calculus. On this calcium plaque a secondary deposit of a definitely different chemical character has been formed; that is, a definite undermining of the edge of the calcium plaque by crystalline deposits and growth of stone. This strongly suggests that, as the stone grows, it gradually encases the calcium plaque by undermining its edges, and, when the stone breaks free, the plaque is torn from its papillary bed and goes away with the calculus. It is the author's belief that, as the secondary deposit, or true calculus, grows, crystallization at the edges of the original plaque gradually undermine the plaque and that the calculus, when it gains its freedom, does so by tearing out the plaque from the wall of the papilla.

**Cruciate Ligament Injuries.**—Cubbins and his co-workers summarize their cases of dislocations of the knee joint in which there have been ruptures of one or both cruciate ligaments. They have had nine cases of double, four of anterior and two of posterior cruciate ligament injuries. In two cases of complete unreduced dislocations of the knee joint the limbs were shortened and recurved, with a total loss of the use of the limbs. After reduction, the tibial head could be carried in any direction around the femoral condyles and any type of dislocation could be reproduced. In three patients with complete rupture of all the ligaments of the knee joint observed immediately following the injury there was a total loss of function, marked swelling, discoloration and exquisite tenderness over the entire joint. Of these six completely dislocated knee joints there have been four excellent recoveries, one fair and one untreated, a failure. In four cases of old dislocations of the knee joint diagnosed as ruptured cruciate ligaments of the knee, the symptoms were loss of stability or function, the limb breaking down anteriorly or wobbling in a lateral direction; pain or tenderness not marked; either a slight or a negative amount of fluid; no stiffness or limitation; marked passive mobility at all times; very extensive mobility when the patient is put under anesthesia—almost  $2\frac{1}{2}$  inches of motion in the anteroposterior direction—and a lateral or medial deviation of the extended leg of from 30 to 50 degrees. The authors have observed no trace of the injured cruciate ligaments remaining in any of the injured joints operated on three months or more after the injury has been sustained, either in the single or in the double type of cruciate ligament injury. In none of the four cases of complete rupture of the cruciate ligaments were the menisci injured or displaced. In the two old injuries to the posterior cruciates both menisci were normal. There were no detached pieces of cartilage, bone or ligament in the joint cavity of any old case. In only one case was there a lesion in the cartilage of the femoral condyles. The ability of the knee joint to stabilize itself if immobilized is remarkable. In their new operative procedure the authors make the limb bloodless with a Martin band and a tourniquet on the upper portion of the thigh. An incision 13 inches long is used. It extends from 10 inches up the thigh down and around the head of the fibula; then a strip of fascia lata 1 inch wide is removed and dissected down to where it has a loose attachment on the lateral condyle of the femur. Another strip posterior to it and of about the same width is then dissected from its base down to where it curves forward and is attached to the head of the tibia. The knee joint itself is then opened. The incision extends down through the skin, through the lateral portion of the vastus medialis, through the fascia and synovia of the knee joint, until the suprapatellar space is exposed, and then down on the head of the tibia for a distance of 3 inches. As this incision is made it can be carried in through the synovial membrane and periosteum of the femur above the condyle about  $2\frac{1}{2}$  inches, and the periosteum and synovia elevated to a width of about three-fourths inch. On the head of the tibia a like incision is made down through the periosteum, and the periosteum is dissected up about three-fourths inch. Holes are drilled in these condyles for the placement of the new ligaments, which are twisted slightly. Curved alligator forceps can be passed outward through this lateral condyle to grasp the new ligament and pull it through into the knee joint. The new posterior ligament is carried through the fascia, covering the head of the fibula so that it will have a firm point of fixation, and pushed up beneath the lateral head of the gastrocnemius, the peroneal nerve and the popliteus tendon, through the posterior capsule into the knee joint. It is grasped with forceps as it

comes through into the joint, pulled forward and, with alligator forceps, pulled up through the medial condyle of the femur. The new anterior cruciate is now pulled down through the head of the tibia, the ligaments are drawn so that they are firm but not tight, with the limb flexed at an angle of from 25 to 35 degrees, and then they are sutured into their osteoperiosteal beds. The wound in the lateral surface of the thigh and leg is closed with clips. In closing the anterior wound, one should pick up and ligate any vessels with open mouths. Then the capsule is closed with continuous catgut suture, one from below up, and one from above down, a space being left between. The hemorrhage that will certainly follow this procedure can escape through the opening in this capsule, and the skin is closed loosely with clips so that there will be no accumulation of fluid in the knee joint. In the two operations for the repair of the posterior cruciate ligament the same method has been used as just detailed for the posterior cruciate.

**Pathways and Production of Pain.**—Hamilton believes that the most adequate of existent theories regarding the production of pain is that of Lewis, which supposes the accumulation in the tissues of a pain substance produced by metabolism. However excited, impulses follow pain fibers, which pass from the viscera through sympathetic trunks but not through the vagus nerve. They are known to result in referred pain. Referred pain, sweating, hyperalgesia and temperature changes are valuable indexes in localizing visceral lesions, in recognizing psychotic cases and in exposing malingering. Pain may also be conveyed from the parietal mesenteries in a manner indistinguishable from visceral pain. In the limbs, individual pain fibers are periarterial for only short distances before passing from blood vessels to nerve trunks. The ideal surgical site for the certain removal of these pathways is at the sympathetic ganglions or posterior nerve roots, since the fibers tend to be more scattered whenever they are peripheral and central to the ganglions.

lation tissue of the focus, with subsequent rarefaction of the surrounding spongy tissue. The two latter phenomena are accompanied by softening processes (appearance of leukocytes within the old caseosis and autolytic dissolution) of the "primary" foci. Tuberculosis of the tubular bones and joints in children after 5 years of age is mostly due to progressive development or reactivation of different primary osseous foci. The exacerbation of such foci in the adult state probably constitutes the basis of osteo-articular tuberculous disturbances (trochanteritis, coxitis) in this age. The cause of such exacerbations of the primary foci remains unknown.

#### Relation of Hypophysis to Stomach and Bone Marrow.

—In five patients with signs of insufficiency of the anterior pituitary, Snapper observed a complete gastric achylia. In one patient the gastric achylia produced a completely developed pernicious anemia and in another a hyperchromic blood picture. In the other three patients the blood showed no abnormalities, but there were more or less severe signs of systemic disease of the spinal cord. The author thinks that a connection may be assumed between insufficiency of the anterior pituitary and gastric achylia, which later may cause changes in the blood or lesions of the spinal cord.

**Diabetes Mellitus and Exophthalmic Goiter.**—Labbé directs attention to the concurrence of exophthalmic goiter and diabetes mellitus. After reviewing the literature on this problem, citing among others several of his own earlier reports, he points out that the association of the two diseases is of a frequency that cannot be explained as mere coincidence and must be regarded as the result of an endocrine relationship. Usually the exophthalmic goiter appears first and the diabetes develops later; however, in exceptional cases the diabetes may appear first. The simultaneous appearance of the two diseases suggested a thyroid diabetes, dependent on a disturbance in the thyroid glycoregulation and differing from the ordinary pancreatic diabetes. Observations on the therapy of such cases indicate that the treatment of the thyroid disease reduces the severity of the diabetes but does not cure it, doubtless because it counteracts only the hyperthyroid glycoregulatory disorder but not the pancreatic insufficiency.

**Bacteremia and Bacterial Localization.**—Van der Hoeden describes five cases in which, by local trauma, organisms pre-existing in the damaged region were carried into the blood stream. Endocarditis lenta was caused by *Streptococcus viridans* after tooth extraction; paratyphoid developed after cholecystectomy; *Bacillus proteus* bacteremia resulted from operation in infected tissue; fever and rigor were caused by streptococci after catheterism, and another case of *proteus* bacteremia occurred after wound treatment. Further, the author cites cases of bacterial localization; for instance, *Streptococcus viridans* on congenitally defective aortic cusps, tubercle bacilli after mechanical trauma, and pneumococci at the site of injection after pneumonia. The author concludes that these clinical observations provide more insight into the mechanism of bacterial infections and demonstrate the risk of even minor interventions.

**Fever Therapy of Intractable Neuralgias.**—Klinkert reports a number of cases of refractory neuralgia which he cured by means of fever therapy. He induced the fever with a preparation consisting of the proteins of nonpathogenic bacteria. He thinks that the cure was brought about by the acceleration of the blood and lymph stream during the artificial fever. He recommends artificial fever therapy for such cases of neuralgia in which physical methods are unsuccessful or cannot be employed for social reasons.

\*Biologic Action of Roentgen Rays on *Bacterium Coli*. E. Unonius.—p. 999.

**Recent Primary Tuberculous Focus in Lung.**—Wallgren says that Verse's investigations together with Rossle's and his personal observations indicate that the noncalcified primary focus in the lung is not generally demonstrable in the roentgenogram, even though the focus may be the size of a hazelnut. In most cases of recent infection with pulmonary tuberculosis a primary focus is present, but it does not absorb enough roentgen rays to become visible. In forty-one student nurses the tuberculin test was negative at the start of training. When in the course of their hospital work the reaction became positive, roentgen examination was made; in only one case was a shadow in the lung parenchyma demonstrated which might be due to a primary focus; in two there were shadows of doubtful origin, in thirty-eight the results were negative. Three other cases are described in which recent tuberculous foci in the lungs were confirmed at necropsy but had not been demonstrable roentgenologically during life.

**Relation Between Rickets and Mental Deficiency.**—From somatic and psychologic examination of 375 premature children ranging in age from 7 to 15 years, Brander found that in the group with graver traces of earlier rickets there was greater frequency of feeble-mindedness, cases bordering on feeble-mindedness and ordinary stupidity, while the number of normal and talented children was correspondingly less. Since the defects in intelligence were of relatively mild degree, he concludes that rickets can hardly be of practical significance in the etiology of oligophrenia. There was no evidence for or against rickets as leading to lasting mental deficiency of milder degree, but both rickets and defective mental development might have the same cause, as, for example, premature birth. It seems to the author fairly certain that mental deficiency in itself is something which promotes the origin of rickets.

**Biologic Action of Roentgen Rays on *Colion Bacillus*.**—Surface cultures of *colion bacillus* were irradiated with hard rays in a dose of 500 or with soft rays in a dose of 2,000 roentgens. New cultures were again made from the mature colonies and the same dose was again given. This procedure was repeated until the bacteria in the experiment with hard rays had received ten doses and those in the experiment with soft rays twenty doses. On examination of the irradiated bacteria, Unonius found no change with regard to grape, milk and cane sugar, mannite and salicin, formation of indole, agglutinability, movement and  $pH$  tolerance.

Bronchial Asthma: Additional Fatal Case. J. V. Jørgensen.—p. 1350.

**Cause of Fog Catastrophe in Meuse Valley in 1930.**—Roholm describes this mysterious fog catastrophe near Liège, Belgium, which caused several thousand cases of disease and sixty deaths. He reviews acute and chronic fluorine intoxication and analyzes the details of the catastrophe, showing that there was probably an acute fluorine intoxication. He asserts that, of the twenty-seven factories in the region, fifteen belonged to branches of industry which either use raw materials containing fluorine (superphosphate factories, zinc works) or add fluorine combinations to raw materials (steel work, iron foundries, glass works) with the possibility of giving off gaseous fluorine combinations ( $SiF_4$ , HF) in the smoke from the chimneys. Special climatic and topographic conditions played a part in the development of the catastrophe. Since the toxicity of fluorine combinations is considerable and well known in industry, factories that give off gaseous fluorine combinations should be required effectively to remove these substances from the chimney smoke.

two successive cycles and on both occasions, although there was marked spontaneous activity, no rise of muscle tone or increase in the contractions resulted from the injection of solution of posterior pituitary. No clue to the cause of this refractoriness was revealed either by palpation of the pelvic organs or by microscopic examination of the endometrium. In another instance, although the menstrual dates placed the day of the observation of the uterine behavior as the seventeenth of the cycle, and it was known that the intermenstrual periods usually lasted less than twenty-eight days, the endometrium was proliferative in type and not, as was expected, secretory. This case demonstrates well the importance of endometrial examination as a means of obtaining collateral evidence of ovarian function, especially as regards the recognition of an anovulatory cycle.

**Lymphadenosis Complicated by Tuberculosis.**—In the case of chronic lymphadenosis that Weber and Schlüter report the permanence of the leukopenia and granulocytopenia was a striking clinical feature. In the twenty-seven differential leukocyte counts taken at the hospital during the patient's life the average percentage of lymphocytes was 81, while the total leukocyte count averaged 3,407. After the patient's death the typical interacinous lymphocytic infiltration of the liver seen by microscopic examination, as in cases of lymphatic leukemia, was by itself sufficient to prove the correctness of the lymphadenosis explanation of the clinical features. But the miliary tuberculous process at the end was not suspected before the postmortem examination. The presence of some latent, quiescent tuberculous focus may have tended to make the lymphadenosis one of the aleukemic kind and hindered its active progress, though afterward an acute miliary resuscitation of the tuberculous process caused the death of the patient.

The Registration of Medical Specialists. E. L. Ferguson.—p. 838.

**Treatment of Pneumonia.**—Kaplan's technic consists in strapping the chest with an elastic adhesive bandage applied from the normal side across the front of the chest and around the affected side to the back. The necessary stretch is applied to the bandage until the patient feels relief of pain in breathing. The distal end is then attached to the normal side. The best procedure is to apply the upper band high up into the axilla. The lower band is applied in the same manner but incorporates the eighth, ninth and tenth ribs and upper portion of the rectus muscle. The majority of patients complain of abdominal pain due to the added strain exerted on the extraordinary muscles of respiration when coughing. A third band is applied midway

between the first two or over any painful area of the affected side. When both lungs are affected the strapping is applied to form a complete hoop. Relief is obtained instantaneously. The agitated clenching of teeth and anxious expression is replaced by peaceful, painless respirations. The pulse improves and the patient is able to rest. The extremities are wrapped in elastic crape bandages in order to assist in combating the capillary dilatation. In this manner the circulating volume of blood is increased and thereby tends to stave off heart failure. Whenever the temperature is above 102 F., four-hourly doses of from 0.25 to 1 Gm. of quinine urea in 5 cc. of distilled water is administered. This is continued until three doses have been given. Potassium iodine and creosote are both excellent drugs. Potassium iodine acts as a bactericide and liquefies the tenacious secretions which increase the coughing. Creosote is antiseptic and diminishes secretions by allaying irritation. Digitalis in pneumonia uncomplicated by heart disease is contraindicated. Ten cases are described in which the foregoing treatment has proved successful.

Simple Laboratory Method for Desiccation of Serum and Other Protein Solutions. P. Hartley.—p. 735.

**Proposed Standard for Gas Gangrene Antitoxin (Histolyticus).**—For the purpose of the international enquiry, according to Jensen, a dry histolyticus antitoxin prepared by the Statens Serum Institut in a glycerol solution containing 20 provisional units per cubic centimeter was distributed, together with a preparation of histolyticus antitoxin of unstated potency, the experts concerned being invited to determine the potency of the latter preparation in terms of the provisional unit suggested. To facilitate the work, a preparation of dry stable histolyticus toxin was supplied to all participants. The conclusions drawn are that gas gangrene antitoxin (histolyticus) can be assayed with a high degree of accuracy, that dry, stable preparations of gas gangrene antitoxin (histolyticus) can be prepared and assayed in terms of an accepted standard preparation, and that accurately standardized solutions can be prepared which are suitable for purposes of biologic assay. It is recommended that the Permanent Commission on Biological Standardisation should accept the dry stable preparation of gas gangrene antitoxin (histolyticus) prepared at the Statens Serum Institut, Copenhagen, as the international standard for this antitoxin, and that the commission should define a unit, in terms of this standard preparation, for adoption for international use.

**Operation and Result.**—December 4 a typical acoustic tumor was totally removed (fig. 2). A unilateral cerebellar approach was used. The tumor weighed 13.6 Gm. The patient made an uneventful recovery and has remained well. There have been no subsequent dizzy attacks to Oct. 1, 1936.

**CASE 3.—History.**—M. McG., a man, aged 55, admitted Nov. 17 and discharged Dec. 1, 1935, complained of pain in the back of the head, dizziness and vomiting. The diagnosis was angioma with a large cyst filling the left cerebellopontile

The cyst extended as far forward as the fifth nerve, which was pushed against the brain stem. A solid mural angioma, the size of a hazel nut (fig. 3), located to the left tonsil of the cerebellum, was completely excised. The patient made an uneventful recovery and has been well to date. When seen in July 1936 there had been no postoperative attack of dizziness.

**CASE 4.—History.**—M. G. M., a girl, aged 15 years, admitted Nov. 5 and discharged Nov. 24, 1934, complained of dizziness, nausea, vomiting, tinnitus and deafness in the right ear. The diagnosis was Ménière's disease caused by strangulation of the right auditory nerve by an arterial loop (fig. 4).

The family history was negative. The past history was negative except for otitis media in the left ear in infancy.

Ten and one-half years before, when the patient was 4½ years of age, she had her first attack of nausea and vomiting and is said to have been unconscious for several minutes. There were no associated clonic movements, although she is said to have been rigid. Nausea, vomiting and headache persisted for several days. Within several months she had three similar attacks but was well between them. A routine examination disclosed that she was totally deaf in the right ear.

Nine years before the present admission I explored the cerebellar region, thinking she probably had a cerebellar tumor, and found what appeared to be vascular irregularities in both lateral recesses. Three months later she had a similar attack lasting several days. During the next year and a half she was quite well and her parents thought she had entirely recovered. However, during the next two years she had many spells of vertigo, tinnitus, nausea and vomiting that lasted for days and even weeks. Vertigo was the most distressing symptom. Then followed another free interval of one year without attacks. Again the attacks of vertigo recurred, but without stupor or loss of consciousness. There then followed another period of freedom lasting more than a year and a half, but again the attacks returned a year ago. There were periods of constant vertigo interspersed with short attacks, which came at frequent intervals. These attacks were described as follows: Preceding the onset of vertigo by several hours or even several days there was increasingly loud tinnitus in both ears; she would then become progressively deaf in the left ear (the right being totally deaf since childhood) so that her mother would have to shout to her in order to make her hear at all. She then complained of her skin being sensitive, especially over both sides of her face, and her arms and legs tingled. These premonitory symptoms were invariably followed by vertigo, which was usually accompanied by vomiting and extreme nausea. Objects danced and rotated, but in which direction

Fig. 1.—Aneurysm of the basilar artery pressing on the eighth nerve and causing Ménière's disease.

angle. The family and past histories were negative. Four years before, the patient had a sudden attack of severe vertigo in which objects rotated constantly. The attack, which lasted an hour, was accompanied by vomiting and he had to lie down. There was neither tinnitus nor loss of hearing. After the attack he felt perfectly well again until a second similar one four months later. Immediately following the second attack he was able to go to work. A third attack occurred three years later. During August 1935 severe intermittent pain developed in the occipital region, more on the left side. About this time diminution in the hearing of the left ear was first noticed. But little hearing now remained. There had been intermittent tinnitus (noise like a cricket) in the left ear. During the past several weeks he had had attacks of vomiting without nausea; he had been so unsteady on his feet that his friends have commented on his staggering gait. Six months ago he gave up work because he was fearful of falling. He has lost 30 pounds (13.6 Kg.) during the past six months.

**Examination.**—The patient was undernourished and looked ill. The positive changes were bilateral papilledema of 3 diopters in each eye, horizontal nystagmus to the left, staggering gait, and positive Romberg sign with falling to the left. The deep reflexes increased on both sides. Hearing in the left ear was markedly reduced and normal on the right. The caloric test was negative on both sides.

The diagnosis was tumor in the left cerebellopontile angle. **Operation and Result.**—November 19, a unilateral cerebellar approach was made on the left side. A large bulging cyst filled the cerebellopontile angle. A tremendous amount of cystic fluid was evacuated when the cystic lining was removed. One could then see the excavated glistening white brain stem. All the nerves in the angle stood out clearly. The eighth nerve ran directly through the cyst and was definitely elongated.

Fig. 2.—Acoustic tumor causing typical Ménière attacks.

she was unable to say. During the attacks she would lie perfectly still, usually keeping her eyes open. Her vision was blurred at times but there was no diplopia. There was generalized headache throughout the seizure. As the attacks subsided the tinnitus decreased and her hearing improved. Many of the seizures occurred at night, causing her to awaken. She would frequently dream of falling. The tinnitus was apparently about equal in the two ears and was described as a roaring sound. She had never fallen in an attack, because there was ample warning that one was developing. Because of the fre-

nancy from the normal figure of 47 mg. per hundred cubic centimeters of blood to 49 mg. and decreases slowly after the second month to reach 42.5 mg. by the ninth month. Immediately after delivery and during the puerperium, the amount of total iron in the blood increases again to normal figures. Coincidentally with the increase of iron during the first two months there is diminution of the number of erythrocytes and of the amount of hemoglobin in the blood, which continues slowly after the third month of pregnancy and reaches the lower figures by the ninth month. The diminution of the amount of total iron in the blood which takes place during the last six months of pregnancy is not proportional to that of the number of erythrocytes and the amount of hemoglobin during the same period of pregnancy. In the course of normal pregnancy the amount of total iron in the blood diminishes, but that of relative iron increases. The relative iron increase is due to the presence of iron in transit and other types of iron, not combined with hemoglobin, in the blood. This statement is proved by the fact that the ratios iron:hemoglobin and iron:erythrocytes are increased.

### Policlinico, Rome

44: 1-60 (Jan. 15) 1937. Surgical Section

- Primary Atrophy of Kidney Without Hydronephrosis Following Ureteral Ligation: Experiments. F. De Victoris-Medori.—p. 1.  
Volkmann's Ischemic Contracture: Surgical Treatment. G. Montemartini.—p. 12.  
Embolism of Pulmonary Artery and of Arteries of Limbs. V. Palumbo.—p. 19.  
\*Biliary Peritonitis Without Perforation of Biliary Tract. G. Scoppetta.—p. 39.

**Biliary Peritonitis Without Perforation.**—Scoppetta says that the pathologic picture of biliary peritonitis without perforation of the gallbladder or of a segment of the biliary tract is that of acute peritonitis. There is acute abdominal pain all over the abdomen, especially located in the right iliac fossa. There is also contracture of the abdominal wall, especially of the right side, and general symptoms of an acute abdominal condition. The diagnosis of biliary peritonitis is difficult. The treatment is surgical and necessarily immediate. The selection of the operation is governed by the condition of the patient. In general, the operation of choice is cholecystectomy. Frequently the condition coexists with calculosis. In rare cases it develops in persons who had cholecystectomy performed. The bile or bile fluid in varying amount and of varying quality, and containing pancreatic ferments, is found free in the peritoneum. Examination of the gallbladder removed by cholecystectomy shows that the structure is enlarged, edematous and with thinned walls, especially at the fundus. The thinness seems to be near perforation. On macroscopic examination the mucous membrane is frequently found to be hemorrhagic and ulcerated. Microscopic examination shows absence of the epithelium of the mucosa, fibromuscular destruction and infiltration, formation of microscopic abscesses, changes in the blood vessels and inflammation and necrosis of the walls of the gallbladder, most intense at the areas of thinness of the structure. Macroscopic changes can be observed also in the omentum, the pancreas and certain intestinal segments. The author reviews the various theories on the pathogenesis of biliary peritonitis without perforation and reports a case in which the patient recovered after cholecystectomy. The general picture of the disease and the macroscopic and histologic signs of the removed gallbladder of the author's case corresponded to those previously described.

**Leukocyte Hemograms and Sedimentation Speed in Infantile Tuberculosis.**—Ferreira and his collaborators studied the leukocyte hemograms and the sedimentation speed of the erythrocytes in children suffering from different forms of tuberculosis in evolution. A general model of a hemogram of changes of the leukocytes in tuberculosis in children cannot be made because the changes are different in all cases. There

is leukocytosis and neutrophilia in nearly all cases and a deviation of the ratio of segmented and nonsegmented neutrophils in all cases. Monocytes are of no diagnostic value because of their irregular behavior. The sedimentation speed is increased in the blood of tuberculous children. This increase depends on a diminished resistance of the patient and is not related to the localization and phase of evolution of tuberculosis. According to the authors, leukocyte hemograms and the sedimentation speed are complementary procedures to the tests commonly used in diagnosis of tuberculosis in children. Their value is that of orientation and the results have to be verified by those of clinical and roentgen examinations of the patient as well as by laboratory tests.

**Test of Cutaneous Sensitivity to Gold Salts in Pulmonary Tuberculosis.**—Raimondi and D'Amato state that in 1935 Chiucini and Aradas tested the cutaneous sensitivity to gold salts as a guide to indication for gold treatment in pulmonary tuberculosis. The test consisted in the subcutaneous injection of 0.1 cc. of a 1 per thousand solution of a gold preparation (phosphocrysol). A positive reaction showed the appearance of an area of more or less intense redness around the point of injection. The reaction developed shortly after performance of the injection and was sometimes associated with fever. The red spot lasted for a few days and then disappeared. According to the originators of the test, a positive reaction showed intolerance to gold treatment and, when tolerated, the results of the treatment on pulmonary tuberculosis were unsatisfactory, while a negative reaction indicated good tolerance and good response of the patient to gold treatment. Raimondi and D'Amato made the test on a group of patients suffering from different forms of pulmonary tuberculosis for verification of the value of the test. They found that 50 per cent of the persons with negative reactions presented intolerance to the treatment and 69 per cent of those with positive reactions had good tolerance. The results of the treatment have nothing to do with the reactions, positive or negative. They depend on the form and evolutionary phase of the pulmonary tuberculosis. The authors state that the test of cutaneous sensitivity is of no use as a guide to indications for gold treatment in pulmonary tuberculosis.

**Semeiologic Value of Grocco's Sign.**—Piaggio Blanco and his collaborators state that Grocco's sign in pleurisy is rare (a frequency of 6.5 per cent of the cases). It appears only in certain cases of abundant pleurisy. Fluid is obtained by puncturing the area of dullness, whereas one fails to obtain any by puncturing the corresponding area in which there is no dullness. This fact and the results of an injection of 0.05 Gm. of methylene blue at the area of contralateral dullness after removal of fluid show that the appearance of Grocco's sign is due to contralateral presence of exudative or transudative pleuritis. Other pathogenic theories on the significance of Grocco's sign are erroneous. The simultaneous appearance of pleurisy and of Grocco's sign in cases in which the latter makes its appearance is the result of simultaneous development in the posterior costomediastinal culdesacs of pleurisy on one side

The physical and neurologic examinations were negative except for marked loss of hearing in the left ear. At operation, November 10, a large arterial loop lying in the cisterna lateralis rested directly on the eighth nerve, about the middle of its intracranial curve. Because the hearing was practically entirely lost, the nerve was totally divided. The postoperative course was uneventful.

CASE 7.—M. B., a woman, aged 50, admitted Nov. 20 and discharged Dec. 1, 1936, complained of dizziness. The diagnosis was Ménière's disease due to an arterial contact with the eighth nerve (fig. 6).

Fig. 4.—Artery encircling and strangling the auditory nerve. There was complete deafness and total loss of vestibular response, but still there was enough function remaining in the nerve to cause the Ménière attacks.

The family and past histories were negative.

The patient was well until nine years before admission, when she noticed a roaring in the left ear. This had persisted, growing more intense with time. Two months after the onset of the roaring she noticed deafness in the left ear; this had also gradually progressed. Ten weeks before admission she noticed some unsteadiness of gait. There was some

dizziness induced by moving the head, but only on one occasion did objects rotate.

Physical and neurologic examinations were negative except for an almost total loss of hearing in the left ear and a slight coarse nystagmus to the left. At operation, November 21, subtotal section of the left auditory nerve was done. A large artery in the lateral cistern passed between the seventh and eighth nerves, definitely lifting the auditory nerve upward and definitely pressing the seventh nerve downward and forward. The postoperative course was uneventful.

CASE 8.—One of the most convincing observations concerning the causative lesions of Ménière's disease was an incidental finding on the auditory nerve during an operation for trigeminal neuralgia in which the cerebellar approach was used and in which the auditory nerve is always in full view. It was noted that an exceptionally large internal auditory artery lay on the outer surface of the auditory nerve; it ran longitudinally and covered over half of the surface that is ordinarily in full view (fig. 7). The comment was made at the time that this was a most striking lesion not to have induced Ménière's attacks. No history of dizzy attacks had been elicited before operation. On the following day when fully out of the effects of the anesthesia the patient was questioned about dizzy attacks in the past. She, a well nourished woman, a lawyer, aged 45, said that she had never had any. Five days later a typical severe Ménière's attack suddenly developed and lasted for two days. There was neither deafness nor tinnitus. A month after leaving the hospital and before returning to her home in the West, the patient called to see me. In the interim she had written her physician concerning our inquiries of earlier attacks of dizziness. Her physician reminded her that several years before she had sought relief for similar attacks of dizziness. These the patient had entirely forgotten, even when questioned about them, but recalled them after her physician's reminder.

#### COMMENTS ON LESIONS IN MÉNIÈRE'S DISEASE

**Tumors.**—Of the relationship of actual tumors in the cerebellopontile angle to the causation of Ménière's attacks, little need be said. As a matter of fact, in not a few case records of acoustic tumors one can find a story of perfectly characteristic Ménière's attacks. As far back as 1888, Sharkey<sup>3</sup> of England noted that the attacks in his case of proved acoustic tumor were

like those of Ménière's disease. In Murri's<sup>4</sup> case (1897) the attacks were also noted as being of this character. In an article on Ménière's disease, Frankl-Hochwart in 1898 called attention to several reports of tumors in this region with attacks of this character but wasn't convinced that the effect of the tumor on the eighth nerve was responsible for the attacks because injury to contiguous parts of the brain by the tumor was too widespread. He added "whether isolated disease of the auditory nerve can give rise to Ménière's attacks is questionable," for no known case has been reported.

It has always been my impression that dizzy attacks with acoustic tumors were very uncommon. I think this is the general impression. In his monograph on acoustic tumors Cushing<sup>5</sup> says that in only one instance was the history of dizzy attacks such as to suggest the diagnosis of Ménière's disease. However, a review of his case reports shows that in at least seven of the twenty-nine cases, i. e., nearly 25 per cent, there was a history of attacks of dizziness of this character, and in others the notation is entered that there was dizziness.

Although I have made no careful study of my series of acoustic tumors they have been abstracted up to 1930, and from a series of eighty-four cases up to that time sixty-four have a history of dizziness and dizzy attacks, fifteen are recorded as having had none, and in five dizziness is not mentioned. From the seventy-nine cases with an entry on this subject almost eighty per cent gave a history of dizziness. What proportion of these had real recurring sudden attacks of dizziness like those of Ménière's disease, I do not know. In many cases the dizziness is brought on by turning the head or by quick movements, and while the dizziness of the two types is doubtless fundamentally the same in origin, nevertheless the subjective expression is much more violent in the typical Ménière attacks.

Fig. 5.—Arterial loop falling on the outer surface of the auditory nerve.

The reason for the general erroneous belief that dizzy attacks are uncommon with acoustic tumors can be explained by the fact that dizziness is but a minor part in a group of severe signs and symptoms that are usually adequate enough to make the diagnosis. Then too the onset of dizzy attacks usually occurs among the earlier symptoms and is later lost when the function of the nerve is abolished by the growth of the tumor.

**Action of Cevitamic Acid in Pneumonia.**—After reviewing the literature on the antiallergic action of vitamin C and on the allergic mechanism involved in pneumonia, Hochwald describes the observations he made in the therapeutic use of vitamin C in cases of pneumonia. He reports twelve case histories but admits that the majority of the cases were so-called one-day pneumonias in which a spontaneous retrogression cannot be definitely excluded. He gained the impression that, if cevitamic acid is given early and in large doses, it exerts a therapeutic action on the pneumonia which becomes manifest in an improvement of the general condition (prostration, dyspnea and so on), quicker reduction of fever, earlier disappearance of the local symptoms and normalization of the leukocytic blood picture and, in some cases, of the urine. After the second day of the disease the cases are no longer suited for the cevitamic acid therapy. Moreover, the treatment may fail, even if it is administered before this term.

**Action of Magnesium on Automatic Ventricular Rhythm.**—Bloch and Pick reproduce and discuss electrocardiographic records of the modification by magnesium of the automatic stimulus formation. They demonstrate how the automatism that develops in the auricular fibrillation resulting from digitalis intoxication can be influenced. In summarizing their observations they point out that, in a patient with total ventricular arrhythmia resulting from auricular fibrillation, moderate doses of strophanthin and digitalis have a toxic effect and lead to the appearance of a subordinate pacemaker. The impulses originating in this pacemaker appear as series of regular automatic beats, only exceptionally as occasional automatisms, and take the place of the series of the superordinated fibrillation rhythm slightly bradycardized and regularized by digitalis. Pressure on the carotid of the left side, by inhibiting the conduction, favors the appearance of automatism, the series being noticeably prolonged. On the basis of reports in the literature the authors decided to treat this automatic heterotopism resulting from digitalis intoxication with magnesium sulfate. They found that the intravenous injection of a 20 per cent solution of magnesium sulfate checks the automatism and that there appears a slightly retarded and less regular transmission of fibrillation impulses. The retardation of the irregular fibrillation rhythm indicates an inhibition of the atrioventricular conduction by the magnesium sulfate. However, this effect of the magnesium sulfate is only temporary, its

duration being proportionate to the quantity injected (5 cc. acts five minutes, 15 cc. acts fifteen minutes). But even after the drastic action of magnesium sulfate has subsided, there still remains some effect in that automatism is no longer so pronounced.

Cancer Mortality in Vienna not Decreasing but Increasing. E. Fürth.—p. 96.

**Pathogenesis of Multiple Sclerosis.**—Dattner discusses the present status of the knowledge on the pathogenesis of multiple sclerosis, pointing out that it is not definitely known as yet. He cites various theories and describes his own studies on the problem. He admits that there is a bewildering mass of factors and observations, the organization of which is extremely difficult. First there is the fact that in the great majority of cases of multiple sclerosis there exist hematologic changes which can be demonstrated by means of the complement fixation reaction for tuberculosis but also by means of an alcoholic cerebrospinal extract, so that it can hardly be regarded as specific. Then it has been shown that, in the blood of patients with multiple sclerosis, there are lipolytic substances and higher diastase values, factors which indicate hepatic impairment. Further, it has been demonstrated that the blood coagulation of patients with multiple sclerosis is considerably prolonged and more unstable than in normal persons, which apparently likewise indicates hepatic impairment, perhaps a disturbance in the fat metabolism. The systematic investigation of the gastric secretion of patients with multiple sclerosis revealed anacidity or hypacidity in a considerable percentage of the cases but also cases with hyperacidity; that is, conditions similar to those which have been observed in pellagra and beriberi. Moreover, in a considerable number of patients hematologic changes were observed which were on the borderline of hyperchromic or hypochromic anemia. Finally, the symptomatology as well as the clinical course indicated many similarities with such avitaminoses as pellagra, beriberi and scurvy. The author shows that all these observations give rise to questions that cannot be answered on the basis of the present status of knowledge. At any rate, he considers the careful analysis of individual cases in the various directions as an aid to obtain a better insight into the pathogenesis of multiple sclerosis.

**Osteo-Articular Tuberculosis in Children.**—Stefko states that in tubular bones of children and adults one may observe isolated "primary" tuberculous foci that develop by the hematogenous route from tuberculous foci in the lungs or in the lymph nodes during the stage of primary infection. Such foci have been found by him in 80 per cent of the cases showing disease of bones and joints. According to their structure and origin, he distinguishes five forms of isolated foci: (1) intra-osseous perivascular, (2) lacunar (fibroid caseous), (3) fibro-caseous (Volkman and Kornev), (4) calcified and (5) capsular (bursal) foci. These foci appear chiefly in childhood (during the ages of 3 and 4 years) and may remain in a latent state for an indefinite time, accompanied by slight clinical syndromes or without manifestations. For the most part they cannot be revealed by x-ray investigation. When exacerbation of such foci takes place, one may observe (1) the appearance of new and smaller foci (osseous reinfections), (2) opening into the joint capsule or joint cavity and (3) development of proliferative processes in the form of intra-osseous growths of granu-

dizzy attacks. Such a large internal auditory artery attracted my attention in the first case of Ménière's disease that came to me for operation and before section of the nerve was known to be effective. The artery was so large that I thought it responsible for deafness and dizziness. The artery was clipped and the nerve left undisturbed. No appreciable benefit resulted; later the nerve was divided. It might appear on superficial consideration of this case that the absence of any beneficial effect from division of the artery would mean that the artery could not be responsible for the Ménière syndrome. In fact, it seemed so to me at the time. However, it is now known that a nerve once damaged still remains a potential source of subsequent attacks of Ménière's disease, just as a cerebral defect following the removal of a brain tumor or other lesion does not prevent subsequent attacks of epilepsy; they may indeed be less, but even this is not necessarily true. The epileptic attacks continue because the upper motor neuron is permanently damaged, and any imperfection of these tracts is for all time a potential source of convulsions.

However, it is only fair to add that the large ophthalmic artery passes through the optic foramen alongside the optic nerve and is not thought to be the cause of any trouble. But perhaps it too may be responsible for some of the losses of vision for which causes are unknown.

The five large arteries reported here do not represent the positive results from the entire series but only from the past year's experience, excepting the first case, in which operation was done two years ago and which in itself clinched the pathologic relationship. The actual percentage of large compressing arteries in this line is therefore approximately 10 per cent. But in addition there are many such vascular trunks that are less obtrusive but are only of smaller size. It is, of course, always difficult to tell with any degree of certainty where the large effective vessels end and the smaller noneffective ones begin. For this reason I have confined the pathologic presentation to the lesions that would appear to be unequivocal. If those of somewhat lesser size are added, the percentage of effective vascular lesions would probably be in the neighborhood of from 30 to 40. Even this leaves approximately two thirds in which no demonstrable cause can be seen at operation and far more than there is reason to believe could be filled in from the unexposed portions of the auditory nerve. Moreover, it is known that probably from 8 to 10 per cent of the total number of cases of Ménière's disease are bilateral, and these could not be explained on bilateral lesions along the auditory nerve. The only conceivable cause of bilateral cases must be some intrinsic lesion of the auditory vestibular pathways in the brain stem. If an intrinsic lesion causes the bilateral cases, there is doubtless a similar explanation for many of the unilateral cases. It is not my purpose, therefore, to suggest that the gross lesions here described account for more than a fraction—perhaps one third—of the cases. Since these arteries have always been in contact with the nerve, the reader may wonder why the attacks of dizziness, deafness or tinnitus come so late in life. It is, I think, because the arteries become more rigid with age. In case 4 the arterial noose had produced its effect since birth. The thought has also arisen that possibly venous contacts, such as one sees along the sensory root of the trigeminal nerve (branches of the large petrosal vein) may

also be responsible for Ménière's disease. But I have never seen a vein along the intracranial course of the auditory nerve.

McKenzie<sup>10</sup> has also been independently impressed with the significance of the arterial loops along the auditory nerve. During the discussion of my paper on bilateral Ménière's disease at a meeting of the American Neurological Society in 1935, when case 4 with the strangled nerve from an arterial noose was presented, McKenzie noted that in six of his last fourteen operations an abnormally situated anterior inferior cerebellar artery has "passed through or was lying upon the nerve."

#### OTHER LESIONS REPORTED IN THE LITERATURE ON MÉNIÈRE'S DISEASE

Wittmaack<sup>11</sup> found concretions in the ductus cochlearis of two patients who had had Ménière's disease. In one of these cases there was also a minute neuroma in the cochlea. It was his belief that the concretions had wrought "pressure" changes in the vestibular canals, much as closure of the canals of Schlemm results in glaucoma. Just<sup>12</sup> includes a reference (which I have been unable to obtain) by Zange, who found a small hematoma in the brain stem near one of the nuclei of the auditory nerve; the vestibular canals and cochlea showed no gross abnormality.

#### PATHOLOGY

A few years ago I brought certain evidence to prove that the attacks of Ménière's disease were analogous to those of trigeminal neuralgia and epilepsy and that only a lesion in the higher sensory or motor neuron could induce any of these attacks. It is therefore my belief that only lesions of the sensory root of the auditory nerve (its vestibular division) can cause Ménière's disease, and consequently lesions in the semicircular canals such as concretions would not be a cause. However, although I do not believe that concretions in the cochlear aqueduct can cause recurring attacks of dizziness and loss of hearing, I am not able to make a categorical denial that they may do so. The effects of irritative or occlusive concretions in this channel are not yet known. It would be difficult, however, to understand how an occlusion in the ductus cochlearis could affect the semicircular canals, which, although connected through the ductus endolymphaticus, should nevertheless be entirely independent of any secondary effect from an obstruction. Of the theory of Portmann<sup>13</sup> and Aboulker,<sup>14</sup> who conceive that pressure effects are transferred from the cisterna lateralis through the ductus endolymphaticus, one can be quite positive. That pressure in the lateral cistern does not in any way affect the semicircular canals or organ of Corti is easily shown by the entire absence of effect from the great numbers of brain tumors that are known always to produce a rise of pressure in the lateral cistern, and never is there any pathologic effect on hearing or vestibular function. Such a conception is purely a fanciful theory without any anatomic background whatever. Nor has there been in a single operative exposure of the lateral

## **PATHOLOGIC CHANGES IN MÉNIÈRE'S DISEASE**

WALTER E. DANDY, M.D.  
BALTIMORE

In previous reports I have shown that Ménière's disease and pseudo-Ménière's disease could be cured by section of the auditory nerve or equally well of the vestibular branch alone. The series of operations has now reached 170 in 160 patients, ten being bilateral. There has been no death and, except for four early facial palsies, no after-effects in the unilateral cases. There are few diseases so easily diagnosed and so perfectly curable.

Like trigeminal neuralgia the cure of Ménière's disease has antedated the disclosure of its underlying cause. Since the disturbances (chiefly recurring attacks of dizziness in which objects rotate) do not in themselves produce death, pathologic material is exceedingly scarce. Ménière's original description of "a serosanguineous exudate<sup>1</sup> in the semicircular canals" was not from a case of Ménière's disease as was supposed but from a case of acute purulent labyrinthitis—an acute infectious disease having no clinical resemblance whatever to Ménière's disease. Ménière's efforts to associate the pathologic picture with Ménière's disease shows that even in his own mind the syndrome was none too sharply defined. The absence of necropsy material throws the burden of pathologic disclosures on conditions found at operation. From this source a series of gross lesions is offered as the unequivocal cause of Ménière's disease. In another group of cases, representing perhaps 30 per cent of the whole series, it is believed that the gross lesion is also demonstrable; but for the present at least these changes are merely mentioned but are not presented as being unequivocally the cause. However, it is only with the small series of absolutely positive causes that this paper is concerned.

CASE 1 (first reported in my first paper<sup>2</sup> on Ménière's disease.) *History*.—A. L., a woman, aged 63, admitted Nov. 22 and died Dec. 2, 1927, was rather feeble and was seen in consultation with Dr. Leslie N. Gay of Baltimore. Her first symptoms were gradually progressive deafness and tinnitus of the left ear (the right ear was almost deaf from an old infection during childhood). One year later, suddenly and without warning, she was seized with a terrific attack of dizziness during which there were nausea and repeated vomiting. The room seemed to jump around, the bed to tilt up and the walls to move in every direction. There was no definite

revolving sensation. The attack lasted about thirty minutes. Brief spells of much the same character occurred almost daily. Any quick movement would induce dizziness. The deafness varied greatly from time to time. Tinnitus was constant in the left ear. Her eyesight became so poor that she could not read. She never had headaches. The systolic blood pressure varied greatly during Dr. Gay's observations over a period of several months. Usually it ran from 160 to 190 but had been as low as 110. Her hands and feet were swollen at times, even when in bed; at other times the swelling was absent.

One month before operation her symptoms became much more severe. Roaring was nearly always present throughout the head and was often referred to both ears. The hearing became much worse. Her gait was unsteady and uncertain. The left corneal reflex was diminished.

Caloric response on the affected side was normal. Irrigations started mild attacks of dizziness and nausea.

The audiometer test showed 63.5 per cent loss of hearing in the right ear (old deafness) and 65 per cent loss in the left (affected side).

*Operation*.—November 22, the left auditory nerve was totally divided. An aneurysm was found under the eighth nerve. It was traced downward and was continuous with the vertebral artery. Two days after operation, the old noises returned. One week later it was noted that she could not lie on the left side (the nerve was cut on this side) for any length of time because nausea and vomiting would start, but dizziness had not been present since operation. The patient's condition became slowly worse and the noises became unbearable. She was unable to stand. Three weeks later the left vertebral artery was tied in the neck. At the same operation the right vertebral artery was exposed and momentarily compressed between the blades of the forceps; death resulted apparently simultaneously and instantly—the quickest death I have ever seen. Immediate release of the forceps was unavailing. The aneurysm is shown in figure 1.

CASE 2.—*History*.—K. B. D., a woman, aged 47, admitted Dec. 3 and discharged Dec. 24, 1935, complained of blurred vision, staggering gait and dizzy attacks. The diagnosis was acoustic tumor on the right. The family and past histories were negative.

Three years before admission to the hospital the patient was suddenly seized with a feeling of fullness in the right ear; this sensation soon disappeared and has never recurred. Severe headaches and blurring of vision began one year before admission. The headaches came nearly every day and lasted for several hours. Shortly afterward attacks of vertigo developed; with these there was rotation of objects. A roaring noise persisted in the left ear; it was not influenced by the vertigo. Nine months before admission she fell unconscious and remained so for several hours. On awakening, the left side of the face was numb and the face distorted. Staggering gait next developed. All the symptoms have been gradually progressive.

During the dizzy attacks the room and everything in it would spin around. She was forced to lie down immediately.

*Examination*.—Except for numbness of the face on the contralateral side, all signs indicated a tumor in the right cerebellopontile angle. The Romberg sign was positive and she fell in every direction. Hearing was totally lost in the right ear and was normal in the left. There was spontaneous nystagmus to the left. Irrigation of the ears with cold water produced no effect on either side.

1. In many textbooks the statement is erroneously made that an actual hemorrhage was present. His pathologic description in 1861 of course antedated the knowledge that diseases were caused by bacteria and, therefore, it was not known that bloody exudate was merely the product of an infection.

2. Dandy, W. E.: Ménière's Disease: Its Diagnosis and a Method of Treatment, Arch. Surg. 16: 1127 (June) 1928.

175

anaerobic and grows very readily on the ordinary abundant growth with turbidity, slimy sediment and pellicle formation. On agar plates the colonies appear within from twenty-four to forty-eight hours as round, raised, slimy, gray colonies, which string out when drawn up with a wire loop.

A great advance was made in the study of this organism with its biologic classification by Julianelle<sup>9</sup> in 1926. He classifies the strains by the immunologic reactions of agglutination; precipitin reaction and passive protection against infection into three specific types designated as A, B and C. These three types comprise the great majority of strains noted clinically, the remainder being included in a heterogeneous group designated as X. Miss Georgia Cooper<sup>10</sup> of the Department of Health of New York City succeeded in further isolating two distinct types from this last group, which she designated as D and E, and it appears likely that still more types will be isolated in the future. Biologically this organism has many points in common with the pneumococcus. The distinctions in type were shown by Julianelle to depend on the presence of a

Age incidence of Friedländer's pneumonia.

specific carbohydrate in the capsular material, slightly different for each of the types, which constitutes the soluble specific substance excreted in the urine in infections with this organism. As with other organisms, both S (smooth) and R (rough) strains are found. The S strains produce capsules, are type specific and are highly virulent. Immunization with S organisms induces the formation of antibodies which agglutinate specifically and protect mice against infection by organisms of the same type. The R strains produce no capsule and no soluble specific substance and are not pathogenic. They are serologically undifferentiated from one another and react only with the species antibodies. Decapsulation of the S cells by heat and acid chemically converts a type-reacting S organism into a species-reacting R organism.

In 1921 Toenniessen<sup>11</sup> noted that Friedländer's bacillus when grown in symbiosis with *Bacillus vulgatus* loses its capsule as the result of the enzyme action of the latter organism, but he apparently had no interest in applying this discovery to the problems of experimental or clinical immunity. It is of interest, however, to note that following the work of Toenniessen, Dubos and his co-workers<sup>12</sup> in 1931 isolated another enzyme that experimentally is capable of protecting mice and

monkeys against infection with type III pneumococcus, an organism whose capsule has a close chemical resemblance to that of Friedländer's bacillus.<sup>13</sup>

#### EPIDEMIOLOGY

The Friedländer bacillus is a fairly common cause of infection of the biliary and the genito-urinary tract and has also been found as the etiologic factor in pericarditis, meningitis and septicemia. It is found as a normal inhabitant of the upper respiratory tract in a small percentage of normal persons, the incidence varying, according to different investigators, from less than 1 per cent<sup>10</sup> to more than 4 per cent.<sup>14</sup> Hence its pathogenicity is questioned, it being considered by some as merely a secondary invader. This objection, however, does not appear to be valid, as the pneumococcus, streptococcus and other organisms are found as saprophytes in the upper respiratory tract but may on occasion cause pulmonary disease.

The relationship between carriers and cases of Friedländer's pneumonia has not received the study that a similar relationship in the case of the pneumococcus has had. It is appropriate to record in this connection the instance of a resident physician<sup>15</sup> who, following contact with a case of Friedländer type A pneumonia, developed a severe pharyngitis from which this organism was isolated in pure culture and made a complete recovery without contracting pulmonary disease. Ferguson and Tower<sup>16</sup> report the occurrence of Friedländer's pneumonia in twin infants, one contracting the disease five days after the other. As in pneumococcal pneumonia, there is no conclusive information regarding the incubation period except that it is probably short. Webster<sup>17</sup> observed in a spontaneous epidemic of Friedländer's pneumonia among mice that the incubation period was forty-eight hours. He further helped to clarify the rôle of carriers experimentally by noting that, when a few carriers were placed in contact with healthy mice, some of these mice died in five days, while from 50 to 70 per cent died within two weeks of the disease.

#### INCIDENCE

The incidence of Friedländer's pneumonia is variously stated by different authors as from 0.5 per cent<sup>15</sup> to more than 5 per cent<sup>10</sup> of all cases of pneumonia. In this series, among 5,000 cases of pneumonia reviewed, thirty-two were found to be due to the Friedländer bacillus, an incidence of approximately 0.6 per cent. This estimate is unquestionably low for reasons already stated. It is perhaps significant that during the seasons 1933-1934 and 1934-1935 when all the pneumonia cases in the Fourth Medical Division were carefully studied clinically and bacteriologically by me with this in mind, twelve cases were found among approximately 300 cases of pneumonia of all types, an incidence of 4 per cent.

Unlike pneumococcal pneumonia, this disease seems to occur almost exclusively in late middle age. The

quency and severity of these attacks she had been unable to attend school; she had been tutored at home and was exceedingly bright. Her mother said she had been clumsy with her hands and that her gait had been awkward between the attacks.

**Examination.**—The physical examination was entirely negative. The Romberg sign was questionably positive, the gait practically normal. There was slight unsteadiness, probably because the patient had been in bed so long. The right ear was stone deaf; the caloric test gave no response in this ear. Hearing in the left ear was quite normal and the caloric response was normal. The remaining neurologic examination was negative.

Although I have never seen Ménière's attacks at such an early age, there could scarcely be a doubt that the attacks were of this type. It is interesting that the very early seizures were not associated with the dizziness, which came somewhat later. Since she was totally deaf and had no caloric response in the right ear, I could not believe that this ear could have any bearing on the attacks; and since the hearing always diminished in the left ear (the good ear) before the attacks, the left ear was thought to be responsible for her seizures.

**Operation and Result.**—Accordingly, November 6 the vestibular branch of the left auditory nerve was divided, the cochlear branch being left intact. There was one definite anatomic abnormality, but its character was not such that one could assume any connection with her attacks. The outer wall of the lateral cistern was some distance external to the auditory nerve, whereas normally this arachnoid membrane runs along and is attached to it. When the angle was exposed, one could see the white eighth nerve in the depths of the cisterna lateralis. This is merely mentioned as one of a series of congenital abnormalities.

During the following three days the patient was quite miserable and felt nauseated, but there were no definite complaints. On the fourth day she was quite ill and tinnitus appeared in both ears; the hearing began to diminish and her mother predicted that an attack was coming. Her skin was so sensitive that even the weight of the bed covers caused her distress. This had been a positive sign that an attack was coming. In the afternoon she awoke suddenly, following a dream in which she was falling; she screamed that an attack of vertigo was coming. Her extremities were rigid and she stared straight ahead. This attack lasted a few moments but was quickly followed by six others of similar character; there was neither vomiting nor headache; objects whirled about the room. There could be no doubt that the patient was having her original attacks and that section of the nerve had failed to produce any benefit. Two possibilities occurred as explanations of the failure: (1) perhaps, in our eagerness to save the hearing in the only functioning ear, the vestibular fibers had not been totally divided; (2) possibly the seemingly dead right auditory nerve might yet have a bearing on these attacks. It was finally decided to divide the seemingly functionless right auditory nerve. This was done November 11. The arachnoid was attached to the eighth nerve, as it normally is, but in contrast to the condition described on the other side. A striking observation was an arterial loop totally encircling and tightly strangling the eighth nerve as if it were in a noose. It surrounded the nerve just mesial to the acoustic foramen. The artery was fairly large and the nerve was so short that its division was somewhat difficult. Two little branches of the artery coursed toward the acoustic foramen and were thrombosed and divided. The arterial loop was then gently pushed mesially, giving just enough free nerve to permit its section near the acoustic foramen. There was no doubt in our minds that this arterial loop was causing the deafness and, as the subsequent course of events appeared to indicate, it was doubtless the cause of her attacks. Although she was fairly prostrated by the attacks antedating the operation, and doubtless, too, by the mental reaction of the unsuccessful operative procedure on the left side, she rapidly improved mentally and physically and left the hospital eleven days later.

It is now two years since the operation and at no time has there been the slightest suggestion of her earlier attacks; there has been no dizziness on turning the head and no diplopia. The hearing on the left side remains normal. For several months there was difficulty in walking, particularly with the eyes shut; even with the eyes open she at first staggered markedly, but there has been steady improvement in this respect until now she walks quite well. She has also had the customary blurring of objects when walking or moving, but this too has greatly improved.

**CASE 5.—History.**—H. K., a girl, aged 15 years, admitted Sept. 29 and discharged Oct. 10, 1936, complained of dizzy attacks. The diagnosis was Ménière's disease. The family and past histories were negative.

For the past four years the patient had noticed some deafness in the left ear. A year before admission, dizzy attacks began; these lasted about twenty minutes and came on without warning and without apparent cause. On several occasions she had fallen, usually to the left side. There had been no nausea or vomiting. There had been some tinnitus in the left ear.

**Examination.**—Except for almost complete loss of hearing and a very mild response to the caloric test in the left ear, there were no neurologic changes.

Fig. 3.—Cyst with intracystic papilloma in the left cerebellopontile angle. This caused Ménière's attacks by compression of the eighth nerve.

**Operation and Result.**—September 30 the left vestibular nerve was totally divided. There was a small artery encircling the nerve just at the point where it passes under and is attached to the cerebellum. The artery was closely bound to the outer surface of the nerve over its entire width. The patient has been well to date (Dec. 1, 1936).

**CASE 6.—M. L.,** a woman, aged 46, admitted Nov. 9 and discharged Nov. 21, 1936, complained of attacks of dizziness. The diagnosis was Ménière's disease caused by a vascular loop lying on the auditory nerve (fig. 5). The family and past histories were negative.

The patient had perfectly typical attacks of dizziness for the past five years; each attack would last from two to five hours. They would come on an average of once a month until the past six months; since then they had occurred almost weekly. There had been progressive deafness in the left ear since the onset of her attacks. There had also been tinnitus in this ear. In some attacks there had been nausea and vomiting. After her operation, and without knowing what had been done, her cousin volunteered that she had been deaf in the left ear since childhood. She was subsequently asked about this and denied it and gave evidence of the fact that her hearing had been very carefully tested before she was given a position with the telephone company.

DISTRIBUTION OF PULMONARY LESION

The anatomic character of the pulmonary involvement appeared from physical examination and from fluoroscopy to be lobar in twenty-seven cases (84 per cent) and patchy or lobular in four (16 per cent). Moreover it was not uncommon for a lobar consolidation of one lobe to be followed by a bronchopneumonic involvement of another. It is worthy of mention that only in approximately half the cases in which there was lobar involvement were the physical signs those of frank consolidation. In the remainder there was merely dulness and suppressed breath and voice sounds with a few râles, bronchial breathing being absent even when the consolidation was well advanced, as demonstrated by fluoroscopy or necropsy. This phenomenon may be due to the filling of the smaller bronchi with mucinous exudate, thus preventing passage of air through them. As seen from table 1, the commonest lobes to be involved were the right lower lobe and the right upper lobe, there being four cases of each. Involvement of more than one lobe was very frequent, occurring in eighteen cases (65.2 per cent). Upper lobe involvement was more common than is usually seen in other forms of pneumonia, occurring in six cases (18.7 per cent), and in conjunction with involvement of other lobes in thirteen other cases (40.6 per cent), a total of nineteen cases (59.3 per cent).

THE SPUTUM

One of the most distinctive features of this disease is the character of the sputum. This is usually a thick mixture of blood and mucus, brick red, and so homogeneous as to appear as if the blood and the mucus had been whipped together into a uniform emulsion. In appearance it resembles chocolate pudding, though of a redder hue. This character of sputum was noted at some stage of the disease in twenty-five of the cases (78 per cent). The quantity varies, sometimes being scant, at other times copious. If pulmonary edema supervenes it may become thin, pink and frothy, and if

abscess formation occurs it may occasionally, though not usually, become foul. A direct smear of the sputum stained by Gram's method will usually show a predominance of large gram-negative bacilli with a refractive zone around them representing the capsule. If the sputum is injected into the peritoneal cavity of a mouse, as is done in routine sputum typing, it is digested much more rapidly than the usual pneumonic sputum, probably owing to the fact that it is already emulsified. Within two to three hours a drop of peritoneal exudate, obtained through a capillary pipet by the method of Sabin,<sup>23</sup> shows a pure growth of Friedländer's bacillus.

The organism causes a septicemia in the mouse, the animal usually dying in from eight to twenty-four hours; the bacillus can then be recovered in the heart's blood. A simpler method perhaps is to streak a drop of sputum on an agar plate and incubate it for from twenty-four to forty-eight hours. The characteristic slimy gray colonies will then be noted on the plate. It seems important to differentiate the gross character of the sputum from that seen in other pulmonary diseases because, once this fact is properly appreciated, it becomes possible to suspect the diagnosis from this

feature alone. The sputum may be confused chiefly with that from a pneumococcic pneumonia or from a tuberculous patient with hemoptysis. The ordinary "pneumonic" sputum, however, is the color of prune juice and is more viscid and ropy, resembling taffy rather than an emulsion. That of hemoptysis is either pure blood or the bloody streaking of a mucopurulent sputum. It is imperative to examine a smear stained by Gram's method, which will usually confirm or disprove the suspicion of Friedländer's pneumonia before the sputum typing is completed. The latter procedure should not be omitted, however, as it constitutes more certain proof.

In ten of the cases an attempt was made to differentiate further the type of Friedländer's bacillus obtained from the sputum by agglutination tests and by the Neufeld reaction, and in each case a type A organism was found. This predominance of the type A organism in pneumonia is in agreement with the observations of Julianelle<sup>9</sup> and Cooper,<sup>10</sup> who estimate its incidence as 75 per cent and 95 per cent respectively. In this series it was found to the exclusion of all other types.

LUNG CULTURE

Lung puncture with the aspiration and culture of lung juice was resorted to as a diagnostic measure in ten cases. In each the Friedländer bacillus was found, and in eight of the ten the organism was typed and found to belong to group A. Moreover, in six additional cases lung culture at autopsy disclosed the Friedländer bacillus. These cases are cited though comprising only half of the group because of the uniform discovery of the infecting organism in pure culture in the lung juice or the lung tissue. The value of this finding is further enhanced by the fact that in no instance in which the attempt was made was there failure to find the Friedländer bacillus, nor was it associated in any case with other organisms.

BACTEREMIA

The incidence of bacteremia in this series is summarized in table 2. Blood cultures were taken in twenty-seven cases, nineteen (73 per cent) showing positive cultures, all of which ended fatally. In six cases in which the organism was typed it was found

23. Sabin, A. B.: The Microscopic Agglutination Test in Pneumonia, J. Infect. Dis. 46: 469 (June) 1930.

Doubtless if this phase of the illness should be investigated with greater care, the actual number of cases with clear-cut Ménière's attacks would be much greater.

From my entire series of cases of Ménière's disease an actual tumor has never been disclosed unless, in addition to the dizzy attacks, there were other signs and symptoms indicating the tumor's existence. So striking has been the absence of tumors in such a large

Fig. 6.—Large artery passing between the seventh and eighth nerves and causing elevation of the latter.

group of cases that I have acquired a feeling of confidence in excluding tumors, even though the objective changes of Ménière's disease and early acoustic tumors are precisely alike. And yet if the third patient in this series (case 3) had been seen at any time during the first three and one-half years of his illness, or the second patient (case 2) during the first two years, it is very doubtful whether the tumor would have been suspected.

That Frankl-Hochwart's<sup>7</sup> objection that pressure of the tumor on other parts of the nervous system and not involvement of the auditory nerve may be responsible for the seizures can now be answered in the negative, for section of the eighth nerve always permanently abolishes the attacks.

That tiny tumors may exist in those parts of the auditory nerve which are undisclosed at operation is, of course, always a possibility. Recently Hardy and Crowe<sup>8</sup> reported a series of six cases of this type, discovered at necropsy during a routine study of serial sections of 250 temporal bones. Because of their minute size all had been missed in the gross inspections at autopsy. In addition there had been ten angiomatous masses in the vestibular division of the nerve—a total therefore of sixteen small tumors; i. e., approximately 6 per cent of a series of cases taken at random and not chosen because of symptoms referable to the auditory tract. Of the six cases in which there were tumors (excluding the angiomatous network in the nerves) it is noted in three that there was no history of vertigo, and in the remaining three no history of the patient was obtained. As all these patients died of other causes,

the past histories may well have missed<sup>9</sup> dizzy attacks had they occurred. The significance of this series of cases lies in the fact that so many gross lesions may exist in the auditory nerve and still escape detection.

**Arterial Causes.**—Evidence that arterial contacts with the bare sensory root of the trigeminal nerve in the posterior cranial fossa were responsible for most cases of trigeminal neuralgia was presented by me in 1933. Subsequent experiences since that time have strongly fortified that impression. The thought that similar lesions might account for Ménière's disease was a natural outgrowth of these disclosures. It has been much more difficult to reach this conclusion because in so many cases there is no obvious gross vascular anomaly, although it must be realized that only approximately half of the total length of the auditory nerve is seen at operation. The eight cases here presented are, however, so outspoken that argument would appear to be unnecessary. Not the least impressive is case 8, in which the dizzy spells were predicted from just such a vascular anomaly as was seen on and largely obscuring the outer surface of the eighth nerve during an operation for trigeminal neuralgia. It is only fair to add, however, that an identical vascular anomaly has since been seen in another patient, and no history of attacks of dizziness could be subsequently elicited. The absence of disturbances from such a lesion is probably less significant than their presence, just as one may have no symptoms from gallstones for a long time at least. But, given the symptoms and the gallstones, the causal relationship is clear.

Only five other vascular lesions on the auditory nerve have been chosen, two in which arterial loops have seemingly strangled the auditory nerves, and three in which a large looping artery, free in the cisterna lateralis, has lain on the nerve. The vascular variations in the region of the auditory nerve are such that one has difficulty in establishing the normal. Not the least surprising is that an internal auditory artery is so

Fig. 7.—Large internal auditory artery covering the auditory nerve. This was found during an operation for trigeminal neuralgia. It was later learned that the patient had had Ménière attacks.

infrequently found and when found is of such tiny caliber. Small arteries under, over, in front of, behind or actually in the nerve are not such as to excite the impression of any causal relationship, but when the artery is more than half the size of the nerve and is directly on the nerve it is difficult to believe that the artery is not affecting the hearing and producing the

9. In the only case from this hospital there was not a word about the presence or absence of dizziness; the note concerning the absence of this symptom was obtained from his wife in response to a letter from Dr. Crowe.

tion,<sup>25</sup> but to my knowledge this is the first instance of such a superinfection of the blood stream in Friedländer's pneumonia. To complete the list of complications, delirium occurred in eleven cases and tympanites in three.

In addition, in a few cases, associated conditions were present which did not appear in any way related to the pneumonia. There was one instance of each of the following: duodenal ulcer, cholelithiasis, hypertrophied prostate and nephrolithiasis with cystic kidneys and two instances of cirrhosis of the liver. Several other patients were admitted to the hospital for some other condition and developed pneumonia as a complication: one man admitted for food poisoning developed pneumonia five days after admission and died. One patient developed this fatal pneumonia following a Caldwell-Luc operation for a purulent antrum, and one as a complication of a severe arsenical hepatitis (case 10). Another patient was admitted for chronic nephritis and asthma and later succumbed to Friedländer's pneumonia.

#### TREATMENT

The treatment did not differ greatly from that employed as a routine in pneumonia. It was mainly supportive and symptomatic, consisting of bed rest,

TABLE 3.—Results in Five Cases Treated with Specific Serum

	Day of Disease Started	Day of Serum Given	Total Amount of Serum U./Cc., Total Units	Blood Culture Before Serum	Blood Culture After Serum	Agglutinins Before Serum	Agglutinins After Serum	Day of Death

Case 2	5th	110	88,000	30 colonies	30 colonies	Absent	Absent	6th
Case 3	4th	400	320,000	Sterile	5 colonies	Absent	Present	6th
Case 4	5th	230	184,000	Growth in broth	110 colonies	Absent	Present	8th
Case 5	2d	70	56,000	Sterile	Not taken	Not done	Not done	3d

liquid diet, high fluid intake and enemas as required. When indicated, circulatory stimulants, intravenous dextrose and whisky were given. Oxygen, either in a tent or by nasal catheter, was employed to combat cyanosis and dyspnea. Symptoms such as distention or delirium were treated in the usual manner as they arose. Pleural effusions were sufficient in quantity only in one instance to require thoracentesis. In the two cases complicated by empyema a thoracotomy was done in one two days before death, and in the other the empyema was not diagnosed during life. When meningitis occurred it was treated by daily spinal punctures and sedatives.

Specific horse serum<sup>26</sup> for type A Friedländer's pneumonia was employed in five cases. The results are summarized in table 3. All five cases ended fatally, three of them within twenty-four hours after treatment was started. In only two cases was an adequate quantity of serum administered. While it obviously did not alter the ultimate outcome, it is of interest to

determine whether there was any effect on the immunologic progress of the disease. From the table it would seem that there was no inhibiting effect on the bacteremia. In two instances in which the agglutinins for the infecting organism were at first absent in the blood stream, they appeared after the administration of serum; in two instances they did not. The appearance of the agglutinins in the former cases cannot with certainty be accredited to the serum therapy, because another patient in this series who received no serum developed agglutinins spontaneously on the fifth day. The lack of success with the serum in these cases is not a fair criterion of its value. It would be of distinct advantage to observe its effect in a larger group, particularly in early cases with larger amounts of serum. The failure of the serum may be due in part, as in the case of the type III pneumococcus, to the peculiarly thick, slimy capsule of the organism. In that event further experimental investigation along the lines suggested by the work of Toennissen<sup>11</sup> and Dubos and Avery<sup>12</sup> might be fruitful.

#### PATHOLOGY

The scope of this article does not permit any detailed discussion of the pathologic changes. Eighteen of the thirty-one fatal cases came to autopsy. Suffice it to say that in general the involved lobe or lobes appear voluminous, heavy and consolidated, the degree of consolidation varying with the stage of the disease. The color of the consolidated lung varies from chocolate brown to gray. The cut surface appears smooth and mottled but not granular, as in pneumonia due to the pneumococcus, and is covered by a characteristic viscid, abundant, mucinous exudate which sticks to the knife. The lung as a rule is softer and very frequently has areas of necrosis with abscess formation. The latter condition was well marked in six of the cases. Moreover, when it was not noted grossly it was common to find necrosis and destruction of the alveolar walls microscopically. The exudate filling the alveolae varies in character, consisting in most cases of a mixture of polymorphonuclear cells and large mononuclear cells with a few red blood cells. The percentage of monocytes varies; in some cases they are the predominant cell in the exudate. Cultures of the lung, if the autopsy is done shortly after death, yield the Friedländer bacillus, and on microscopic section the organisms can be seen in large numbers as gram-negative encapsulated rods lying in the cells or free in the alveoli.

#### DISCUSSION OF LITERATURE

Following the reports of Friedländer,<sup>1</sup> Fraenkel<sup>2</sup> and Weichselbaum,<sup>3</sup> scattered cases of this condition were recorded. Among the earliest clinical reports was that of Etienne,<sup>14</sup> who observed two fatal cases. He asserted that this form of pneumonia was usually patchy or pseudolobular and emphasized the gravity of the prognosis. Beco<sup>27</sup> in 1899 recorded the first case of bacteremia occurring in a Friedländer bacillus pneumonia. Further reports appeared, among them those of Thirollox,<sup>28</sup> Smith,<sup>29</sup> Howard<sup>19</sup> and Kokawa,<sup>30</sup> which in the main presented the disease as an acute fulminating pneumonia occurring in adults, generally bronchopneumonic in distribution, with alcoholism and

cisternae in this series any abnormal finding and certainly there has been nothing suggestive of a localized meningitis, which is almost an impossible conception.

## SUMMARY

1. Two tumors and one aneurysm of the basilar artery are known to have caused Ménière's disease.

2. A series of five large arterial loops (from the anterior inferior cerebellar artery) in the lateral cisternae are, I believe, equally positive lesions in the production of Ménière's disease. They act by strangling or compressing the auditory nerve.

3. From the cases which came to operation during the past year about 10 per cent showed contacts from large arteries. In addition there are many vessels of smaller size that doubtless produce the same effect.

Johns Hopkins Hospital.

## PRIMARY FRIEDLÄNDER PNEUMONIA

## REPORT OF THIRTY-TWO CASES

SAUL SOLOMON, M.D.

NEW YORK

Carl Friedländer<sup>1</sup> in 1882 described an organism which he found at necropsy in several cases of croupous pneumonia. He expressed the view that it was the chief etiologic agent of lobar pneumonia, thus precipitating a controversy which was not settled for many years. It is now generally agreed that Friedländer's observations were correct but that his deductions were too sweeping and based on insufficient data. For, soon after this, Talamon,<sup>2</sup> Fraenkel<sup>3</sup> and Sternberg<sup>4</sup> showed conclusively that the common cause of lobar pneumonia was *Diplococcus lanceolatus* or pneumococcus. It was their view that the organism described by Friedländer was not a true cause of pneumonia at all but merely a secondary invader. This swing of opinion regarding the pathogenicity of Friedländer's bacillus appears to have been as extreme and erroneous as Friedländer's original conclusions. Weichselbaum<sup>5</sup> approximated more closely to the truth as the result of a study of a larger number of cases. He confirmed the rôle of the pneumococcus as the usual cause of lobar pneumonia but added that in a small though definite percentage of cases the Friedländer bacillus was the etiologic agent. Reports from numerous sources have accumulated since that time to support this view, and at present the evidence in favor of it appears convincing. Nevertheless considerable doubt has been expressed by some investigators as to the actual significance of this organism in pneumonia.

The purpose of this report is to present additional evidence concerning the relationship between the Friedländer bacillus and certain cases of pneumonia and to determine whether there exists a characteristic clinical entity which distinguishes them from the usual cases of

pneumonia or other pulmonary conditions. It may perhaps also serve to call the attention of clinicians to a disease which, though not rare, has received scant attention in the literature. Thirty-two cases are presented which, aside from the report of Zander,<sup>6</sup> is the largest series thus far reported. That there is need for such a study is further evidenced by a review of the incomplete and frequently misleading information in the textbooks that deal with the subject.

## MATERIAL OF STUDY

Approximately half of this series of cases were observed and studied by me mainly during the course of an investigation into the therapeutic value of certain antipneumococcus serums.<sup>7</sup> With the permission of the directors of the First, Second, Third and Fourth Medical Divisions of Bellevue Hospital, to whom I am indebted, a search was made of the pneumonia records<sup>8</sup> as far back as 1920, yielding a number which brought the total up to forty-two. Of these, thirty-two were acute and ten were chronic cases of Friedländer's bacillus infection of the lung. The latter are not included in the present report, since they form a distinct group, having a totally different clinical course, and it is hoped that they will be reported separately at a later date. A large number of other cases were excluded from this series in which Friedländer's bacillus was found in association with other organisms such as the pneumococcus, streptococcus or tubercle bacillus, as it is intended here to present only cases in which there is sufficient clinical and bacteriologic evidence to warrant the conclusion that they are true cases of primary pneumonia caused by Friedländer's bacillus alone. Owing to the fact that pneumonia records in the past have been classified and filed anatomically and not etiologically, the task of discovering instances of this special type has been exceptionally difficult. There seems little doubt that this group by no means represents all the cases occurring in Bellevue Hospital in the past fifteen years both for the foregoing reason and also because it is probable that a large number escaped clinical recognition. This form of pneumonia is much commoner than is generally realized, and if certain distinguishing features are kept in mind the diagnosis can be readily suspected and quickly confirmed. This is of importance not only because the prognosis is much more serious than in pneumonia due to other organisms but also because it makes unnecessary the use of antipneumococcus serum, and because a widespread early recognition would greatly enhance the efforts to find an effective treatment.

## BACTERIOLOGY

The causal organism is the Friedländer bacillus, which is sometimes designated as the pneumobacillus or bacillus mucosus-capsulatus. It is a gram-negative rod, varying in length from 0.5 to 5 microns, and is approximately half that width; hence it may either be very long or almost coccoid. It is nonmotile and non-spore forming and is characterized by a thick, well developed capsule, which can be demonstrated by the ordinary Gram stain. It is aerobic and facultative

8. Miss Sylvia Barteau, record librarian of Bellevue Hospital, was helpful in obtaining these records.

While the number of cases in which this was done is few, the uniformity of the results enhances the value of the data. Moreover, in the great majority of cases in which bacteremia was present, this was not terminal or agonal but was present at the height of the disease. Furthermore, in nearly all the cases the Friedländer bacillus was isolated without difficulty from the sputum or lung juice or both when the case first came under observation, usually early in the disease.

As far as could be ascertained, in none of this series was the Friedländer bacillus a secondary invader entering a lung that was already the site of pneumonia due to another organism. This is attested by the fact that in only two instances (cases 3 and 4) was another organism found associated with the Friedländer bacillus, and adequate data are presented in the protocols of these two cases to show that the primary cause of the pneumonia was Friedländer's bacillus and that the other organisms were either mouth contaminants or secondary invaders.

#### REPORT OF CASES

The following are the protocols of ten representative cases that illustrate the main features described in the text of this report:

CASE 1.—A white man, aged 63, while sleeping in an empty warehouse was awakened at 4 a. m. by a chill followed by sharp pain in the left side of the chest when breathing. He coughed and raised a thick bloody, mucoid sputum. He was admitted to the hospital on the third day of the disease, appearing undernourished, pale, cyanotic, dyspneic, and critically ill. Fluoroscopy showed lobar consolidation of the left upper lobe, though the physical signs were limited to dulness and muffled breath sounds over this area. The sputum was a thick, homogeneous, brick-red emulsion of blood and mucus. A smear stained by Gram's method showed numerous polymorphonuclear cells and many bacteria, the predominating organism being large gram-negative encapsulated rods. Examination of a concentrated sample of sputum showed no tubercle bacilli. Mouse inoculation yielded a pure culture of Friedländer bacillus type A from the peritoneal cavity and the heart's blood of the mouse, and this was repeated on the following day with the same result. A lung puncture on the fourth day of illness showed Friedländer's bacillus type A. A blood culture on the same day was sterile, but on the following day there were six colonies of B. Friedländer type A per cubic centimeter of blood. Agglutinins against the infecting organism were absent throughout the illness. The white blood cells on the fourth day numbered 5,100 with 75 per cent polymorphonuclears, of which 62 were immature forms, 15 per cent lymphocytes, 9 per cent monocytes and 1 per cent basophils. On the fifth day the white cells numbered 2,100, with 84 per cent polymorphonuclears, of which 80 were immature forms, 10 per cent lymphocytes, 4 per cent monocytes and 2 per cent basophils.

The illness ran a rapid and virulent course, though the temperature remained persistently below 102 F., and on the fourth day pulmonary edema developed. On the fifth day specific anti-Friedländer serum was obtained and administered, although the patient was moribund, and he received only 20 cc. of serum. He soon relapsed into pulmonary edema and died on the fifth day.

Necropsy showed consolidation of the left upper lobe in a stage of gray hepatization, the lung weighing 1,850 Gm. On the cut surface of the lung was a sticky, slimy exudate which stuck to the knife. Culture of the consolidated lung showed Friedländer's bacillus type A. The unconsolidated parts of the lungs were congested and edematous and there were a few scattered patches of consolidation in both lower lobes. Microscopically, in the consolidated lobe, the alveolar walls were necrotic in areas, and the alveoli were distended with an exudate consisting of polymorphonuclear cells, mononuclear cells, degenerated red cells and gram-negative bacilli. The spleen was enlarged and congested. The gallbladder was small and contracted, containing a few stones. Culture of the bile showed only *Bacillus coli*.

CASE 2.—A white man, aged 58, stated that illness began suddenly with chills and fever, sharp pains in the right side of the chest, vomiting and diarrhea. He coughed and raised bloody sputum. He was admitted on the fourth day of illness appearing acutely ill, dyspneic, cyanotic and slightly jaundiced, with a temperature of 105.6, pulse 100 and respiration rate 30. There were signs of consolidation of the right upper lobe. The sputum was thick, mucoid and brick red, and a direct smear showed the presence of gram-negative encapsulated rods. Sputum typing by the rapid Sabin<sup>23</sup> method yielded a pure culture of Friedländer's bacillus type A in two hours, and this was later confirmed by a culture of the heart's blood of the mouse. A lung puncture done a few hours after admission showed Friedländer's bacillus type A. The blood cultures on the fourth and fifth days were sterile, but on the sixth day there were 4 colonies of Friedländer's bacillus type A per cubic centimeter of blood. Serum agglutinins were absent on admission but appeared on the fifth day following serum therapy and persisted till death. The urine showed the presence of albumin and granular casts, but stool and urine cultures were negative for Friedländer's bacillus. The white cells on admission were 2,200, with 48 per cent polymorphonuclears, of which 46 were immature forms, with 21 per cent monocytes, 30 per cent lymphocytes and 1 per cent basophils. On the fifth day the white cells numbered 2,300, with 79 per cent polymorphonuclears, of which 67 were immature, with 4 per cent monocytes and 17 per cent lymphocytes. The jaundice increased and shortly before death the icteric index reached 50.

Serum administration was begun a few hours after admission, the patient receiving a total of 400 cc. of serum intravenously within forty-eight hours. At the same time pneumothorax treatment was employed, it being felt that in so hopeless a disease the patient's welfare would not be jeopardized; a total of 800 cc. of air was given. The clinical course was characteristically rapid and fatal. On the sixth day pulmonary edema and tympanites developed, followed by the appearance of petechiae in the conjunctiva, death occurring soon after. Permission for necropsy was refused.

CASE 3.—A white man, aged 54, stated that illness began the day before admission with a vomiting spell, followed by sharp pain in the right side of the chest, chills, fever and cough with rusty sputum. The patient was cyanotic, dyspneic and acutely ill on admission, with a temperature of 102 F. Physical examination and fluoroscopy revealed a lobar consolidation of the right middle lobe. The sputum on admission was thick brown and viscid, and when it was typed a pure growth of Friedländer's bacillus was found. When this was repeated ten days later, however, the peritoneal washings showed Friedländer's bacillus and *Streptococcus viridans*, but from the heart's blood of the mouse a pure culture of Friedländer's bacillus was obtained.

Cultures of the patient's blood resulted in some unusual observations. On the third day of illness the blood culture was sterile, but on the fourth and fifth days the broths showed the presence of Friedländer's bacillus, the agar plates having no growth. On the sixth day there were six colonies of Friedländer's bacillus per cubic centimeter of blood, together with one colony of pneumococcus type I. On the seventh day again there was only Friedländer's bacillus, one colony per cubic centimeter of blood. On the eighth day there were two colonies of Friedländer's bacillus per cubic centimeter of blood and two colonies of diphtheroids per cubic centimeter of blood. On the ninth day the plates were sterile but the broth showed Friedländer's bacillus and a diphtheroid. The culture was sterile on the tenth day, while on the eleventh day the broth showed a growth of *Streptococcus viridans*. Thereafter on the twelfth and thirteenth day the cultures were sterile. Serum agglutinins for the Friedländer bacillus were about throughout, but for the pneumococcus type I they were present for a brief time on the fourth and fifth day. The white cell count on admission was 9,200, with 95 per cent polymorphonuclears, of which 81 were immature forms and 5 per cent were lymphocytes. Serial counts showed fluctuations with a general tendency to increase in leukocytosis, and on the day of death the count reached 23,300, with 98 per cent polymorphonuclears, of which 91 were immature forms and 2 per cent lymphocytes. The temperature ranged between 100 and 104 F. with wide diurnal swings, and the patient showed alternating peri-

age in this group ranged from 25 to 75 years, the mean being 48.7 years. Examination of the accompanying chart reveals that twenty-two (68.7 per cent) of the patients were either in the fifth or the sixth decade of life. This finding coincides with that noted by other authors. It is rare in children, although a few cases have been reported.<sup>20</sup> According to Dr. Charles Hendee Smith,<sup>10</sup> director of the Children's Medical Division of Bellevue Hospital, only one questionable case has been noted in his service among approximately 2,000 typed pneumonia cases in the past eight years.

There were twenty-eight males and four females in the group, a ratio of seven to one. This marked preponderance of males is only partly explained by the greater number of males admitted to the hospital; it must in large measure be due to other factors, such as exposure and increased opportunity for contact. Twenty-nine of the patients were white and three were Negroes, but it is probable that the foregoing disparity in incidence may be due to some extent to the fact that acutely ill Negroes are generally hospitalized in their own district, chiefly in Harlem and Lincoln hospitals.

#### PREDISPOSING FACTORS

That certain predisposing factors play a rôle seems very likely. Cold and exposure appear to be contributory and were noted in fifteen of the case histories (47 per cent). The pronounced seasonal incidence is additional evidence for this opinion, twenty-one (65.6 per cent) of the cases occurring in the six months from November to April inclusive, as compared with only eleven cases for the remaining six months. This is at variance with the observations of Bhatnagar and Singh,<sup>21</sup> who in a small series of cases report a preponderant incidence during the hot summer months. Alcoholism has come under suspicion as a predisposing factor more particularly in this than in other forms of pneumonia. Support is lent to this view by the fact that in seventeen cases there was a history of chronic alcoholism, an incidence of approximately 53 per cent. Malnutrition and other debilitating factors were noted in fifteen cases (47 per cent). It would be wrong to suppose, however, that this disease is restricted to any economic stratum.

It seems of value also to inquire regarding the rôle of antecedent respiratory disease. Six patients had had pneumonia previously, eight others gave a history of chronic bronchitis or pleurisy, and eight suffered from chronic infections of the upper respiratory tract, including several in whom an infection of the upper respiratory tract immediately preceded the pneumonia. The latter fact is noteworthy in view of the occasional discovery of the Friedländer bacillus in the upper respiratory tract and raises the question whether the pneumonia might not be secondary to a descending infection. In this connection it was noted that the majority of the patients had foci of infection in the upper respiratory tract such as dental caries, pharyngitis or diseased tonsils and sinuses, though these were not cultured.

Occupation apparently plays little part in predisposing to this disease, as a great variety of trades and vocations were represented, including laborers, sales-

men, bartenders and housewives. Three of the patients were miners and showed evidence of silicosis as well as pneumonia.

#### CLINICAL COURSE

Friedländer's pneumonia usually begins abruptly, this type of onset being noted in twenty-four (75 per cent) of the cases. In the remainder there were prodromes such as general malaise, anorexia and infection of the upper respiratory tract preceding the onset of the pneumonia. The disease was ushered in by a chill in twenty instances (62.5 per cent), and there was sharp pleuritic pain in twenty-seven cases (85 per cent). Cough, generally productive, was an initial symptom in twenty-six cases (81 per cent), being associated in a striking manner with hemoptysis in twenty-four instances (75 per cent). Gastro-intestinal symptoms such as vomiting and diarrhea were initial symptoms in nine cases (28 per cent), and systemic manifestations such as general malaise, fever, aches and pains occurred practically invariably with the onset. The day of disease on admission to the hospital varied from the first to the thirteenth day, the average being between the third and the fourth day, in those cases in which the pneumonia developed prior to admission. Four of the patients were admitted for other conditions, pneumonia developing while they were in the hospital.

Clinically the patients appeared acutely ill, dyspneic and cyanotic, so that it was not difficult to surmise that they were suffering from pneumonia. Herpes was uncommon but not as rare as some authors believe. Schlapper<sup>22</sup> for example states that herpes, which is the rule in pneumococcic pneumonia, has not yet been described in this disease. It occurred in four cases of this series (12.5 per cent), all of which were fatal; this is in contrast to the favorable prognostic significance that herpes is said to have in pneumococcic pneumonia. Jaundice occurred in seven cases (approximately 22 per cent), all of which were fatal. Herpes and jaundice did not occur together in any case. Petechiae were noted on the mucous membranes or skin in three fatal cases, occurring in each at a time when bacteremia was present.

The temperature was variable, ranging from 100 to 106 F., and in one case complicated by meningitis it reached as high as 109 F., which is not rare in terminal meningitis. Usually it was somewhat irregular, with moderate fluctuations in twenty of the thirty-two cases. In the remaining twelve the temperature was totally irregular with marked diurnal variations, usually because of some complication such as abscess formation, empyema or meningitis. In the one case in which recovery occurred the fall was by crisis on the tenth day. Etienne<sup>14</sup> and Belk<sup>18</sup> emphasize the fact that in Friedländer's pneumonia in spite of the fact that the patients appear desperately ill, the fever rarely rises above 102 F. This feature was noted in sixteen cases (50 per cent) and, though it is not as constant a finding as Etienne and Belk believe, nevertheless it is much commoner than in pneumococcic pneumonia.

The clinical course was generally fulminating. Thirty-one of the thirty-two patients died, a mortality rate of approximately 97 per cent. Death occurred from the second to the sixteenth day, the average day of death being between the sixth and the seventh day of illness, fatal termination being usually preceded by pulmonary edema.

21. Bhatnagar, S. S., and Singh, K.: *Bacteriological Studies in Acute Lobar Pneumonia Due to Pneumococcus and B. Pneumoniae Friedländer*, Indian J. M. Research 23: 337 (Oct.) 1935.

22. Schlapper, K.: *Ueber Friedländer-Pneumonien*, Beitr. z. Klin. d. Tuberk. 78: 741, 1931.

At necropsy the right lung weighed 1,800 Gm. Consolidation was limited to the lower part of the right upper lobe, the entire right middle lobe and the upper part of the right lower lobe. The consolidated areas appeared reddish gray, and a sticky, slimy, brown exudate was present on the cut surface. There was a thin, yellow effusion of about 300 cc. in the right pleural cavity. Culture of the effusion and the lung at autopsy showed pure growth of Friedländer's bacillus type A. The spleen weighed 95 Gm. and appeared normal, but culture of it also showed Friedländer's bacillus type A. The liver weighed 2,800 Gm. and was fatty, but the biliary tracts appeared normal. Culture of the bile and contents of the kidney pelvis were sterile. No other abnormalities were noted.

CASE 9.—A white man, aged 43, an unemployed miner, was homeless and slept outdoors. The next day he had severe pains in the chest, cough with bloody sputum, and diarrhea. On admission on the third day he appeared emaciated, acutely ill, dyspneic and cyanotic. There was clubbing of the fingers and congestion of the pharynx. Physical signs were doubtful, but fluoroscopy showed consolidation of the right upper and middle lobes. The sputum was characteristic, appearing thick, mucoid and bloody, and a direct smear showed large gram-negative encapsulated rods. Sputum typing showed Friedländer's bacillus type A, and this was confirmed by lung puncture. Repeated examinations of the sputum showed no tubercle bacilli. The blood culture on admission showed growth in the broths of Friedländer's bacillus type A. On the fourth day there were ten colonies per cubic centimeter of blood, and on the fifth day this increased to 110 colonies. The white count on the third day was 18,800, with 96 per cent polymorphonuclears and 4 per cent lymphocytes. On the fifth day the count fell to 4,600, with 90 per cent polymorphonuclears, of which 62 were immature forms, 7 per cent monocytes and 3 per cent lymphocytes.

The temperature was irregular, ranging from 99 to 102. Specific serum was started a few hours after admission, a total of 230 cc. being given in three days. Agglutinins against the infecting organism, which were absent on admission, appeared in the patient's blood on the fifth day and persisted till death. There was no apparent effect, however, on the downhill progress of the patient. Herpes appeared on the fourth day, and consolidation spread to involve the entire right lung. Death occurred on the sixth day.

At necropsy the entire right lung was consolidated, weighing 3,720 Gm. The right lower lobe was solid, mottled and covered with a thick, sticky brown exudate, which on culture showed Friedländer's bacillus type A. There was liquefaction necrosis of the entire right upper and middle lobes, with a peculiar odor resembling hydrogen sulfide. The left lung was congested. The spleen was also congested and soft, weighing 150 Gm. No other abnormalities were noted.

CASE 10.—A Negress, aged 54, during the course of treatment with arspenamine, developed jaundice, pruritus and vomiting. On admission she appeared acutely ill, lethargic and jaundiced, with a temperature of 102.6. The skin was dry and scaly, and the pharynx was congested and membranous. The lungs were clear on admission, save for decreased resonance at the right base. The diagnosis on admission was toxic hepatitis (arsenical).

Five days after admission the patient complained of pain in the right side of the chest and there were signs of frank consolidation of the right lower lobe. She coughed and raised a thick, mucoid, bloody sputum, smear of which showed large gram-negative encapsulated rods. A sputum typing showed Friedländer's bacillus type A, and this was confirmed by lung puncture. The blood culture was sterile. The white count shortly after admission was 6,300, with 62 per cent polymorphonuclears, 24 per cent lymphocytes and 14 per cent monocytes. The day after the onset of pneumonia the white count was 5,100, with 81 per cent polymorphonuclears, of which 21 were immature forms, 10 per cent lymphocytes, 8 per cent monocytes and 1 per cent eosinophils. The temperature was irregular, ranging from 101 to 104. The clinical course following the onset of pneumonia was fulminating. Consolidation spread to the left lower lobe, and death occurred on the third day of the pneumonia.

At necropsy there was consolidation of the right lower lobe and the left lower lobe. The cut surface of each of these involved lobes appeared grayish brown and soft, being covered

by a slimy, brown, mucoid exudate. Culture of the right lower lobe showed Friedländer's bacillus type A. At the right apex there was a small obsolete tuberculous focus. The remainder of both lungs was edematous and congested. The liver weighed 2,000 Gm. and was soft, friable and fatty. Ascites was present, there being approximately 400 cc. of amber fluid in the peritoneal cavity. No other pathologic changes of note were observed.

#### SUMMARY AND CONCLUSIONS

1. In twenty-seven of thirty-two cases of primary Friedländer's pneumonia (84 per cent) the involvement was lobar; in the remainder it was bronchopneumonic. As in other pneumonias, certain predisposing factors play a rôle, such as exposure, malnutrition, debility, alcoholism and antecedent diseases of the upper respiratory tract. The onset is generally acute with chill, fever, cough and pleuritic pain. Clinically, the patients appear acutely ill, dyspneic and cyanotic, and there is a fulminating course.

2. This study reveals certain features which serve to distinguish Friedländer's pneumonia from other forms:

(a) It occurs in the later decades, the average age being 48.7 years.

(b) There is a marked preponderance of males over females, the ratio being 7 to 1.

(c) Hemoptysis is a frequent symptom with the onset (75 per cent).

(d) Herpes is not common (12.5 per cent); jaundice is rather frequent (22 per cent).

(e) In approximately half the cases the frank clinical signs of consolidation are absent when symptomatology suggests it and roentgenograms, fluoroscopy or necropsy confirms it.

(f) The temperature is less regular and low grade pyrexia is much more common than in pneumococcal pneumonia.

(g) There is frequently involvement of the upper lobe. This occurred alone or in conjunction with lower or middle lobe involvement in nineteen cases (59.4 per cent). Involvement of more than one lobe is very frequent. It was noted in eighteen cases (56 per cent).

(h) The gross character of the sputum is that of a brick red, homogeneous emulsion of blood and mucus, in contrast to the ropy, rusty sputum of pneumococcal pneumonia. A direct smear of the sputum stained by Gram's method will usually show a predominance of large gram-negative bacilli with a refractive zone around them representing the capsule. Mouse inoculation will invariably confirm the diagnosis. The character of the sputum is pathognomonic and has hitherto not been described in detail.

(i) The Friedländer bacillus is found in pure culture in the sputum, in lung juice and frequently in the blood culture.

(j) Leukopenia with a "shift to the left" in the Schilling index and monocytosis are frequent.

(k) The mortality rate is very high (97 per cent in this series). Death occurs at an earlier stage in this disease than in pneumococcal pneumonia, the average day of death being between the sixth and seventh days. Death may be attributed to general toxemia and marked pulmonary necrosis, with local vascular changes and pulmonary edema.

(l) Bacteremia is more frequent (73 per cent) but is quantitatively less intense. The mortality rate is apparently little affected by the absence of bacteremia.

(m) Gross abscess formation is the most frequent complication. Empyema and meningitis are less common, and Friedländer's bacillus can be readily cultured from the pus and spinal fluid in these cases.

to belong to group A. The day of onset of bacteremia as far as could be ascertained varied from the second to the ninth, the average being between the fourth and the fifth day of illness. Of the eight patients who had sterile blood cultures, seven died, a mortality rate of approximately 87.5 per cent. This high mortality in cases without bacteremia is surprising and contrasts sharply with the low mortality rate in corresponding groups of pneumococcic pneumonia.

A further analysis of the degree of bacteremia yields some surprising information. Of the nineteen cases presenting positive blood cultures, in six there was growth only in the broth, the agar plates being sterile; in nine cases there were less than 50 colonies per cubic centimeter of blood; in two the number of colonies ranged around 100 per cubic centimeter of blood, and in the remaining two cases the colonies were innumerable. In other words, in fifteen of the nineteen bacteremic cases (79 per cent) the blood stream invasion was minimal or mild.

Two salient facts appear in considering these data. First, the high mortality rate (87.5 per cent) in the nonbacteremic group; second, the mild degree of blood stream invasion in the bacteremic group. It seems logical to assume from the foregoing that, in pneumonia due to Friedländer's bacillus, bacteremia apparently does not play the major rôle in the cause of death. This is in contrast to pneumococcic pneumonia, in which the mortality rate varies directly as the incidence and severity of bacteremia. The cause of death in Friedländer's pneumonia is obscure in the absence of complications. It cannot be ascribed to bacteremia or to cardiac failure, as far as can be determined. In the cases that were studied with this in mind, the heart action appeared good throughout. The pulse pressure was well maintained and there was no abnormal rise in venous pressure even when the patient was moribund and showed pulmonary edema. It is a fair assumption that death is due in large part to a severe general toxemia combined with intense pulmonary reaction to the organism, resulting in local necrosis and local vascular changes with resulting pulmonary edema.

#### BLOOD CELL CHANGES

White cell counts were done in twenty-four cases, in fourteen cases serial counts being obtained. The total white counts ranged from 1,800 to 31,800. In six cases (25 per cent) the white count never exceeded 6,000, and in nine others it ranged between 6,000 and 12,000. In six it ranged between 12,000 and 20,000 and only in three did it ever exceed 20,000. Thus it is seen that in fifteen cases (63 per cent) there was an absolute or a relative leukopenia. It should be remembered that these figures deal with the highest white count reached in the given cases. It might be added that there were in addition five other cases in which the count at some time went below 6,000, and four more in which the count at some time went below 12,000. Thus there was a total of eleven cases (45.8 per cent) with absolute leukopenia at some stage of the disease. It seems likely that if serial white counts had been done as a routine the proportion might have been still higher.

It is of interest to note the effect of complications on the total number of white cells. In two cases of empyema the count reached 12,000 and 30,500 respectively. In six cases of abscess formation the highest counts were 18,800, 18,700, 31,800, 12,000, 9,000 and 6,600 respectively. In one case complicated by meningitis the white cells numbered 15,200. In another the count was 3,800 before the onset of meningitis, no count being taken after this event, which was terminal.

These observations lend support to the view that in uncomplicated cases of Friedländer's pneumonia there is a tendency to an absolute or a relative leukopenia. It is noteworthy that there was a distinct leukocytosis (22,700 white cells) in the only case in which recovery occurred. In fourteen cases in which serial observations were made in the course of the disease, in eight the total count showed a tendency to rise, in four to fall, and in two to remain stationary.

An analysis of the differential white counts shows that the polymorphonuclear leukocytes ranged from 48 to 98 per cent with immature forms constituting from 31 to 91 per cent of the total white cells. The monocytes ranged from 0 to 34 per cent of the white cells. There were in all ten cases (42 per cent) presenting monocytes exceeding 4 per cent of the total count, including five cases in which they exceeded 8 per cent. In general the blood picture was that of an increase in the polymorphonuclear leukocytes, with usually a high percentage of immature forms. In 42 per cent of the cases there was an increase in the circulating monocytes, but only in 21 per cent was this of a marked degree.

The red cells were as a rule within normal limits, although in some cases there was a moderate secondary anemia. There did not, however, appear to be any increasing anemia indicative, for example, of a hemolytic action of the Friedländer bacillus.

#### COMPLICATIONS

Complications in this series were as a rule limited to the chest. In six cases there was a gross necrosis of the lung tissue, with sloughing and cavitation. This appeared as early as the fifth day in one instance, although Apelt<sup>24</sup> and Belk<sup>28</sup> each report a case in which abscess formation was noted on the fourth day. In the remaining cases of this series the pulmonary necrosis occurred as far as could be determined on the eighth, ninth, tenth and eleventh days respectively. Usually the diagnosis was made at necropsy, as foul sputum was observed in only two cases. Hence as only approximately half the patients who died came to autopsy it is reasonable to assume that this was a more common occurrence than these figures indicate. Empyema was noted in two cases, the Friedländer bacillus being isolated in pure culture from the pus in both instances. Pleural effusion occurred in six cases, though in only two was it marked (greater than 400 cc.). A purulent Friedländer bacillus pericarditis was noted in one case at necropsy, this condition not having been diagnosed during life.

Meningitis occurred in three cases, all ending fatally and in each, cultures from the spinal fluid yielded the Friedländer bacillus. The character of the spinal fluid is described in the protocol of case 4. Secondary infection with other organisms was noted in one case (case 3) in which two days after the recovery of the Friedländer bacillus in the sputum and blood the blood culture showed pneumococcus type I and diphtheroids in addition to the Friedländer bacillus. This was followed later by invasion of the blood with *Streptococcus viridans*. That this can occur in pneumococcic pneumonia was pointed out in a previous communica-

24. Apelt, F.: Ueber die durch den *Bacillus pneumoniae*: "Friedländer" hervorgerufene Pneumonie, München. med. Wchnschr. 55: 833, 1908.

because of anuria for four days. In August 1935 the right kidney had been removed by Dr. Harvard H. Crabtree for tuberculosis.

Dec. 31, 1935, fever and signs of pneumonia developed. The pneumonia was of moderate severity, involving the left lower lobe and later the right upper lobe. His temperature reached 102.6 F. He perspired so profusely that the bed clothing had to be changed several times a day. He took such fluids as

The morning urine was cloudy and contained a small amount of pus, and an infection of the kidney was feared. However, the specimens usually became clear during the day. He was given 80 grains (5.2 Gm.) of methenamine daily by mouth. His temperature was 100 F. at its height each day during the first two weeks. On each occasion when he received 20 per cent salt solution a marked chill followed from forty-five minutes to an hour after the injection.

fruit juices, coffee, tea and water very freely, up to 5,250 cc. a day. Suddenly on the third day he became anuric and at the time of his admission to the Deaconess Hospital no urine had been obtained for four days, with the exception of one-half ounce (15 cc.) on one occasion.

On admission the blood pressure was 100 systolic, 60 diastolic. The pulse was regular and the rate was 84. The skin was not very dry, although the tongue was dry, and he was somewhat delirious. Cheyne-Stokes respiration developed. The

TABLE 3.—Red Cells and Plasma Protein Values for Case 2

blood sugar was 0.13 per cent. Table 1 summarizes the analyses of the nonprotein nitrogen of the blood and of the plasma chloride.

The fall in blood nitrogen and the rise in plasma chloride was accompanied by a diuresis. At 8 p. m., January 7, about fourteen hours after admission, 9 ounces (270 cc.) of urine was obtained by catheter. January 8, 30 ounces (900 cc.) was obtained, and the next day 90 ounces (2,700 cc.) was obtained. From that time on recovery was uneventful, although his mental condition did not become entirely clear until January 12, when the blood pressure was 148 systolic, 88 diastolic. He weighed 148 pounds (67 Kg.) net January 20; 148 pounds (67.6 Kg.) January 24 and 151 pounds (68.5 Kg.) January 27.

In tables 2 and 3 are shown data for the concentration of protein in the blood plasma, the red cell count and the course of the urinary nitrogen and chloride during recovery.

According to a report from his family physician, the patient was in good condition Dec. 25, 1936.

## COMMENT

Comparison may be made between this group of patients in whom anuria was promptly relieved by the intravenous use of hypertonic salt solution with those having heat cramps, studied by Talbott.<sup>2</sup> Under conditions of extreme muscular exertion, high temperature and extreme sweating, Talbott found a reduction of inorganic base in the patient's serum, chiefly in the sodium fraction, and a reduction of the acids, chiefly in the chloride fraction. This decrease in the serum electrolytes he considered the principal causative mechanism in the production of heat cramps. The critical time at which muscle cramps occur he considered to be a matter of individual susceptibility. The patients showed high degrees of concentration of the protein of the serum and hemoglobin of the blood, which decreased under treatment. The nonprotein nitrogen content of the serum was usually increased and in one case was 106 mg. per hundred cubic centimeters. None of the cases presented anuria. Possibly men engaged in such work would have sounder hearts and kidneys than those of an older group not capable of engaging in such occupations. The fact that nitrogen retention occurred.

2. Talbott, J. H.: Heat Cramps, *Medicine* 14: 323 (Sept.) 1935.

exposure as important predisposing factors. Apelt<sup>24</sup> in 1908 reported seven deaths, the average age of the patients being 50 years; among this group there were two cases of lung abscess.

Sisson and Thompson<sup>31</sup> in 1915 reviewed the entire literature on the subject and concluded that only thirty-three cases could be strictly accepted as genuine examples of primary Friedländer's pneumonia. To this number they added four of their own. One case ran a chronic course with recovery after empyema with Friedländer's bacillus had developed. The other three patients died within the first week, in one instance death occurring thirty-two hours after the onset. This is one of the most fulminating cases on record, being second only to one reported by Fremmel, Henrichsen and Sweaney,<sup>32</sup> in which death occurred in six hours.

In 1919 there appeared a paper by Zander,<sup>6</sup> reporting an outbreak in a labor camp in Germany during the World War. This article is discussed in some detail here mainly because of the large number of cases, a total greater than that in the entire remaining literature. There were 411 cases with 144 deaths, a mortality rate of only 35 per cent, which Zander strangely enough states is extremely high, though all other authors agree that the usual mortality rate is over 90 per cent. The average age of his group was 25 years. The pneumonia began in the lower lobes and at first was lobar, later becoming bronchopneumonic in distribution, Zander states. The duration of fever averaged 9.5 days, and empyema occurred in twenty cases. In addition, the author goes on to say, a number of the cases "developed into pulmonary tuberculosis."

A critical analysis of this series raises grave doubts as to whether they were true cases of Friedländer's pneumonia. There is no mention of sputum typing, blood cultures or agglutination tests, and there is no record of any necropsies on the fatal cases which might have afforded valuable confirmatory evidence. Moreover, the mild clinical course and low mortality rate distinguish these cases from all other instances of Friedländer's pneumonia reported either before or since.

Among the more important contributions is that of Belk,<sup>18</sup> who in 1926 reported eighteen cases, all of which were fatal. Half of his group may be regarded as true instances of primary Friedländer's pneumonia, the remainder being cases of mixed infection. The temperature was generally irregular and seldom higher than 102 F. Abscess formation was common, in one case occurring as early as the fourth day of illness. Belk conveniently classified his cases into three groups: terminal lobular pneumonia, primary lobar pneumonia and chronic suppurative pneumonia. Stengel, Kornblum and Collins<sup>33</sup> in 1928 reported three cases, paying particular attention to the x-ray appearance of the pulmonary lesions.

Ferguson and Tower<sup>16</sup> in 1933 reported the occurrence of Friedländer's pneumonia in two infants aged 7 months, an exceedingly rare occurrence at this age. Only two other cases have been reported in children, one by Etienne<sup>14</sup> and one by Comba.<sup>20</sup> Olcott<sup>34</sup> in

1933 reported six fatal cases, calling attention to the frequency of leukopenia and monocytosis and also discussing the pathology. Stoichita and Jonnesco,<sup>35</sup> in 1933 observed a fatal lung abscess due to the Friedländer bacillus occurring two days after tonsillectomy.

Abrami and Worms<sup>36</sup> in 1930 reported a case in which recovery occurred following the administration of intravenous injections of acriflavine. They also quote a case of Chirie's with Friedländer's bacillus bacteremia which was cured apparently by colloidal gold treatment, and one of Pic and Durand that was cured with vaccine therapy. However, any conclusions regarding the foregoing therapeutic agents are unwarranted both because of the paucity of the cases and because of the fact that instances of spontaneous recovery are well known to occur.

As stated previously, the rôle of the Friedländer bacillus in pneumonia is still disputed. It is contended by some that this organism, when present in cases of pneumonia, is merely a secondary invader. This view is strongly championed by Baehr, Schwartzman and Greenspan<sup>37</sup> in a recent communication. They maintain that the organism is concerned chiefly with infections of the biliary system, the genito-urinary system and perforative lesions of the intestinal tract. When encountered in pneumonia they believe it is seldom, if ever, the primary cause of infection but that it is either a secondary invader or has reached the lung from the intestinal tract, the bile passages or the urinary tract by way of the blood stream or by direct extension. These authors state further that "the error in the original publication of Friedländer and in most of the subsequent publications can be ascribed to the fact that the bacteriological observations were only made post mortem. Preagonal and postmortem invasion of the blood stream is common, the organism invading the body from the intestinal tract in common with other organisms of the intestinal flora, and therefore often reaching the lungs which are the site of disease due to other bacteria."

A critical study of the present series of cases leads me to believe that this conception is in the main untenable. As stated previously, while it is admitted that the Friedländer bacillus is occasionally found as a secondary invader in pneumonia, nevertheless sufficient evidence has been adduced to warrant the assertion that this organism is by no means a rare cause of primary pneumonia. If Friedländer's pneumonia is a metastatic manifestation of an infection with this organism elsewhere in the body, it is reasonable to expect that invasion of the blood stream precedes its localization in the lung. Yet in seven cases the organism was found in the sputum, this being confirmed by lung puncture in four cases from one to eight days before it was found in the blood stream. In still six other cases the bacillus was found in the sputum or lung puncture or both, while the blood cultures remained sterile throughout the illness. Moreover, biliary, genito-urinary or intestinal lesions were noted in only four cases. In two of these four cases, and in four others in which cultures of the renal pelvis and gallbladder contents were taken at necropsy, Friedländer's organisms were not found.

few weeks involved his hands, head, face, abdomen and chest. These were portions of the body never before involved. Also the character of the lesions changed. Some were more "heaped up." Others were noticeably red in spots or else "weaped" serous fluid. A few seemed to contain pus.

Malaise and sensations of chilliness and weakness accompanied these skin changes and forced the patient to bed. Within a few weeks arthritic manifestations appeared, rapidly spread-

Fig. 1.—Appearance during the second week of treatment. Some of the skin lesions had already cleared. The arthritic swelling of the hands, knees and ankles is striking. Several typical psoriasiform lesions can be seen on the legs.

ing to involve the knees, ankles, elbows, wrists and bones of the hands. These joints became swollen, painful and limited in motion. The patient remained bedridden. A low grade fever was noted. Because of the failure to improve at home, the patient was referred to the hospital.

**Examination.**—The patient was poorly nourished, was in obvious distress, and was unable to walk or stand without support. The following significant facts were noted: The lower teeth were carious, with the gums spongy and infected. The tonsils were atrophic. The blood pressure was 138 systolic, 74 diastolic. Pulse and respirations were normal. The heart and lungs were normal.

The cervical, axillary, epitrochlear and inguinal lymph nodes were palpable, firm, pea sized and not tender. The prostate was small, not tender and firm. The genitalia were normal.

The knees, ankles, elbows, wrists and bones of the hands were involved. Each joint was swollen, tender and slightly warm to the touch. Mobility was limited and painful. A slight sensation of crepitation was noticed when some of the joints were forcibly moved. Slight muscular atrophy was present about the more severely involved joints (fig. 1). There was some edema of the feet.

Except for the face, palms and soles, most of the body was covered with psoriasiform lesions. The nails of the fingers and toes were involved. The lesions consisted of confluent circular or oval patches of silvery wrinkled scales with elevated edges. Erythematous areas were prominent about some lesions. On the hands and feet were a few atypical heaped up crusted lesions, looking somewhat pustular. No moist lesions were present.

The temperature varied from 97.6 to 99.4 F. Weekly urine and renal function tests were consistently normal. White blood

counts varied from 7,000 to 12,000. The hemoglobin on admission was 64 per cent (Sahli), the red blood count 3,500,000 and the differential count normal. The blood nonprotein nitrogen was 32 mg. per hundred cubic centimeters, with the uric acid 2.2 mg. The total blood protein was 5.5 Gm. per hundred cubic centimeters, with the albumin fraction 2.5 Gm. and the globulin fraction 3 Gm. The sedimentation rate by the modified Westergren method was increased to four times the normal rate. The blood Kahn and Hinton tests were negative. Blood calcium was 10.3 mg. per hundred cubic centimeters, while the phosphorus was 4.6 mg. A Schwartz-McNeil test for gonococcal infection was negative, as was a skin test with gonococcus filtrate. Eight blood cultures were negative.

Roentgenograms revealed a normal heart and chest plate, normal sinus plates and carious lower teeth. Films of the joints showed periarticular swelling, encroachment on the joint space and slight destruction and atrophic changes of the bone (fig. 2). They were interpreted as being consistent with rheumatoid arthritis. An electrocardiogram was normal.

**Course.**—For six weeks various measures directed against the arthritis were tried without success. During this time, little attention or treatment had been directed to the skin lesions. Following the establishment of the diagnosis of psoriatic arthritis and the appreciation of the statement in the literature<sup>3</sup> that the arthritis often subsided if the skin lesions were treated, it was decided to drop all measures directed to the joints and treat only the psoriasiform lesions. The crude coal tar ointment and ultraviolet regimen as outlined by Goeckerman<sup>4</sup> was followed. A 1 per cent ointment was applied to the lesions at night. Each morning the patient was exposed to ultraviolet radiations of gradually increasing intensity and duration. After five weeks of this therapy the skin lesions had practically disappeared.

About the fourth week of this regimen a definite improvement was noticed in the arthritic manifestations. Within two

Fig. 2.—Right hand. Arthritic changes are especially marked in the carpal bones and phalanges. Narrowing of the joint space, atrophy of bone and slight destructive changes can be seen.

weeks after the skin lesions cleared, the arthritis had subsided to such a degree that the patient became ambulatory. The swelling of the joints, tenderness on palpation and spontaneous pain entirely disappeared. A slight stiffness remained on motion.

ods of clinical improvement and exacerbation, finally dying on the thirteenth day. Necropsy was not performed.

CASE 4.—A white man, aged 59, stated that illness began with sharp pain in the right side of the chest followed by cough and bloody sputum. The past history was irrelevant except for the fact that he had been a miner of hard coal for many years and was addicted to alcohol. He was admitted on the third day appearing acutely ill, dyspneic and cyanotic, with a temperature of 104, pulse 130 and respiration rate 40. The pharynx was congested. There were dulness, decreased breath sounds and a few moist râles over the right lower lobe, and the diagnosis of right lower lobe pneumonia was made from fluoroscopy. The sputum was thick, mucoid and brown, and a sputum typing showed Friedländer's bacillus type A and a few type VI pneumococci. Culture of the heart's blood of the mouse revealed Friedländer's bacillus type A in pure culture. The case was considered Friedländer's pneumonia because, in addition, Friedländer's bacillus type A was found in pure culture in the lung juice obtained by lung puncture on the day of admission.

The blood culture on admission showed two colonies of Friedländer's bacillus type A per cubic centimeter of blood. On the fourth day there were approximately thirty colonies per cubic centimeter of blood and on the fifth day the colonies were innumerable. Agglutinins for Friedländer's bacillus, which were absent on the third and fourth days, appeared in the patient's blood spontaneously on the fifth day. Agglutinins for pneumococcus type VI were persistently absent. The white blood cells on the third day numbered 3,250, with 88 per cent polymorphonuclears, of which 80 were immature forms, 4 per cent monocytes and 8 per cent lymphocytes. On the fourth day the white cells numbered 3,800, with 90 per cent polymorphonuclears, of which 80 were immature forms and 10 per cent lymphocytes. The patient appeared extremely toxic throughout his course and jaundice developed, the icteric index reaching 40. The temperature remained between 103 and 104. On the fifth day he showed signs of meningitis and pulmonary edema developed, death occurring soon after. A spinal tap done immediately after death yielded a turbid, faintly yellow fluid, which contained approximately 800 cells per cubic centimeter, chiefly polymorphonuclear leukocytes and gram-negative bacilli. The sugar was decreased, albumin and globulin were increased, and culture of the spinal fluid showed Friedländer's bacillus type A.

Necropsy showed lobar pneumonia of the right lower lobe. The cut surface was a brownish red and was covered with a slimy, thick exudate. Culture of the lung showed Friedländer's bacillus type A. A small fibropurulent exudate was found in the right side of the chest. A few small areas of lobular consolidation were noted in the left lower lobe. The spleen appeared enlarged, soft and mushy. The brain was not examined.

CASE 5.—A white man, aged 54, following exposure to cold, complained of severe pain in the right side of the chest on breathing, cough and bloody expectoration, weakness, nausea, vomiting and constipation. On admission on the seventh day he appeared dyspneic, cyanotic and acutely ill. Labial herpes was present. He coughed considerably, raising a thick red sputum which, when typed, yielded Friedländer's bacillus. There was consolidation of the right upper and right lower lobes. Blood cultures were not taken. The white blood count on admission was 4,800, with 64 per cent polymorphonuclears, 34 per cent monocytes and 2 per cent lymphocytes. On the eleventh day the count reached 12,800, with 85 per cent polymorphonuclears, 8 per cent monocytes and 7 per cent lymphocytes. The temperature was fairly regular, ranging from 100 to 102, and the clinical course was rapidly downhill, tympanites and delirium developing and death occurring on the eleventh day.

Necropsy disclosed a pyopneumothorax with a bronchopleural fistula in the right side of the chest which contained 1,500 cc. of purulent blood stained fluid, culture showing Friedländer's bacillus. The right upper lobe was consolidated and of a deep brown. It contained three yellow necrotic areas in the upper portion and a cavity of 8 cm. in diameter at the base of the upper lobe partly full of a dirty necrotic material and communicating through a perforation with the pleural space. The right lower lobe was consolidated and the right middle lobe was edematous and congested. The cut surface was brownish red and solid and was covered with a thick, brown, sticky exudate. Microscopic sections of the lung tissue stained by

Gram's method showed gram-negative encapsulated bacilli (Friedländer's bacillus). No other pathologic changes were noted.

CASE 6.—An obese white man, aged 53, whose illness began with chills and fever and sharp pain in the left side of the chest followed by cough with brown sputum, was admitted on the fifth day appearing acutely ill and dyspneic, with a temperature of 102.4. The pharynx was congested. There were dulness and numerous moist râles in the entire left lung, with bronchial breathing in the lower half. The sputum was mucoid, slimy and bloody. A smear stained by Gram's method showed a large number of gram-negative encapsulated rods. The sputum was injected into a mouse and one and one-half hours later the peritoneal juice was aspirated, showing a pure culture of Friedländer's bacillus. A blood culture taken on this day showed thirty colonies of Friedländer's bacillus type A. A lung puncture also yielded Friedländer's bacillus type A. The white blood count was 7,700 with 90 per cent polymorphonuclears, of which 85 were immature forms, 4 per cent lymphocytes and 6 per cent monocytes. Agglutinins for the infecting organisms were absent in the patient's blood.

Serum treatment was started two hours after admission and the patient received a total of 110 cc. of serum intravenously. The clinical course was fulminating, delirium and pulmonary edema setting in. Death occurred on the sixth day, less than twenty-four hours after admission. Necropsy showed a consolidation of the entire left lung, which weighed 1,800 Gm. and appeared reddish gray and solid. The cut surface was moist and red and was covered with a gray, mucoid slime. In the left pleural cavity 400 cc. of a thin, brownish red fluid was found which on culture showed Friedländer's bacillus type A. The right lung weighed 800 Gm. and was congested and edematous. Several peptic ulcers were noted in the stomach and duodenum. The spleen weighed 325 Gm. and appeared soft and congested. The liver weighed 2,800 Gm. and appeared fatty. Cultures of the bile and kidney pelvis were sterile. There were no other pathologic changes of note.

CASE 7.—A white man, aged 48, whose illness began with a severe chill, cough and scanty bloody sputum, weakness and sharp pain in the right side of the chest, was admitted on the third day of illness appearing acutely ill, dyspneic and cyanotic, with frank signs of consolidation of the right upper lobe.

Direct smear of the sputum showed a great predominance of gram-negative encapsulated bacilli, and sputum typing showed Friedländer's bacillus. The blood culture was sterile on admission and was not repeated. The white count on admission was 22,700, with 85 per cent polymorphonuclears, 8 per cent lymphocytes, 6 per cent monocytes and 1 per cent eosinophils. The urine showed a trace of albumin and a few hyaline casts. The temperature ranged from 98 to 104, with wide variations. The patient responded favorably to supportive treatment and nursing care, no serum being employed. Crisis occurred on the tenth day, and the lungs were practically clear on the thirteenth day. The patient was discharged as cured on the fifteenth day.

CASE 8.—A Negro, aged 45, had been drinking excessively for four days and the following morning was awakened by a sharp pain in the right side of the chest, fever and cough, with the production of thick, yellow phlegm. Soon after he had a hemoptysis of a cupful of blood. He was admitted on the first day of illness appearing acutely ill, dyspneic and apprehensive. There were dulness, suppressed breath sounds and moist râles throughout the right lung, and fluoroscopy showed consolidation of most of the right lung.

The sputum was characteristically mucoid and bloody and when typed showed Friedländer's bacillus type A. This was confirmed by culture of the lung juice. The blood culture on the morning of the second day of the disease showed thirty-six colonies of Friedländer's bacillus type A. By the afternoon this had increased to 128 colonies. Agglutinins against the invading organism were never present in the patient's blood. The white cells on admission numbered 12,750, with 77 per cent polymorphonuclears, of which 73 were immature forms, 17 per cent lymphocytes, 4 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The red cells numbered 5,300,000 with 90 per cent hemoglobin. The temperature was irregular, varying from 101 to 103 and the clinical course was rapidly downhill. He became delirious and pulmonary edema developed, death occurring on the third day.

short interval (from days to weeks) following a change in the form of the psoriasis. The skin lesions become erythematous, atypically distributed, increased in extent and/or pustular.<sup>17</sup> The arthritis is usually polyarticular and involves both small and large joints. Severe symmetrical involvement of the terminal joints of the fingers and toes has been commented on as common and characteristic.<sup>18</sup> This may occur whether or not the other joints of the fingers and toes are involved.<sup>2</sup> There is also a striking parallelism between the severity of the skin and joint manifestations.

Psoriatic arthritis lasts from weeks to months but may in rare cases persist permanently. The skin lesions usually subside either spontaneously or after appropriate therapy, followed in a few weeks by recession of the arthritic symptoms.

The syndrome may be repeated several times, at yearly or longer intervals. A characteristic feature in most cases is the marked return of joint function after the first or first few attacks. However, permanent joint damage may follow repeated or long standing attacks of this syndrome.

The joint lesions are not characteristic and may resemble either rheumatoid arthritis or osteo-arthritis. The changes vary from slight periarticular swelling to actual destructive lesions. Garrod<sup>19</sup> noted that intermittent hydrarthrosis might occur. A typical joint is swollen, tender and warm to touch and with painful and limited mobility. Ankylosis is rare at the start but may occur later. Zellner<sup>17</sup> believes that the roentgen picture varies and is not characteristic. Narrowing of the joint space, periarticular swelling and slight bone atrophy are common in the early phase. After repeated or long standing attacks, hazy outline of the bone, roughening of the articular surface, destructive changes and occasionally hypertrophic reactions which cause ankylosis may appear.

The severe cases may be ushered in with chills, fever and leukocytosis.<sup>10</sup> Occasionally there may be a generalized adenopathy (secondary to widespread skin involvement). During the onset the patient may be extremely prostrated and forced to bed. If the joint manifestations are severe, prolonged bed rest becomes necessary. Fever is rarely significant after the onset.<sup>17</sup> Laboratory data are equivocal and not distinctive.<sup>17</sup> Bacteriologic study of both skin and blood are nonconclusive. The age in twenty-two case reports studied varied from 30 to 62, averaging 49. Males were afflicted in about 16 per cent of the cases.

#### COMMENT

The pathogenesis of the development of this syndrome is not certain. Adamson<sup>20</sup> and others attempted to show that keratoderma blennorrhagica was a form of psoriasis arthropathica with pustular lesions. This naturally raised the question of the relationship between these two conditions and gonorrheal infection. However, Downing<sup>21</sup> from a study of the literature, was able to conclude that keratoderma blennorrhagica was a distinct clinical entity, definitely related to gonorrheal infection and entirely unrelated to pustular psoriasis

with arthropathy. The presence of active urethritis, history of gonorrhea and a positive Schwartz-McNeil test will enable one to diagnose keratoderma blennorrhagica even though the skin and joint manifestations of the two are quite similar.

Leary<sup>8</sup> feels that there are two possible explanations for psoriatic arthritis. "The arthritis may be due to focal infection, with the psoriatic lesions in themselves acting as foci for the infection in the joints, or it may be due to toxic products absorbed from the lesions." The commonly reported association of pustular psoriasis and arthritis seems to support the focal infection theory. However, Ebert<sup>10</sup> has shown that all attempts to demonstrate a causal organism in pustular psoriasis have failed. In addition, there have been many cases of arthropathia psoriatica reported<sup>15</sup> in which the lesions were not pustular. The parallelism between the severity of the skin and joint lesions seems to support the theory that the arthritis is due to toxic products absorbed from the skin lesions.

Hunt<sup>22</sup> advanced for psoriatic arthropathica the allergic mechanism which Clausen's work suggests exists in the production of rheumatic-like nodules among animals sensitized to streptococci and in rheumatic fever. This theory explains the occurrence of sterile pustular lesions in psoriasis on an allergic basis rather than a direct bacterial infection. According to this theory the exacerbation of the psoriasis and the coincident arthritis can be explained on an allergic mechanism. Hunt<sup>22</sup> feels that trauma, disturbances of the sympathetic nervous system, exhausting conditions, pregnancy, parturition, lactation and the menopause may influence the onset of an eruption of psoriasis. Garrod<sup>19</sup> noted that trauma and menstrual disturbance seemed to influence his cases of psoriatic arthritis.

The rapidity with which the arthritis subsides and the amount of joint function regained are rarely seen in rheumatoid arthritis or osteo-arthritis. They are not specific for this syndrome, since Hench<sup>23</sup> pointed out that similar remissions of joint manifestations occur in rheumatic fever, intermittent hydrops, periarticular fibrositis, gouty arthritis, and arthritis associated with ulcerative colitis, bacillary dysentery and hemophilia. It thus seems that the pathogenesis of this syndrome is still to be settled.

Treatment of psoriatic arthropathica should be directed chiefly to the skin lesions. In addition, bed rest, proper diet and supportive therapy are desirable. Physical therapy is of value when the arthritis begins to subside. Although any standard treatment for psoriasis can be used, the method described by Goeckerman<sup>4</sup> has yielded good results. Early treatment favors the return of good joint function.<sup>24</sup>

An Extraordinary Capacity for Friendship.—Whatever may be said of Sir William Osler in days to come, of his high position in medicine, of his gifts and versatility—to his contemporaries, love of his fellow man, utter unselfishness, and an extraordinary capacity for friendship will always remain the characteristics which overshadow all else.—Cushing, *Harvey: Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

(n) At necropsy the involved lobes have a characteristic appearance, marked chiefly by some degree of softening and necrosis of the lung with the presence of a characteristic, dirty slimy exudate on the cut surface. Culture of the lung, if the necropsy is performed soon after death, yields the Friedländer bacillus and on microscopic section the organisms can be seen as gram-negative encapsulated rods lying in the cells or free in the alveoli.

3. When an attempt was made to type the bacillus isolated from the sputum, lung juice or blood of the patient, a type A organism was found to the exclusion of all other types.

4. Specific antiserum was used in five cases. Treatment appears to be unsatisfactory, though further trial in a larger series is indicated before any conclusions can be drawn.

5. I take issue with the opinion expressed by Baehr and his co-workers<sup>37</sup> that the Friedländer bacillus is a secondary invader in pneumonia and have cited evidence to refute this view.

## THE INTRAVENOUS ADMINISTRATION OF HYPERTONIC SALT SOLUTION FOR ANURIA

IN PATIENTS WITH ONE KIDNEY

HOWARD F. ROOT, M.D.

BOSTON

The development of anuria is always an emergency, but its occurrence in patients who have previously lost a kidney seems hopeless. The causes of anuria are varied, but it is important to remember that, in certain cases of anuria in which great loss of body fluid and diminished concentration of plasma chloride have followed vomiting, excessive sweating or diarrhea without adequate intake of fluid, treatment by the intravenous administration of salt solution has given surprisingly good results. The explanation of this type of anuria is not clear. The presence of fever and infection suggests that the anuria occurred because of abnormal kidney function. However, in the cases of two children previously described,<sup>1</sup> except for temporary renal irritation from diabetic acidosis in one little girl, no evidence of renal disturbance occurred. In none of these cases has medical shock been a factor. The relief produced promptly by the use of hypertonic salt solution, especially in such juvenile cases without evident infection, leaves the impression that the disturbance in kidney function is in some way directly traceable to the abnormal distribution of water and electrolytes in the blood and tissues. The following two cases are reported as illustrations:

### REPORT OF CASES

CASE 1.—*Impaction of ureteral calculus, vomiting and anuria.* A minister, aged 41, admitted to the Deaconess Hospital May 23, 1930, complained that two weeks previously he had had severe pain in the left flank with anuria for twenty-four hours, followed by hematuria for forty-eight hours, which gradually improved. In 1935 the right kidney had been removed because of multiple calculi, a strangulated ureter and infection.

From the George F. Baker Clinic, New England Deaconess Hospital.  
1. Root, H. F., and Henson, P. P.: Postoperative Suppression of Urine Relieved by the Intravenous Injection of Hypertonic Salt Solution, J. A. M. A. 97: 540 (Aug. 22) 1931. Root, H. F.: Anuria Following Diabetic Coma Relieved by Hypertonic Salt Solution, *ibid.* 103: 482 (Aug. 18) 1934.

The admission specimen of urine contained a very slight trace of albumin, no sugar and no diacetic acid, no casts and from 20 to 30 red blood cells and occasional white blood cells per high power field. The phenolsulfonphthalein test showed a 50 per cent excretion of the dye in two hours and ten minutes, and 600 cc. of urine was obtained. The nonprotein nitrogen was 27 mg. per hundred cubic centimeters of blood.

X-ray examination of the urinary tract showed a small stone in the ureter about 4 inches (10 cm.) above the bladder. May 26, cystoscopy was done by Dr. Harvard H. Crabtree. Catheters were passed into the left ureter, but those of all sizes encountered an obstruction about 4 inches above the bladder. Only a few drops of urine were obtained through the catheter.

May 29, attempts to remove the stone through the cystoscope resulted in pulling the stone down to a point about 1½ inches (3.7 cm.) above the ureteral orifices. During these attempts small fragments of stone were obtained. The left ureteral orifice was then split open with scissors, and the ureteral catheter did not pass the stone to allow drainage of the kidney. Following this procedure the patient began to vomit and ceased to pass urine. During the next two days he vomited repeatedly, and by the evening of May 30 his condition was precarious. The temperature had risen to 102 F. and the blood nonprotein nitrogen was 59 mg. per hundred cubic centimeters. It seemed doubtful whether he could stand a major operation to remove the stone directly from the ureter.

Analysis of the plasma chloride showed a value of 430 mg. per hundred cubic centimeters. It seemed possible, therefore, that two conditions were to be reckoned with. In the first place, probably edema around the stone had resulted in complete occlusion of the ureter; the vomiting resulting from this obstruction had produced loss of body fluid and electrolytes. The reduction in plasma chloride represented a reduction in total base. Imminent failure of renal function seemed due in part to back pressure from the obstruction and in part to infection. It seemed possible that the use of hypertonic salt solution intravenously might accomplish two results:

1. It might reduce the edema about the stone so that it could be passed.
2. It might induce urinary secretion by raising the concentration of plasma chloride.

TABLE 1.—*Intravenous Medication and Blood Analyses in Case 2*

Date, 1936	Nonprotein Nitrogen, Mg. per 100 Cc.	Plasma Chloride, Mg. per 100 Cc.	Intravenous Treatment		Total NaCl, Gm.
			Salt Solution	Dextrose Solution	
Jan. 6	161	340	150 cc. 10% solution intravenously	500 cc. 10% solution in saline	15.5
7	198	467	35 cc. 20% solution int.	1,000 cc. 10% solution in saline	8.8
8	...	...	50 cc. 20% solution int.	1,000 cc. 10% solution	11.8
9	173	484	.....	1,000 cc. 10% solution	0.9
10	168	429	.....	1,000 cc. 10% solution	0.9
11	128	554	.....	1,000 cc. 10% solution	0.9
13	93	515			
15	94	455			
17	75	512			
20	66	512			
25	56				
29	40	550			

Accordingly a solution of 60 cc. of 10 per cent sodium chloride solution was prepared and given intravenously. Within two hours, 200 cc. of urine was obtained and the next day the small calculus was passed. The patient made an uneventful recovery, although the temperature continued elevated for the next ten days, which seemed to be due to a mild infection of the urinary tract. In July 1936 he was in excellent condition and has been seen at intervals regularly since.

CASE 2.—*Pneumonia, excessive sweating and anuria.* A business man, aged 59, entered the Deaconess Hospital Jan. 6, 1936,

blood after administration of the drug but a marked increase in those prepared from rabbit's blood under the same conditions, certain irregularities and difficulty experienced with the method would make it unwise to report at present the results obtained. All the figures for blood concentrations in this paper represent free sulfonamide.

EXPERIMENTS ON DOGS

A number of blood and urine determinations have been performed on dogs after administration of the

Chart 1.—Comparison of subcutaneous injection (1.25 per cent solution) and oral administration on blood concentration and urinary excretion of 2.04 Gm. (0.1 Gm. per kilogram) of para-aminobenzenesulfonamide given to dog D.

sulfonamide by mouth, subcutaneously or intravenously. The substance is apparently absorbed and excreted rapidly and in most instances can be almost

TABLE 1.—Excretion of p-Aminobenzenesulfonamide in Dogs After Oral Administration

P 3.....	10.2	0.10	90	
D.....	20.8	0.10	60	

completely accounted for by direct determinations on urine. No evidence of the substance being changed in passing through the dog's organism has been obtained. The unchanged material has been isolated from the urine and identified. In table 1 are presented figures for the amount of sulfonamide excreted in the urine in twenty-four and in forty-eight hours after administration of different doses by mouth. In charts 1 and 2 are given curves of the blood concentrations and urinary excretion in the same animal after administration of the same dose successively by mouth and subcutaneously or by mouth and intravenously. It is evident that subcutaneous administration of the substance does not lead to a higher blood concentration than when given by mouth; in fact, the curve of blood

concentration is somewhat lower than in the case of oral administration while the excretion of the substance is slightly more rapid. This experiment has been done three times with essentially the same result. An examination of the curves for blood concentration after intravenous injection shows that shortly after the injection only a small fraction of the substance remains in the blood stream. Only another small fraction is accounted for by the urinary excretion after the injection. Obviously, the substance passes readily from the blood into the tissues; indeed, calculations indicate that it is distributed in about 60 to 80 per cent of the body weight in different dogs. A comparison of the blood concentration and urinary excretion after oral administration with those resulting after intravenous injection

TABLE 2.—Excretion of p-Aminobenzenesulfonamide in Rabbits

Rabbit No.	Dose, Gm. per Kg.	Total Excretion in Urine in per Cent of Amount Given In			
		24 Hours		48 Hours	
		Free	Total	Free	Total
R 12.....	0.1	8	65	8	73
R 13.....	0.1	9	76	9	78

R 4.....	1.0	32	67	43	93

suggests nearly complete absorption from the intestinal tract within three to five hours. The rapidity of absorption was checked by actual determination of the amount of drug remaining in the intestinal tract some hours after oral administration.

Three dogs, weighing from 10 to 13 Kg., were given 0.1 Gm. per kilogram of para-aminobenzenesulfonamide in gelatin capsules by mouth. Exactly four hours later the animals were killed and the stomach and intestinal tract dissected out and

Chart 2.—Comparison of intravenous injection (1.25 per cent solution) and oral administration on blood concentration and urinary excretion of 1.10 Gm. (0.1 Gm. per kilogram) of para-aminobenzenesulfonamide given to dog P 3.

washed through with several liters of warm distilled water. These washings were measured and analyzed for sulfonamide. The analyses showed that 99.4, 99.2 and 77.5 per cent of the dose had disappeared (been absorbed) from the intestinal tract. The dog having the smallest absorption was heavily infested with worms.

EXPERIMENTS ON RABBITS

The amount of this substance excreted in the urine of rabbits after administration by mouth is found to be considerably less than in the case of dogs (table 2). If,

however, suggests that the loss of electrolytes had a direct effect on kidney function.

Loss of sodium and chloride by sweating or vomiting probably will not cause anuria unless the kidneys also are damaged. Heller and Smirk<sup>3</sup> demonstrated in rats a water diuresis in the presence of depleted body fluid. Darrow and Yannet<sup>4</sup> have shown a similar phenomenon in the dog. However, in neither instance was so great a reduction in the plasma chloride obtained as was noted in the 6-year old boy described by Root and Henson.<sup>1</sup> In this boy, with no demonstrable renal lesion, a plasma chloride value of 270 mg. occurred. The use of physiologic solution of sodium chloride as well as dextrose failed to produce diuresis, whereas 10 per cent saline solution caused immediate diuresis. It seems clear that cases do occur in which the use of hypertonic saline solution succeeds where physiologic solution of sodium chloride fails.

It would be desirable to estimate the chloride deficit in the body fluids in such cases. It seems that a quantitative relationship may exist between the degree of depletion of chloride and the amount of salt solution required to bring about diuresis. Thus in the 6 year old boy both physiologic solution of sodium chloride and dextrose solution had been given subcutaneously in large amounts without producing urination; when, however, 60 cc. of 10 per cent salt solution was given intravenously, recovery was complete. In this case, a rough calculation of the chloride deficit was based on the boy's weight, the estimated volume of extracellular fluid and the diminution of chloride content in the plasma.

For this purpose data should also be available for (1) changes in body weight during treatment, (2) serum protein estimations, and (3) the salt solution intake. Laviertes, Bourdillon and Klinghoffer<sup>5</sup> estimated the volume of extracellular fluid, using the method of intravenous injections of sucrose, sodium sulfate and sodium thiocyanate. They found in normal subjects that it makes up about 20 per cent of body weight. However, in subjects with advanced renal insufficiency the volume was extremely high, making up from 30 to 43 per cent of the weight. These values probably indicated "an extreme degree of wastage with replacement by interstitial fluid."

In case 2 the low hematocrit reading (table 3) for cell volume suggests that the volume of extracellular

did serve, however, to set an upper limit of the requirement, and despite acknowledged inaccuracies in such calculations a figure is obtained which gives the clinician some idea as to how much salt may be necessary for results.

#### CONCLUSIONS

1. Anuria may develop in patients who have only one kidney, with infection of mild degree, especially if a loss of base and chloride occurs as a result of vomiting or sweating or diarrhea.

2. The intravenous administration of salt solution in sufficient quantity may give relief even after ninety-six hours of anuria.

3. Hypertonic salt solution may be necessary. The use of solutions more concentrated than 10 per cent may cause a chill and is contraindicated.

4. The administration of salt in the form of liquid, such as broth, or as salt tablets, is to be borne in mind in cases in which water and chloride are being lost during excessive sweating, diarrhea or vomiting.

81 Bay State Road.

### ARTHROPATHIA PSORIATICA

#### REPORT OF CASE AND DISCUSSION OF THE PATHOGENESIS, DIAGNOSIS AND TREATMENT

HAROLD JEGHERS, M.D.

BOSTON

AND

LEON J. ROBINSON, M.D.

PALMER, MASS.

In 1933 the American Association for the Control of Rheumatism,<sup>1</sup> in reviewing the recent literature on the subject of rheumatism and arthritis, said "Psoriatic arthritis has been neglected in the English and American literature." Again in 1934 this committee<sup>2</sup> made a similar statement. Because of the paucity of recorded data on this subject, it is our purpose to report a case of psoriatic arthritis and to review briefly the pertinent literature.

#### REPORT OF CASE

*History.*—A white man, aged 54, native born, a janitor, entered the Fifth Medical Service of the Boston City Hospital July 16, 1935, with the chief complaint of "skin trouble" and "painful joints."

The patient reported that he had always enjoyed good health. There was no history of gonorrhea and syphilis. Psoriasis had been present for eighteen years. Lesions were constantly present about his elbows and knees. During the winter months the lesions would spread to involve his arms, legs and lower part of the back, followed in April or May by a recession to the quiescent state. There had never been any joint symptoms. This cycle had repeated itself year after year with great regularity. During this time no other change had occurred in the character of the psoriasiform lesions. The family and social history were irrelevant.

*Present Illness.*—From December 1934 to February 1935 the skin lesions had undergone the usual winter change. In March 1935 the patient noticed that the skin lesions, rather than receding as they had always done before, began to spread and in a

TABLE 4.—Calculation of Chloride Deficit

Body weight (148 pounds) × 25 per cent = 37 pounds or 16.8 Kg. of fluid	
Normal plasma chloride (lower limit).....	560 mg. per 100 cc.
Observed plasma chloride.....	340 mg.
Deficit plasma chloride.....	220 mg. per 100 cc.
16.8 Kg. of extracellular fluid would have a deficit of $16.8 \times 220 \times 10 =$	
36.9 Gm.	

fluid might be relatively increased, as in cases presenting advanced renal failure. If, however, one assumes that extracellular fluid forms 25 per cent of body weight and that the chloride of the plasma is of the same concentration as the chloride in the other body fluids, one may make the calculations given in table 4.

Actually no such amount was needed to produce diuresis. In case 2, anuria ceased after the administration of 24.3 Gm. of sodium chloride. The calculation

## PRESENCE IN SPINAL FLUID

Preliminary determinations indicate that the sulfonamide is present in plasma in slightly (about 10 per cent) higher concentration than in whole blood. Experiments on anesthetized dogs show that it is present in saliva and pancreatic juice in slightly lower concentration than in blood: it is also present in bile, but so far quantitative determinations of the amount

present have not been successfully accomplished. Experiments show that it readily enters the cerebrospinal fluid and is there present in a slightly lower concentration than in the blood.

The passage of the sulfonamide into the spinal fluid has been investigated on account of the experimental results indicating its value in meningococcal infections.<sup>6</sup> Chart 4 gives data on concentrations in the blood and cerebrospinal fluid obtained by cisternal puncture of a dog after administration of the substance by mouth.

In three patients after administration of the drug we have had the opportunity of examining spinal fluid (obtained by lumbar puncture); in one, in whom no blood sample was obtained, the spinal fluid had 4.6 mg. per hundred cubic centimeters after the patient had received 0.06 Gm. per kilogram daily of sulfonamide for seven days. This is probably only slightly lower than the concentration expected in the blood from the dosage given. The second patient received 0.09 Gm. per kilogram in one dose, and spinal fluid four hours later had a concentration of 2 mg. per hundred cubic centimeters, blood taken at the same time containing 5

mg. and one hour earlier 4 mg. In the third instance, 0.057 Gm. per kilogram was given in one dose, and spinal fluid at five hours contained 3 mg. per hundred cubic centimeters, blood at four hours contained 6.5 mg. and one hour after lumbar puncture 5 mg. One would expect a greater lag in the lumbar fluid than in the cisternal.

It may incidentally be mentioned that in one instance in an empyema fluid, from a patient with hemolytic streptococcal pneumonia treated with 2.4 Gm. of sulfonamide daily, we found 3.5 mg. per hundred cubic centimeters of the drug. Fluid from a pleural effusion of another patient, who was receiving from 0.10 to 0.12 Gm. per kilogram of sulfonamide daily, contained 11 mg. per hundred cubic centimeters.

## COMMENT

The determination of the concentration of para-aminobenzenesulfonamide present in blood in patients undergoing treatment with the drug is important from many aspects. Concentrations between 1:5,000 and 1:10,000 can be attained and maintained in blood. Further studies on streptococci in vitro such as those already reported,<sup>7</sup> as well as in vivo experiments in infected animals, will be necessary before the mechanism of the action of the drug is finally elucidated. For such studies a knowledge of the concentrations that are found in patients undergoing treatment is essential.

Experiments on mice infected with  $\beta$ -hemolytic streptococci demonstrate that the maximum curative effect of para-aminobenzenesulfonamide is exerted by maintaining a high concentration of this substance in blood and tissues for several days.<sup>8</sup> We can safely assume that the concentration of the drug in the tissues is dependent on the concentration in the blood. From

After observation for a short period, the patient was discharged Nov. 16, 1935, again able to be active (fig. 3). Before discharge the secondary anemia, sedimentation rate and total protein returned to normal.

This case was typical of the cases described in the literature. Dermatologists who saw the patient agreed with the diagnosis of psoriasis. The skin lesions on the body were typical. A few lesions about the hands and feet suggested pustular psoriasis. However, the skin lesions may have changed during the few months before we saw the patient.

Although not responding to measures directed primarily to the joints, the arthritis healed promptly after the skin lesions disappeared. The carious teeth evidently played no important rôle, since they were not touched until the joints subsided.

#### COMMENT

Arthropathica psoriatica (psoriasis arthropathica) as a distinct clinical entity has been of particular interest since Alibert<sup>5</sup> in 1822 recognized the occurrence of joint pains in psoriasis. Bazin<sup>6</sup> in 1860 distinguished between psoriasis with arthritis and without arthritis and applied the term psoriasis arthritica to the former variety. Adrian<sup>7</sup> reviewed the subject in 1903 and did much to establish this syndrome as a clinical entity. Since then several contributions have appeared yearly, mainly in the foreign literature. A fairly intensive search of the available literature disclosed but a few reports from this country.

Since cases are so rarely reported, the syndrome is probably an unfamiliar one. The only statement as to the incidence in this country is made by O'Leary,<sup>8</sup> who saw eight instances of this syndrome among 1,400 cases of psoriasis. However, only one of these was reported in detail.<sup>9</sup> The comparative rarity of this combination of two such common diseases as arthritis and psoriasis has been commented on by O'Leary,<sup>8</sup> who further remarked that "this syndrome was the foremost exception to the dictum of Hebra: 'Psoriasis is a disease of healthy people.'"

Probably this syndrome has failed to receive attention in this country mainly because of its dual manifestations, causing interest in it to be divided between two distinct specialties.

Even a brief survey of case history reports from dermatologic papers dealing with psoriasis substantiates the validity of this statement. Several have excellent descriptions of the arthritic manifestations of arthropathica psoriatica, but only rarely can this syndrome be judged to be present from the title of the paper.

For example, Ebert<sup>10</sup> observed a woman of 31 who exhibited a polyarthritis which became manifest and subsided simultaneously with the appearance and subsidence of a pustular exacerbation of a long standing psoriasiform eruption. Of particular interest was Graham's<sup>11</sup> patient, a man aged 53, who over a period of five years had three exacerbations of generalized pustular psoriasis, each attack lasting several months and accompanied by pain and swelling of the joints of the feet, ankles and wrists. The arthritic manifestations disappeared when the pustular lesions cleared. The common scaly type of psoriasis persisted between the pustular exacerbations. Similar instances of arthri-

tis were noted in cases of psoriasis reported by Barker,<sup>12</sup> DeWolf<sup>13</sup> and Rostenberg.<sup>14</sup>

Most of these dermatologic reports were instances of pustular psoriasis superimposed on the common scaly form of psoriasis. This means little, since the usual forms of psoriasis are rarely the subject of case reports at present. However, arthritis was not present in every case of pustular psoriasis found reported.

While the descriptions of the skin lesions in these articles are excellent, the data on the arthritic manifestations are too limited to be of much value to the internist.

A somewhat comparable situation exists when instances of psoriatic arthropathy are reported by internists.<sup>15</sup> Here much attention is devoted to the description of the arthritis and relatively little to the skin lesions.

Fig. 3.—Condition shortly before discharge. Skin is free from lesions and tan from the ultraviolet therapy. Diminution in the swelling of the knees, wrists and ankles is noticeable.

All this indicates that the dermatologists tend to ignore the arthritis, while the internists pay little attention to the skin lesions. What is greatly needed is a study of a series of such cases combining the observations of both the dermatologists and the internists.

#### DIAGNOSIS

The diagnosis of true arthropathica psoriatica depends mainly on the close relationship which the exacerbation and subsidence of the skin and joint manifestations bear to each other.<sup>16</sup>

The common scaly form of psoriasis was usually present for many years, during which time there was no arthritis. Joint manifestations commonly appear a

during the pains. She will not sleep during any pains with the first dose, but after receiving the second dose, i. e., a total of 9 grains (0.6 Gm.) she will frequently sleep while having a uterine contraction and awaken only when the pain is especially severe. Not all patients react as well as this. About one out of every ten patients becomes more irritable and nervous than before. She will try to get out of bed, will say that the capsules do not help her one bit, and will yell and carry on considerably during the pain. With those patients, after having had six capsules of pentobarbital, I give enough chloroform with each pain to relieve the pain completely. After the patient has had chloroform with about fifteen to twenty pains, the latter quiet down. I then stop the chloroform and do not start it again until the perineal stage, except occasionally when it may be necessary throughout the second stage. If labor lasts more than six hours after the second dose of pentobarbital, I give two more capsules; and if the pains are not strong enough, I give 5 or 10 grains of quinine along with the pentobarbital.

The patients' reactions seem to be nearly always favorable. Those who have had babies before always

say that the capsules are the most wonderful thing that could be. Occasionally a primipara will be a little disappointed because she did not get as much relief as she expected. I usually find that she has been talking to some other woman who had a baby before and had praised the capsules a little too highly. These cases, however, are rare.

There is hardly ever a trained nurse in attendance, so the husband or a neighbor woman is instructed to watch the patient so that she doesn't fall out of bed or try to get up. All normal deliveries are made in beds, and because the beds found in these homes are usually low there is not much danger if the patient should happen to fall out.

Chloroform is used in the second stage of labor with all normal deliveries. Ether is not safe, because the average farmhouse has a stove burning and one or two lamps lighted. Nitrous oxide is too cumbersome, inconvenient and expensive. The rural physician gets only \$25 for the average delivery, which includes antepartum care. After the patient has had pentobarbital she does not require very much anesthetic for the second stage of labor. Either the husband or the neighbor woman gives the chloroform, a little with each pain. If the chloroform slows up the pains too much the patient, if she is a primipara, is given 0.5 cc. of

solution of posterior pituitary when the os is fully dilated and the head is low. Then by being given a little more chloroform the patient is delivered while asleep.

With breech and forceps deliveries the patient is kept in a seminarcois with pentobarbital until ready for delivery. I find that breech and forceps babies are always in much better condition after the use of pentobarbital than after pantopon and scopolamine. It almost never takes longer than five minutes to establish respiration in the infant. All that I ever find necessary is to aspirate the mucus with a catheter and, perhaps, a little mouth to mouth artificial respiration with a little gauze over the baby's mouth. For a breech or forceps delivery in the home the patient is put crosswise on the bed or on the dining room table. Ether is always used in place of chloroform and I get the husband and two extra women to help. Before starting ether we close the drafts on the stove and set all lamps up high to avoid explosions or fires. A flashlight is used if perineal repair is needed. One woman gives the ether while the husband and the other woman each hold a leg. I have to supervise the anesthetist, who perhaps never gave an anesthetic before; at the same time I must complete the delivery.

In compiling this report I checked over the last 200 consecutive deliveries, covering a period of nearly two years, and feel that they are a fair representation of rural obstetrics. The following facts were noted in this group:

There were no maternal deaths. As a matter of fact, I have never had a maternal death in the eleven years that I have been in rural practice, with nearly a thousand deliveries.

There were four infant deaths, which, I believe, cannot be laid to the pentobarbital but probably would have taken place regardless of the choice of drug.

The cases in this series may be classified as in the accompanying table.

#### REPORTS OF INFANT DEATHS

CASE 1.—M. B., a primipara with edema and a blood pressure of 180 systolic, 110 diastolic, was given castor oil and quinine ten days previously. Labor did not start, but toxemia improved. The bag of waters ruptured spontaneously at 6 a. m. Quinine 20 grains (1.3 Gm.) was given in 5 grain (0.3 Gm.) doses in the morning; the pains started at noon. Pentobarbital 6 grains (0.4 Gm.) was given at 1 p. m. The first stage lasted three and one-half hours, the second stage one hour. There was a normal delivery. The baby weighed 7 pounds (3,175 Gm.). There was no pulsation of the cord at birth. The baby was blue; no heart beat was felt. After one hour the baby could breathe alone. Ten hours after birth the baby became cyanotic and had convulsions. Oxygen was given but the baby died fourteen hours after birth.

CASE 2.—Q. M., a secundipara, whose first pregnancy resulted in a stillbirth, was eight months pregnant. Labor started at 1:30 a. m. Pentobarbital 6 grains was given at 5 a. m. After five hours of labor a 4¾ pound (2,154 Gm.) baby was born. The baby seemed well but was found dead in its crib four hours after birth. Blood sugar was normal and the Wassermann reaction of the mother was negative.

CASE 3.—F. A., a tertipara, whose previous pregnancy had occurred thirteen years before, gave birth to a 6½ pound (2,948 Gm.) baby after labor lasting twenty-three hours in the first stage and an hour and a quarter in the second stage. Seven capsules of pentobarbital 1½ grains (0.1 Gm.) was given; also 20 grains of quinine and 1 cc. of solution of posterior pituitary were given. Apparently the baby was all right at birth but several hours later it expelled a little blood from the nose and died suddenly. The patient was delivered again normally with a live baby twelve months after this labor.

## PARA-AMINOBENZENESULFONAMIDE

ABSORPTION AND EXCRETION: METHOD OF  
DETERMINATION IN URINE AND BLOOD

E. K. MARSHALL JR., PH.D., M.D.

KENDALL EMERSON JR., M.D.

AND

W. C. CUTTING, M.D.

WITH THE TECHNICAL ASSISTANCE OF DOROTHEA BABBITT  
BALTIMORE

The increasing use of para-aminobenzenesulfonamide in the treatment of streptococcal infections has prompted us to report the results which we have obtained on the absorption and excretion of this drug. Although these results offer by no means a complete and finished study of the subject, the obvious application of certain of our observations to the therapeutic use of the drug and the simple method that has been devised for determining the substance in blood and urine would appear to justify a presentation of our preliminary results at this time.

## METHOD OF ANALYSIS

The method for analysis of blood and urine (as well as certain other body fluids) is based on diazotization of the aminobenzenesulfonamide with nitrous acid, and coupling the resulting diazo compound in acid solution with dimethyl- $\alpha$ -naphthylamine to produce a purplish red azo dye which can easily be estimated by colorimetric comparison. This reaction depends on the presence of an amino group substituted in the benzene ring and will estimate any compound to which the sulfonamide is changed in the organism and in which the amino group is intact. This color reaction is exceedingly delicate, being detectable in a solution of the sulfonamide of 1 part in 20 million parts of water.

For the determination of para-aminobenzenesulfonamide in blood and urine, the following reagents are necessary:

1. Tenth normal hydrochloric acid.
2. Sodium nitrite 0.1 per cent (freshly prepared).
3. Ethyl alcohol (95 per cent).
4. Dimethyl- $\alpha$ -naphthylamine, 1 cc. to 100 cc. of alcohol.
5. A standard solution of para-aminobenzenesulfonamide, 200 mg. per liter. From this solution standard solutions containing 1.0, 0.5 and 0.2 mg. per hundred cubic centimeters can be prepared. The standard solution appears to keep unchanged for several months if kept in the icebox.

Urine is diluted so that the diluted solution contains from 0.5 to 1.5 mg. per hundred cubic centimeters of sulfonamide.<sup>1</sup> Ten cc. of this diluted urine is measured into a small flask and 2 cc. of hydrochloric acid, 1 cc.

This investigation has been aided by a grant from the Josiah Macy Jr. Foundation.

Drs. Emerson and Cutting are Fellows in Experimental Therapeutics and Medicine.

The Winthrop-Chemical Company furnished the para-aminobenzenesulfonamide used in this investigation.

From the Department of Pharmacology and Experimental Therapeutics, Johns Hopkins University School of Medicine.

Dr. Perrin H. Long cooperated in the studies on patients. He has been conducting the treatment on these patients, and has generously aided our investigation in every way possible.

1. With the amounts of sulfonamide administered to patients we have found dilutions of 1:50, 1:100 or 1:200 to be satisfactory. We have not used concentrations greater than a 1:50 dilution, as in strongly buffered urine the amount of hydrochloric acid used may not be sufficient and substances of the urine may interfere with color development. Normal urines and a dozen urines obtained from patients with various diseases gave negative tests with the reagents in 1:10 and 1:50 dilutions. Dog or rabbit urine may give a faintly positive test in a 1:50 dilution but the amount of normal urinary constituent giving the reaction can be neglected here. It is essential to use all glass cups in the colorimetric comparison, as the ordinary cup with detachable glass bottom may give inconsistent and erroneous results. On one occasion the use of flasks in which chloride determinations had been carried out resulted in inconsistent results. It appears that mere traces of metallic salts may cause difficulty in accurate colorimetric comparison.

of sodium nitrite, 5 cc. of alcohol and 1 cc. of dimethyl- $\alpha$ -naphthylamine are successively added. The flask is shaken after the addition of each reagent. Ten cc. of an appropriate standard is similarly treated. After a few minutes standing, the solutions are compared in the colorimeter. Just after the dimethyl- $\alpha$ -naphthylamine has been added the solutions may not match exactly, while after too long standing an orange tint occurs in the diluted urine which gives low readings. Readings are usually taken from five to ten minutes after the addition of the reagents. The color developed in standard solutions in pure water appears to remain unchanged for several hours.

For blood, the following procedure is used: One volume of blood is run slowly with shaking into 9 volumes of alcohol, and the flask is stoppered and allowed to stand ten minutes or longer. The mixture is now filtered and 10 cc. of the filtrate measured into a small flask. Five cc. of water, 2 cc. of hydrochloric acid, 1 cc. of sodium nitrite and 1 cc. of dimethyl- $\alpha$ -naphthylamine are successively added. The colored solution is slightly turbid but after standing five minutes can be filtered and the clear filtrate used for colorimetric comparison. An appropriate standard is prepared at the same time by adding 1 cc. of a standard solution of the sulfonamide to 9 cc. of alcohol and treating this solution as described for the blood filtrate. Color comparison is best made about fifteen or twenty minutes after the reagents have been added. Since only 92 per cent of the sulfonamide is recovered from blood by this procedure, the final result is divided by 0.92 to obtain the correct concentration in blood. Subsequently we have found that if the dimethyl- $\alpha$ -naphthylamine is added about three minutes after the sodium nitrite a more intense color is obtained and the recovery is practically 100 per cent.

The accuracy of this method has been checked on pure solutions of sulfonamide, on normal urine and on urines containing sulfonamide to which more sulfonamide has been added, and on normal dog and human blood after the addition of sulfonamide. Duplicate determinations usually check within 2 or 3 per cent.

In the rabbit and the human subject, this compound is partly excreted in the urine as a conjugated compound which does not give the color reaction directly, owing to a blocking of the amino group. The para-aminobenzenesulfonamide can be obtained from this compound by hydrolysis with dilute hydrochloric acid. To determine this conjugated compound in urine, we have heated equal volumes (usually 1 cc.) of urine and normal hydrochloric acid in a test tube (25 by 200 mm.) covered by a small beaker in boiling water for thirty minutes. The solution is cooled and, after the addition of 1 drop of 0.1 per cent phenolphthalein, neutralized with 2 normal sodium hydroxide. After dilution to appropriate volume, the determination is performed as described for urine. Samples of urine heated with 1 or 3 normal hydrochloric acid for thirty, forty-five and sixty minutes yield identical values for the conjugated compound, and subjecting a solution of sulfonamide of known strength to acid hydrolysis results in no loss as determined by the colorimetric method. This would indicate that the method is accurate for determining the hydrolyzable material in urine.

Blood filtrates have been hydrolyzed by adding to 10 cc. of the filtrate, 2 cc. of 0.5 normal hydrochloric acid, evaporating the alcohol by immersing in boiling water and heating for thirty minutes. While the use of this method gives no increase in filtrates from dog's

### EFFICIENCY OF FLAVORING AGENTS IN DISGUISSING THE BITTER TASTE OF ALKALOIDS

The group of tests for determining the efficiency of flavoring agents in disguising the bitter taste of alkaloids was made by adding 0.1 per cent quinine bisulfate to the various flavoring agents. This produced a bitter taste sufficiently intense so that it was not completely masked by any of the flavoring agents and corresponded to a greater degree of bitterness than is produced by a

solution of codeine sulfate containing 30 mg. (one-half grain) to the teaspoonful. The results obtained over the four year period are summarized in table 1.

Particularly worthy of note are the very satisfactory results obtained with the new Syrup of Raspberry (Syrupus Rubi Idaei) N. F. VI, which should make a most useful flavoring agent for disguising the taste of bitter drugs.

Aromatic Syrup of Eriodictyon (Syrupus Eriodictyi Aromaticus), although not well liked as a flavoring agent (35 per cent), is highly effective in disguising the bitter taste (73 per cent) and, being moderately effective also in covering the saline taste (54 per cent), is well adapted to disguising mixtures of codeine sulfate and ammonium chloride.

It is also interesting to note that the efficiency of the new Syrup of Prepared Cacao (which differs from the old Syrup of Cocoa, N. F. V, in containing oil of theobroma, starch and twenty-five times more tincture of vanilla), while moderately effective in disguising the bitter taste (67 per cent), appears to be decidedly inferior to the older preparation, which over three years obtained an average score of 81 per cent.

The remainder of the flavoring agents studied for their ability to disguise the bitter taste appear to be decidedly inferior to the syrups of raspberry, eriodictyon and cacao.

### EFFICIENCY OF FLAVORING AGENTS IN DISGUISSING THE SALINE TASTE

In the group of tests for determining the efficiency of flavoring agents in disguising the saline taste, ammonium chloride was added to the various flavoring agents in a concentration of 8 per cent. This gives a preparation containing 0.4 Gm. (6 grains) of ammonium chloride per teaspoonful. The results obtained in this series of tests are shown in table 2.

Here it will be observed that most of those flavoring agents which were found to be highly effective in disguising the bitter taste are relatively ineffective in masking the taste of salty drugs.

Those flavoring agents which have proved to be most effective in disguising the salty and burning taste of ammonium chloride are the syrups of cinnamon, orange, sarsaparilla, eriodictyon and citric acid.

As a further test of the efficiency of the four flavoring agents found most effective in disguising the saline taste, a comparison has been made of their efficiency in disguising sodium bromide with that of the official Elixir of Sodium Bromide, N. F., in which Aromatic Elixir is used as the vehicle. All preparations contained the same amount of sodium bromide as the official elixir; namely 17.5 per cent.

The results obtained in these tests in comparison with those obtained in disguising 8 per cent ammonium chloride are shown in table 3.

It is of interest to note from these results that the flavoring agents maintain the same relative positions in point of efficiency in disguising both ammonium chloride and sodium bromide and that all these flavoring agents are from two to three times more effective in disguising the taste of sodium bromide than is the official elixir.

### EFFICIENCY OF FLAVORING AGENTS IN DISGUISSING THE TASTE OF TINCTURE OF DIGITALIS

In making tests to determine the efficiency of flavoring agents in disguising the taste of tincture of digitalis, tincture of digitalis was added to the various flavoring agents in a concentration of 10 per cent. This makes a preparation containing approximately 0.5 cc. of tincture of digitalis per teaspoonful. The results obtained in this group of tests are shown in table 2.

The syrups of raspberry, cacao and eriodictyon appear to be the most effective agents in disguising the disagreeable taste of tincture of digitalis. Less effective are the syrups of cherry, citric acid, orange and wild cherry.

### ALL-ROUND EFFICIENCY OF FLAVORING AGENTS

If equal weight is given to each of the four characteristics that have been studied, an average figure may be obtained which is a measure of the all-around efficiency for routine use of the various flavoring agents. The average values so obtained are shown in table 4.

It appears from this table that the syrups of prepared cacao, raspberry and eriodictyon are the "all-purpose" flavoring agents of choice, with the syrups of

however, the rabbit's urine is heated with dilute hydrochloric acid, a very great increase in the amount of sulfonamide is noted. Evidently the rabbit excretes the substance partly in the form of a conjugated derivative in which the amino group is blocked. This conjugated compound has been isolated from the urine of rabbits receiving 1 Gm. per kilogram of para-aminobenzenesulfonamide and identified as para-acetylaminobenzenesulfonamide.<sup>2</sup> Dr. Perrin H. Long tested its effect on  $\beta$ -hemolytic streptococcal infections in mice

Chart 3.—Blood concentration curves of five patients following oral administration of a single dose of para-aminobenzenesulfonamide. A, 4.8 Gm. (0.09 Gm. per kilogram); B, 3 Gm. (0.05 Gm. per kilogram); C, 3.6 Gm. (0.05 Gm. per kilogram); D, 4.8 Gm. (0.066 Gm. per kilogram); E, 4.5 Gm. (0.06 Gm. per kilogram).

and found it almost inactive. Buttle, Gray and Stephenson<sup>3</sup> state that the acetyl derivative is much less active than the sulfonamide itself, while Fournau, Tréfouël, Nitti and Bovet<sup>4</sup> simply state that this derivative is active. Table 2 gives the excretion of free and total (free and easily hydrolyzable conjugated compound) in experiments on rabbits with a moderate and very large dose by mouth.

#### PATIENTS TREATED WITH SULFONAMIDE

The human subject excretes the drug partly unchanged and partly in conjugated form.<sup>5</sup> This conjugated form is mainly, if not entirely, para-acetylaminobenzenesulfonamide, which has been isolated from the urine of patients receiving the para-aminobenzenesulfonamide. In chart 3 are given blood concentration curves on individuals after administration of a single large dose by mouth. The five blood concentration curves given in chart 3 appear to indicate that differences in the rate of absorption of the drug occur in human individuals. Curves B, C and D resemble closely the curves obtained in experiments on normal dogs; curve A indicates quite slow absorption, while curve E suggests extremely rapid passage of the substance into the body from the intestinal tract. At the end of twenty-four hours patients D and E show appreciable amounts of the substance still present in the body, while B and C show less than 1 mg. per hundred cubic centimeters in the blood. Patient D had definite signs of kidney impairment, and E had

just recovered from a pneumonia. It is possible that para-aminobenzenesulfonamide may be a more delicate test of kidney function than substances now in use.

In certain patients undergoing prolonged treatment with para-aminobenzenesulfonamide administered in divided doses throughout the day, we have followed the urinary excretion and blood level for several days. Table 3 gives the essential data. The bloods were taken one-half hour before administration of a dose.

An examination of this table shows that in administering a given daily amount of the drug in divided doses it takes from two to three days to establish equilibrium between the amount ingested and the amount excreted; after equilibrium is established it takes about the same time (from two to three days) to free the organism of the drug. When the body is in equilibrium in respect to the drug, one can frequently account for almost 100 per cent of the daily dose ingested by the total excretion of the sulfonamide in free and conjugated form. It is possible that under certain conditions a small amount is excreted in the urine in some other form or eliminated through some other channel than the kidneys. The blood concentration can be maintained fairly constant for a long time. In the first four patients in table 3 the daily excretion amounts to 0.07 to 0.12 Gm. per kilogram. To excrete this amount, blood concentrations of from 11 to 16 mg. per hundred cubic centimeters are required.

Since the sulfonamide is so rapidly excreted by the kidney, one might expect with impaired renal function that smaller doses would suffice to raise the blood concentration to any given level and that after stopping administration of the drug a much longer time would be required to clear the body of the substance. This has indeed been found to be the case in two instances that we have studied (table 4). In the first patient a blood concentration of 11 mg. per hundred cubic centimeters resulted in the excretion of only about 0.016 Gm. per

Chart 4.—Comparison of concentrations in blood and cisternal fluid in dog P 6 after administration of 0.1 Gm. per kilogram of para-aminobenzenesulfonamide by mouth.

kilogram; five days after the drug was discontinued, a large amount was still present in the body as shown by the blood level of 5.1 mg. per hundred cubic centimeters, and even twelve days after withdrawal the sulfonamide was still being excreted in small amounts, mainly in a conjugated form. The less complete data on the second patient also indicate the effect of impaired renal function. Of course, the few cases that we have studied justify only tentative conclusions with regard to the effect of impaired renal function in the excretion of the drug. Different types of renal insufficiency will have to be investigated before final conclusions are drawn.

5. As this paper was being submitted for publication, we received the January 23 issue of the *Lancet* containing an article by A. T. Fuller entitled "Is *p*-Aminobenzenesulfonamide an Active Agent in Prontosil Therapy?" *W* human beings and in mice para-aminobenzenesulfonamide is excreted in the urine in both free and conjugated forms.

ning of our studies we used an antigen forwarded to us from the Cleveland City Hospital through the courtesy of Dr. W. H. Connor. Later the antigens were prepared at the Hooper Foundation. From one of our patients we were able to collect sufficient pus for the preparation of a satisfactory antigen, which we have used consistently since April 1936. Other antigens have been prepared from later cases. In the preparation of the antigen we followed closely the directions given by Frei in 1925. The pus was secured by aspiration from unbroken fluctuant buboes. If it proved to be bacteriologically sterile, it was diluted 1:6 in sterile saline solution and the virus killed by heating the diluted pus to 60 C. for two hours on one day and for one hour on the following day. No chemical preservatives were added to the antigen used for diagnostic purposes. Such additions may cause misleading nonspecific reactions in some individuals. Antigens so prepared provide excellent mediums for the multiplication of bacteria; consequently the greatest care must be exercised in its use to prevent contamination. Whenever the sterility of an antigen previously used is not definitely known, it should be recultured before further use. Antigen containing bacteria should not be resterilized but must be discarded. Reactions simulating positive Frei tests may be obtained in normal individuals with contaminated antigen. We recommend the use of small bottles with rubber caps containing about 0.2 cc. of antigen, 0.1 cc. to be used on the suspected patient and 0.1 cc. on a control. If only a part of the contents of such an ampule is used, the rest should be discarded.

Any antigen must be tested for its specificity and potency in proved cases and in a sufficient number of controls. Whether or not small amounts of blood contained in the pus removed will interfere with the specificity of the antigen will become evident from these tests. If properly kept in an icebox, antigens remain effective for a period of from one to two years. It is necessary, of course, to check the specificity and sterility of the antigen from time to time. When an unknown antigen is used it is necessary to run a control in a patient not suspected of the disease.

*Frei Test.*—In performing the test, 0.1 cc. of the antigen is injected intracutaneously, preferably on the flexor surface of the forearm. The positive reaction is a delayed one. A red papule appears about twenty-four hours after injection and increases in size up to forty-eight or even seventy-two hours. We usually do the final reading after forty-eight hours, noting the diameter in millimeters of the red papule and of the surrounding erythematous halo, if present. In the series described in this article we have considered the reaction positive if the diameter of the papule was 6 mm. or more. Reactions smaller than this, or different in character and yet suggestive, have been designated as questionable. As in other tests, especially the Wassermann reaction, questionable reactions must be checked and interpreted on the basis of available clinical and historical data. No satisfactory standardization of the antigen has yet been devised. Quantitative (amount of virus) and qualitative ("types" or "strains") differences probably play an important rôle, to be investigated in the future. Differences in the intensity of the reaction to several different antigens on the same patient are not uncommon. In our experience, however, cases proved positive with one antigen have practically always been positive with other reliable antigens.

The specificity of the Frei test is well established, as is evident in this report. Positive reactions should, if possible, be confirmed by the use of other known antigens. We have followed this routine when circumstances permitted.

The positive test gives evidence of an acquired specific allergy, which in most instances continues throughout the life of the patient. Consequently a positive test does not necessarily indicate the presence of a recently acquired active infection. Old completely healed infections may eventually give positive reactions. Negative reactions may be seen in cases in which the specific allergy has not yet developed or in those in which the reaction is suppressed by factors known to lower the allergy in other infections. It is stated that syphilis may prevent a positive reaction to the Frei antigen.

It is known that the clinical manifestations of lymphogranuloma inguinale may be transient, or so insignificant that they pass unnoticed. For this reason we feel justified in assuming a previous infection in persons giving a positive test, regardless of the absence of a clinical history of the disease. The Frei test, properly performed and controlled, is much more reliable than the observation or memory of the individual involved.

Antigen prepared from pus secured from a clinical suspect may be assumed to contain the virus of lymphogranuloma inguinale, provided it gives positive reactions in known positive cases. Conversely, negative reactions with the same antigen indicate the absence of the virus. Positive reactions with such an antigen in the patient from whom it was secured are of no diagnostic value, since the same reaction may be obtained in the presence of other infections, such as chancroid, for example. The demonstration in proved cases of the antigenicity of pus or ground material from a diseased gland of a suspected individual is of paramount importance if the Frei test proves negative. A good example of this was described in England by Stannus. Apparently a syphilitic infection prevented development of a specific allergy to the Frei antigen in his patient, yet the virus could be demonstrated in the pus obtained from an inguinal gland by its power to elicit positive Frei tests in proved cases and by the successful transmission of the virus to susceptible animals by intracerebral inoculation.

We have attempted to transmit the virus from some of our cases to groups of mice, and, in one instance, to a monkey. We were not able to obtain enough passages of the virus in our cases to use this as diagnostic evidence of the disease. We believe that the strain of mice used was insufficiently susceptible to the virus of lymphogranuloma inguinale to make these attempts of clinical importance. Mice were successfully infected at the Hooper Foundation from two known cases of lymphogranuloma inguinale before these studies were initiated.

#### CASES PRESENTING ONLY INGUINAL MANIFESTATIONS

During the past four years, twenty-three patients have been observed in the San Francisco Hospital in whom it was possible to make a positive diagnosis of inguinal adenitis due to the virus of lymphogranuloma inguinale. There were twenty-one males and two females in this group.

Aspirated material from the swollen glands in twenty-one of these patients showed an absence of

bone and fat, which probably do not absorb much of the substance), (4) the efficiency of the kidneys in excreting the drug, and (5) the amount of the drug present in the body in conjugated form (inactive). From our limited data it would appear that 1 and 4 are the most important of these factors for the human subject. When the drug is given in small doses every few hours for several days, the efficiency of the renal function of the individual will be the important factor determining the concentration in the blood.

On dogs our blood concentration and excretion studies indicate nearly complete absorption in about four hours. Direct determination of the absorption in four hours shows that it is complete or nearly so. Since the blood concentration curves in the human subject after a single dose by mouth usually resemble those obtained with dogs, we can conclude that absorption is in most instances complete or nearly complete in man in about four hours. For this reason, if the daily dose is to be divided in order to attempt to maintain a nearly uniform concentration in blood and tissues, a four hour interval between doses would appear to be indicated. If it is desired to reach quickly a high blood concentration and maintain it, a large single dose (e. g., 0.05 Gm. per kilogram) could be given and followed after six to eight hours by the usual dose every four hours. From our studies of absorption of the drug when given by subcutaneous injection as compared to oral administration, no advantage is gained by injection in attaining the desired concentration in the blood. When possible, oral administration would appear to be indicated.

The finding of the drug in spinal fluid obtained by cisternal or lumbar puncture in only slightly lower concentration than in blood within a few hours of administration by mouth suggests that the drug may be given by mouth when its presence in the cerebrospinal fluid is desired.

#### SUMMARY

1. A method has been devised for determining paraminobenzenesulfonamide in blood and urine. A conjugated form excreted in urine can be determined after hydrolysis with dilute hydrochloric acid.

2. In the dog, the substance appears to be excreted unchanged in the urine, while in the rabbit large amounts are excreted in a conjugated form. In man, the substance is excreted in both the free and the conjugated forms.

3. Absorption from the gastro-intestinal tract is rapid, being usually complete or nearly complete in about four hours.

4. In dogs, the concentration in the blood does not mount more quickly or attain a higher level with subcutaneous administration than with oral.

5. In patients, when large amounts are administered daily in divided doses nearly 100 per cent may be recovered from the urine when equilibrium between intake and output is established. It takes from two to three days to establish this equilibrium and the same time to free the body of the drug after it is discontinued.

6. In patients with impaired renal function, the sulfonamide appears to be excreted more slowly. Until more data are available it should be given with care in all cases of renal insufficiency.

7. After oral administration, the sulfonamide is found to be present in the cerebrospinal fluid in a somewhat lower concentration than in blood.

## PENTOBARBITAL-SODIUM ANALGESIA IN OBSTETRICS IN THE HOME

REPORT ON 200 CASES

WILMER C. EDWARDS, M.D.

RICHLAND CENTER, WIS.

When I first started the practice of obstetrics after leaving the Evanston Hospital about eleven years ago, pantopon (a mixture of opium and alkaloids) and scopolamine were being used for analgesia, as was taught when I interned at that time. It was the method of choice for about eight years, or until about three years ago, when I changed to pentobarbital, which I have been using ever since. When using pantopon and scopolamine I made a lot of friends among new mothers who previously had not had any relief of pain during labor; but at the same time I had a number of babies that were slow to breathe and quite cyanotic. It was always with a great deal of anxiety that I gave the second hypodermic of scopolamine and pantopon, for often I would have to work a half hour or more to get the baby to breathe properly.

There is an entirely different type of practice in the country from that in the city. Richland Center, Wis., is a strictly rural community. It has only 4,000 inhabitants and the nearest physicians are about 15 miles away, the nearest cities about 70 miles, so I frequently go from 20 to 30 miles on a call. Although there is available a splendid hospital of fifty beds, the average obstetric patient cannot afford the \$45 necessary for ten days at the hospital and prefers to stay at home. Another thing that one has had to contend with since the depression is the scarcity of telephones, about one farmer out of ten having a telephone. The country physician does not want his obstetric patients to call him too soon, and when he goes he wants to get through as soon as is absolutely safe for the mother and baby. My experience has been that scopolamine and pantopon will slow up labor considerably, while pentobarbital does not seem to affect the length of labor very noticeably.

I have my patients come to the office once every three weeks for urine examination and a check on weight and blood pressure, and they are instructed to notify me as soon as labor starts. This is so that I will be available immediately, if needed. Then, if the patient is a multipara she is to call again when the pains occur every five to seven minutes and are regular; and if she is a primipara she is to let me know when the pains are less than every five minutes and are hurting considerably. Those who live far away are instructed to call much earlier than those living near by. At the second call I go to the patient and give her four capsules of pentobarbital (6 grains, or 0.4 Gm.). If she is a multipara and is progressing rapidly, I start chloroform as soon as the os is fully dilated. If the os is not fully dilated in forty-five minutes I give two more  $1\frac{1}{2}$  grain (0.1 Gm.) capsules of pentobarbital if the pains are still acute. Primiparas are given two more capsules in about one to two hours, depending on the severity of the pains. With most of the cases this is the total amount of pentobarbital given.

In from fifteen to thirty minutes after the first dose of pentobarbital the patient begins to get relief, which seems to reach its maximum effect in less than an hour. The first thing that one notices is that the patient drops off to sleep between pains and will cooperate better

of Dr. E. A. Levin) was positive. The antigen prepared from this patient gave a positive test in a case of chancroid with typical ulcers from which Ducrey's bacilli had been demonstrated but negative reactions in proved cases of lymphogranuloma inguinale. Subsequently we have used this antigen for demonstrating the specific allergy produced by the causative agent of chancroid as described by Cole and Levin<sup>8</sup> and have found it highly satisfactory in the differential diagnosis of lymphogranuloma inguinale and chancroid.

Total	295	26 (8.9%)	262 (88.8%)	7 (2.4%)

Similar to the positive skin reaction in lymphogranuloma inguinale, a positive test to a chancroid antigen gives evidence of a specific allergy produced by a previous infection with the bacillus of Ducrey.

Table 1 includes all the cases studied with both the Frei test and the chancroid antigen since April 1936. In many of these patients the venereal infection occurred from ten to thirty years ago.

#### FREI TESTS IN A SURVEY OF 700 ADULTS

The results of a general survey of 405 adult patients (281 males and 124 females) in the general wards of the San Francisco Hospital are shown in table 2.

8. Cole, H. N., and Levin, E. A.: Intradermal Reaction for Chancroids with Chancroidal Bubo Pus, J. A. M. A. 105:2040 (Dec. 21) 1935.

Patients investigated because of clinical evidence of lymphogranuloma inguinale were not included in this table. Many of the patients in this series in whom positive or questionable reactions were obtained were found on careful questioning to have had one or another clinical manifestation suggestive of the disease at some time during their adult lives. Unfortunately, some of the patients tested were dismissed from the hospital before they could be questioned carefully.

The incidence of this disease as seen in California demonstrates the occurrence in an almost exclusively white population as compared to most reports in this country that deal with a large Negro population.

Through the courtesy of Medical Director R. H. Creel a large group of male patients at the Marine Hospital in San Francisco were also tested with antigen prepared from our cases. In only 295 of those tested was it possible to obtain a proper reading after forty-eight hours. Many of the positive cases in this series had been previously tested because of clinical evidence of lymphogranuloma inguinale. Table 3 divides the material into two groups. The first group includes patients tested who had been admitted to the hospital for the treatment of venereal disease. The second group includes patients taken at random from other wards in the hospital, not including the venereal ward. The difference in the number of positive reactions obtained in these two groups is striking. The high incidence of positive reactions of patients suffering with other venereal diseases would indicate that lymphogranuloma inguinale is often associated with them.

#### COMMENT

A study of the material presented here leaves little doubt that lymphogranuloma inguinale is a much more common disease in California than has been formerly recognized. Although the number of cases reported here is small and can give only an approximation of the existing conditions, the importance of the disease as a menace to public health cannot be denied. The preponderance of this disease in the Negro race in those sections of the country with a large Negro population is striking. In California, as in many European countries, the preponderance of cases is found among the white population, probably due to the fact that the Negro race is not so much in evidence here. It has been suggested that most of the white males with clinical lymphogranuloma inguinale give a history of sexual contact with Negroes. Our experience would indicate that this assumption is not entirely true. The disease in the white race, at least in this part of the country, occurs most frequently independent of contact with Negroes. Its high incidence in those people subject to frequent sexual contact with sources of venereal infection, regardless of race, would indicate that the infection is more dependent on sexual hygiene than on racial susceptibility.

The relative frequency of positive Frei reactions in patients with no clinical manifestations of the disease and with no history of a previous active lesion cannot be emphasized too strongly. How easily the disease may be transmitted by other means than by sexual intercourse is not known. Many extragenital, primary lesions have been reported in the literature. Undoubtedly many more have been unrecognized and undiagnosed. We feel that the primary lesion may often accompany the initial infection with any of the other venereal diseases and thus go unrecognized. For this

CASE 4.—R. S., a tertipara, eight months pregnant, had preeclamptic toxemia. There was marginal placenta praevia with breech. There was dilatation of two fingerbreadths. Pentobarbital  $4\frac{1}{2}$  grains (0.3 Gm.) was given. Hemorrhage was severe. The cervix was dilated manually sufficient to bring down a foot. Breech extraction was accomplished and resulted in a 6 pound (2,722 Gm.) baby. Resuscitation was difficult, and the baby died suddenly four and one-half hours after birth.

## THE COMPARATIVE EFFICIENCY OF THE COMMONLY USED FLAVOR- ING AGENTS

HAROLD N. WRIGHT, PH.D.  
MINNEAPOLIS

The choice of flavoring agents by the physician for the purpose of disguising the unpleasant taste of various drugs appears to rest largely on an arbitrary basis. All too frequently personal experience with flavoring agents is limited to a few random trials in tasting on the part of the individual physician with the cooperation of a friendly pharmacist.

Fantus<sup>1</sup> has recently advocated the use of a number of new flavoring agents as being superior to some of the older preparations in common use.

With the purpose in view of extending the meager information available with regard to the relative efficiency of the flavoring agents in common use, a group study has been carried on since 1933 with the students of the medical, dental and nursing classes at the University of Minnesota Medical School as part of the laboratory exercises in pharmacology.

The particular points which we have sought to determine in these studies employing relatively large numbers of individuals are which of the commonly used flavoring agents (1) appeal most strongly to the majority of individuals when considered from the standpoint of flavor alone, (2) are most effective in disguising the bitter taste of alkaloids and other bitter drugs, (3) are most effective in covering the saline taste of such drugs as ammonium chloride and sodium bromide, and (4) are most effective in disguising the unpleasant taste of tincture of digitalis.

### METHODS EMPLOYED

The flavoring agents, whether used alone or after the addition of drugs to be tested, were studied in most cases in groups of four flavors at one time, as a larger number of specimens could not be satisfactorily judged and placed in their respective order of efficiency. All preparations were identified only by number or letter. The order of testing the specimens on the part of the students was entirely at random. Each year changes were made in the grouping of the flavors and also in their relative order.

The students were instructed to taste each of the four preparations in turn, rinsing the mouth with water after each, repeating the tasting as necessary, and to decide his or her own order of preference for the taste of the four preparations being tested.

The most effective preparations have been tested on more than 600 individuals. The flavoring agent ranking last in any group was tested for one year only (from 125 to 150 tests). Those flavoring agents which have

been newly admitted to the recent revisions of the United States Pharmacopeia and National Formulary have, of necessity, been tested during the present year only (approximately 175 tests).

The results were tabulated and scored on the basis of 3 points for first choice, 2 for second choice, 1 point for third choice and no credit for fourth choice. The results were then expressed as a percentage of a perfect first choice. Thus a flavoring agent obtaining a score of 75 per cent or more may be considered highly effective, a score in the range of from 50 to 65 per cent indicates a second grade flavoring agent, a score in the range of from 35 to 50 per cent denotes a third grade flavoring agent, and those flavoring agents obtaining a score of less than 35 per cent can be considered practically worthless so far as the preferences of the majority of individuals are concerned.

The reliability of the tests has been checked in a variety of ways. Analysis of the results in groups of from 30 to 35 students (i. e., the number of students making the tests on any one day) shows that even in these small groups the results are consistent from group to group within  $\pm 5$  per cent of the mean values for the class. A check of sixteen groups from the

1936 classes shows an average of  $\pm 4.2$  per cent. Comparison of the results obtained by different classes in each of the four years also shows the results to be consistent within  $\pm 5$  per cent in spite of changes in the grouping of the flavors. A check of twenty-four class results over the four year period shows an average of  $\pm 3.9$  per cent.

### GROUP PREFERENCE FOR VARIOUS FLAVORS

The results obtained in the tests for group preference for the taste of the flavoring agents purely as pleasant tasting vehicles are shown in table 1. It is apparent from an inspection of this table that the flavors which appeal most strongly to the majority of individuals are those of chocolate, the fruit flavors of raspberry, orange, lemon and cherry, and the root beer flavor of sarsaparilla.

It does not necessarily follow that those flavoring agents which are preferred as flavors will be efficient in disguising all or any types of disagreeable tastes of drugs, yet an inspection of the tables shows that all these preferred flavoring agents rank high in efficiency in disguising at least one type of unpleasant taste. It is likewise strikingly noticeable that most of the flavoring agents which rate poorly from the standpoint of preference are usually among those which have proved to be least efficient in disguising unpleasant tastes.

From the Department of Pharmacology, University of Minnesota Medical School.  
1. Fantus, Bernard: *Advances in Therapeutic Technique*, J. A. M. A. 105: 877 (Sept. 14) 1935.

subcutaneous injection of an adequate dose of prostigmin, from 0.5 to 3 mg. The benefit lasts about five to six hours and therefore treatment is given three times a day. As Boothby<sup>11</sup> has emphasized, however, prostigmin medication may be followed by a stage of mental depression and increased weakness developing after the immediate improvement. It is too new a therapy adequately to compare its efficacy with that of ephedrine or aminoacetic acid (glycine).

Since treatment is chronic, oral medication was greatly to be desired. The first report of oral therapy of myasthenia gravis was that of Everts.<sup>6</sup> It was at once apparent that he was using oral doses as high as from ten to thirty times the subcutaneous dose; namely, 30 mg. three times a day. He noted no ill effects in his two patients. It seemed that prostigmin given orally was either poorly absorbed or largely destroyed in the intestinal tract, and therefore large doses were needed. Everts concluded that the drug in the dose he recommended was safe, did not cause gastro-intestinal or other untoward symptoms, and could be used for indefinite periods. One could infer that in order to obtain the gastro-intestinal actions which are known to occur after the hypodermic use of the drug even larger oral doses than those effective in myasthenia gravis might be necessary. With physostigmine, on the other hand, the oral dose is but slightly larger than the parenteral.

On the basis of this report, the manufacturers now supply oral tablets of prostigmin containing 15 mg. each, and the dose recommended on the package for myasthenia gravis is two tablets three times a day. Even larger amounts have been used.

#### PERSONAL EXPERIENCE

One of us (L. S. G.) was engaged in some ergographic and dynamometric experiments to study the effects of prostigmin on skeletal muscle strength and fatigue and was himself serving as a subject. To obtain sufficient drug by the hypodermic route, as it is marketed in 1 cc. ampules containing but 0.5 mg., it was necessary to take a volume of the solution subcutaneously which was both inconvenient and painful. Oral medication was therefore used.<sup>12</sup>

The marked potency of oral physostigmine in small doses made it seem unwise to take the recommended large doses of prostigmin without first trying smaller amounts. Consequently a single one-half tablet dose (7.5 mg.) was taken. When no effects on the heart rate, saliva, pupil or intestine were noted, this dose was gradually increased at intervals (from four days to a week) sufficiently long to rule out all chance of cumulative action. When two tablets (30 mg.) were taken the experimenter noted nothing except a drop in his pulse rate from 73 to 65 per minute. There was no increased peristalsis, miosis, salivation, urinary urgency, muscular twitchings or other evidence of stimulation of "cholinergic" nerve endings. It was therefore concluded that the observation of lack of side effects by Everts was a correct one and that the drug was relatively safe when given orally. L. S. G. took this 30 mg. dose on two occasions several days apart with the results noted, and another subject (A. R.) took this dose on one occasion and noted nothing except a transient slowing of the pulse from 72 to 66 per minute. Atropine was kept at hand to antagonize any

unpleasant symptoms, but these did not occur. As these doses gave no conclusive results on the tests of muscular function examined and also resulted in practically no evidence of parasympathetic activity, it was decided to increase the dose to three tablets after a suitable rest interval (one week). This amount did not seem excessive because of the results noted with two thirds of this dose and the lack of ill effects after the prolonged use of 30 mg. three times daily for months by myasthenic patients. Accordingly, the two subjects mentioned each took a single oral dose of 45 mg. of prostigmin three hours after lunch. The subsequent alarming and unpleasant experience suffered by one of them forms the basis for the warning in this report.

#### REPORT OF CASE

L. S. G. is a perfectly healthy young adult of 74 Kg. whose past history is unimportant. Three hours after a modest lunch, 45 mg. of prostigmin was taken in a single oral dose. During the previous hour, control hand grip readings on a double dynamometer had been recorded once every fifteen minutes and were continued at this interval after taking the drug. This test took only a few seconds, and the remainder of the time was spent reading.

At 2:45 p. m., prostigmin 45 mg. was taken orally. The heart rate was 78 per minute; the pupils were from 4 to 5 mm. in diameter.

At 3:15 the pulse rate was 65. The pupils were normal. There were no symptoms of any sort.

At 4 o'clock there was moderate salivation; the pulse rate was 63.

At 4:30 the last dynamometer reading was made. Salivation<sup>13</sup> was now diminishing. Atropine was not taken, as there were no symptoms to combat. The pupils remained unchanged; the pulse rate was 65.

At 5:15 the symptomless period continued; vision was not impaired; work with a microscope was done with ease.

At 5:30, while the patient was briskly walking home, a matter of ten minutes, sudden excess nasal secretion occurred and lasted for several minutes. Other than this and the slight salivation, nothing untoward was observed.

At 5:45, on arriving home, and three hours after taking the drug, the patient noted excess motor activity in the form of marked restlessness and weaving movements.

At 5:48 there was a sudden moderate desire to defecate; no colic occurred. On the way to the bathroom, the patient suddenly became quite ill and felt "tremulous" all over but was able to call for aid. Within the next few seconds there occurred, in the following order, a distressing feeling of rapid fluttering referred by the subject to the abdomen, diaphragm and thorax, difficulty in breathing, severe giddiness, faintness, and fear of impending death.

At 5:49 the patient was put to bed. He noted that his hands and feet felt like ice, and his wife corroborated the fact that they were very cold and covered with a cold clammy sweat. The face was quite bloodless. The patient was rapidly becoming more and more ill, and respiration was sighing and labored. Atropine was not available. Medical assistance was called. The patient remained conscious throughout and observed his symptoms as closely as possible. A clock on the dresser and a picture in the far room could be seen clearly, so that vision was not yet impaired. No pain was experienced at any time.

At 5:52, coincident with a second exacerbation of the sickening sensation of rapid fluttering in the abdomen and lower part of the thorax, faintness, difficult breathing and a feeling of impending catastrophe, there occurred for the first time twitching of the skeletal muscles starting in the legs and arms and spreading to the intercostal muscles, trunk, neck and face muscles. These twitchings became more widespread, rapid and severe but did not cause pain. The pulse was taken and found to be regular, 75 to the minute, but of very low tension. Faint-

12. Prostigmin tablets were kindly supplied through the courtesy of the Hoffmann-LaRoche Company.

13. Salivation had been noted also by the second subject (A. R.), whose pulse had fallen from 70 to 63 per minute. At this time subject A. R. had slight colic, which was relieved after the passage of a loose stool. He had given 1/100 grain (0.00065 Gm.) of atropine sulfate by mouth and had no more symptoms except for some slight muscle twitchings of the throat later in the evening.

cherry, sarsaparilla, orange, citric acid and cinnamon offering little advantage over one another as second grade flavoring agents. The syrups of wild cherry and licorice and aromatic elixir are the least efficient flavoring and disguising agents.

#### SUMMARY

A group of commonly used flavoring agents has been tested on approximately 600 individuals to determine their relative efficiency in disguising various types of disagreeable tastes.

Considered purely as pleasant tasting vehicles the syrups of prepared cacao and raspberry are the flavors of choice of the largest percentage of individuals. Second choices are the syrups of orange, cherry, sarsaparilla and citric acid.

The syrups of raspberry, eriodictyon and prepared cacao are the flavors of choice in disguising the taste of bitter drugs such as alkaloids.

The syrups of cinnamon, orange and sarsaparilla are the most effective agents in disguising the salty taste of such drugs as ammonium chloride and sodium bromide.

The syrups of raspberry and prepared cacao are the flavors of choice in disguising the taste of tincture of digitalis.

The most efficient "all-purpose" flavoring agents of the group studied are the syrups of prepared cacao and raspberry.

## INCIDENCE OF LYMPHOGRANULOMA INGUINALE IN SAN FRANCISCO

ARTHUR HAIM, M.D.

AND

CARLETON MATHEWSON JR., M.D.

SAN FRANCISCO

Lymphogranuloma inguinale has become recognized throughout the civilized world as a relatively common disease. Numerous articles on this subject have been published in North American medical journals during the past year, remarkably few, however, from the western part of the United States.

The object of this paper is primarily to stress the incidence of lymphogranuloma inguinale in California. We hope that, through the stimulation of a general interest in this disease in California, sufficient material will become available to facilitate a more thorough study of its clinical manifestations, treatment and prevention. If the opinion of European authorities is to be accepted, we are confronted with a widespread, extremely chronic and devastating disease which is eventually fatal in its termination. With our present knowledge, the only means of control of the disease lies in the field of preventive medicine. Published reports would indicate that the disease is becoming more and more prevalent throughout the civilized world; consequently its recognition and prevention in California are immediate issues of paramount importance.

The term "lymphogranuloma inguinale" used in this article is a poor descriptive name for the disease. We have continued its use since it is the term accepted by the American Medical Association and the Health Organization of the League of Nations.

A review of the extensive foreign and domestic literature on this subject has been purposely omitted here. Detailed information dealing extensively with the historical, clinical, epidemiologic and experimental features of lymphogranuloma inguinale may be found in excellent monographs published by Hellerström,<sup>1</sup> Stannus<sup>2</sup> and Wassén.<sup>3</sup>

In 1934 Templeton and Smith<sup>4</sup> reported one of the early cases of lymphogranuloma inguinale seen in California. They did not mention an article published by Hoffman<sup>5</sup> in 1933 in which he reports eleven cases. Eight of Hoffman's patients contracted their infection in California. In 1935 Novy<sup>6</sup> published the report of a case that originated in northern California. In his article he mentions thirteen cases observed by Stewart at the Marine Hospital in San Francisco and three additional cases seen elsewhere in California. Stewart's patients acquired their infection, with one exception, in foreign ports. Hoffman in a discussion of Novy's article classified the thirty-five cases seen since March 1933 in the urologic service of the Los Angeles County Hospital as follows: twenty-seven males, eight females, sixteen Americans (white), ten Mexicans, seven Negroes, two Filipinos; source of infection: Los Angeles County twenty-seven, Texas four, Mexico one, Minnesota one, Philippine Islands one and unknown one. Diepenbrock, McGinnis, Yoell and Morgan<sup>7</sup> reported two infections contracted in northern California.

This account includes all the information that we were able to gather from the literature on the occurrence of this disease in California. Other publications may have escaped our attention. Needless to say, a great many cases have been properly recognized but not reported; e. g., those from the Marine Hospital in San Francisco, where the Frei test has been in use since 1934. There are close to sixty proved cases on record at that hospital alone. In San Francisco, antigen for Frei tests has been available at the Hooper Foundation during the past three years. Many of the clinics and private hospitals have used the antigen intermittently for a considerable period. To our knowledge, however, there has been no systematic survey of this disease in northern California. Our material consists of forty-six proved cases of lymphogranuloma inguinale with clinical manifestations of the disease, together with a preliminary account of a survey comprising a group of 700 persons in San Francisco. The clinical and pathologic features of lymphogranuloma inguinale and the rectal manifestations of this disease have been considered by us elsewhere.

#### DIAGNOSIS, ESPECIALLY BY MEANS OF THE FREI TEST

The Frei test plays the most important rôle in the diagnosis of lymphogranuloma inguinale. In the begin-

each bout of intestinal activity was followed in a few seconds by definite accentuation of skeletal muscle twitchings.

It is also of interest that those muscles which are most involved in myasthenia gravis—eyelids, extraocular muscles and face, lip, tongue, throat and neck muscles—still contracted after other muscle groups had ceased and were most painful during the following forty-eight hours.

The persistence of consciousness during physostigmine poisoning was also noted in this case. The spasm of accommodation and the miosis were quite typical. Oddly enough, no lacrimation was observed, although the sudden short spell of nasal discharge may in reality have been due to tears. The pulse, slow in proportion to the degree of shock and evidently low blood pressure, was characteristic of this type of poisoning.

Atropine is a specific physiologic antagonist, and the relief it brought in this case is clear. It was more effective on parasympathetically innervated organs than on the skeletal muscles. Indeed, no parasympathetic innervation of voluntary muscle has ever been proved, and some workers doubt whether atropine directly overcomes physostigmine-induced muscle tremors. The iris was relaxed before the bowel. The later return of mild symptoms was undoubtedly due to the wearing off of atropine action and indicates that prostigmin was still acting eight hours after ingestion.

The considerable caution observed in testing out smaller amounts before taking a 45 mg. dose of prostigmin has been recited in some detail, and it should be repeated here that, when two thirds of the latter dose was taken on several occasions by two observers under controlled conditions, absolutely no signs or symptoms appeared other than a slight cardiac slowing. Whether poisoning would have occurred in subject A. R. had he not taken atropine is unknown. The long interval before the appearance of poisoning must be reemphasized, because large oral doses are given every four to six hours to myasthenic patients.

It is easy to see how any delay or irregularity in absorption or destruction of the drug could cause cumulative action and poisoning in these patients. That such reports have not yet appeared is no guaranty of safety. There is not the least reason to believe at present that myasthenia gravis patients are more tolerant to the physostigmine group of drugs. To superimpose the alarming and distressing symptoms reported here on a myasthenia gravis patient or a postoperative patient with abdominal distention might produce tragic results.

It is a general rule of pharmacotherapy that, when alkaloids potent in small subcutaneous doses are not effective orally except in very much larger doses, much must be learned about the fate of the drug in the gastro-intestinal tract before oral use can be recommended. To our knowledge, nothing is at present known about the fate of prostigmin. Since a number of variable factors, such as amount of chyme in the intestinal tract, gastric emptying time, destruction of the drug by enzymes, rate and site of absorption, and time of administration of drug in relation to meals, may be concerned, we feel that the present practice of giving orally thrice daily from ten to thirty times the effective subcutaneous dose is dangerous. An unfavorable combination of the various factors controlling the absorption, fate and excretion of the drug may result in poisoning.

If prostigmin is needed in myasthenia gravis, we suggest that for the present it be given parenterally, so

that dosage can be controlled. If the latter is impossible, it seems wisest to rely on other therapeutic measures until more is known concerning oral prostigmin. We also feel that any claims that prostigmin is less toxic for man than physostigmine and has a higher therapeutic index should be reserved until more clinical evidence is available.

## THE ALLANTOIN TREATMENT OF ULCERS

THEODORE KAPLAN, M.D.

NEW YORK

Chronic, stubborn, nonhealing ulcers of the leg constitute one of the most annoying conditions that the profession is called on to treat. A superficial ulcer often develops into a deep one involving the subcutaneous tissues and even resulting in a periostitis of the underlying bone. The usual accepted treatment for this type of ulcer has included rest in bed, wet dressings, various ointments and lotions, skin grafts, excision of necrotic areas, adhesive strapping over ulcerated areas, and injection of varicose veins.

These traditional approaches to healing, however, have in many cases been unsatisfactory and have failed often to effect a cure. In view of the fact that there is not, as yet, a satisfactory specified method of treating these stubborn and nonhealing wounds, I am suggesting the use of allantoin.

Allantoin has been found to have the same effects on surgical wounds as maggots; namely, the removal of infected material and the stimulation of healing through the growth of healthy granulation tissue.<sup>1</sup>

Maggots, investigation has disclosed, secrete into diseased tissue a definite substance which cleanses the wound, promotes the growth of vascular granulations and puts the flesh in a healthy state.<sup>2</sup> Allantoin, characteristically, removes necrotic material and promotes the growth of granulation tissue and rapid healing. Since maggots and allantoin are found to produce the same results, it may be that allantoin is the important agent in the maggot excretion, although there may be other contributive components. Furthermore, allantoin, or the healing agent, is of such a nature that it can be obtained from sources other than maggot excretion. Specimens of maggot excretion, both sterile and non-sterile, are found to contain allantoin. It is found in the excreted end-products of purine metabolism in all arthropods, not only maggots. It is also widely distributed among plants. Macalister<sup>3</sup> found it conspicuously present in the roots of comfrey, a plant prized by European peasants for its curative properties.

Chemically, allantoin is the principal terminal product of purine metabolism in animals below man and the manlike apes, and it results from oxidation of uric acid through the action of the enzyme *uricase*. In its commercial form, allantoin is prepared by Merck & Co. It is a white, odorless, stable, bland crystalline powder, slightly soluble and nontoxic. To adapt it for use in wounds, it must be dissolved as follows: Two

A supply of allantoin is available from the U. S. Department of Agriculture, who also supply information on Nonhealing Wounds, of Wide Biological Interest.

organisms on the smear and no growth on culture material. Frei tests were positive in all cases.

Frei antigen was prepared from the pus aspirated from the inguinal glands of many of these patients. In every instance the antigen prepared gave positive skin reactions in known cases of lymphogranuloma inguinale and negative reactions in controls.

Eight of these patients gave histories of a transient sore on the penis from eight to twenty-one days following exposure.

Complete surgical extirpation of the diseased inguinal glands resulted in prompt and complete healing in eight cases. There has been no recurrence to date in any of the patients so treated, one of whom we have had under observation for a period of about two years. The dreaded elephantiasis of the genitalia following bilateral extirpation of the inguinal glands, reported by many writers, did not occur in any of these cases. A unilateral inguinal adenitis in one patient disappeared following a single aspiration of pus and prolonged treatment with intravenous injections of Frei antigen. This specific antigen therapy is being carried out in a series of patients under our care at present. Incision and drainage without extirpation of the diseased glandular tissues resulted in persistent fistulas in four cases. In two others, spontaneous regression of the inguinal buboes followed a course of intravenous antimony and potassium tartrate.

The transient nature of the primary lesion in many cases is well demonstrated in the following case:

A. T., a white woman, aged 22, an American, was brought to our attention as the last sexual partner of a Mexican being treated in the San Francisco Hospital for a bilateral inguinal adenitis due to lymphogranuloma inguinale. Their sexual relationship began March 12, 1936, and continued for several weeks until he became ill and was admitted to the hospital for treatment of the genital lesions.

Suspecting the venereal nature of her partner's illness, the patient underwent an examination by her private physician and was pronounced free from disease. On examination at the San Francisco Hospital May 4, the patient stated that she had been perfectly well until about the middle of April, when she noticed some slight pain in the right inguinal region when standing for long periods of time or when walking for long distances. This pain had been improving since that time. She also noticed "a burning sensation within the vagina" when walking. She stated that there was no vaginal discharge and no fever of which she was aware.

Physical examination revealed no adenopathy with the exception of a tender, freely movable gland about 1 cm. by 1 cm. in the right inguinal region and a smaller nontender gland in the left inguinal region, which also was movable. Just below and to the patient's right of the urethra was a small superficial ulceration from 0.5 to 1 cm. in diameter. The surface was covered with a gray exudate. At the lower margin of the ulcer was a small nodule of granulation tissue. The lesion was slightly tender to pressure. The margins were not indurated. The cervix was clean, virgin.

A smear from the lesion showed numerous micro-organisms, none, however, resembling gonococci or Ducrey's bacilli. Dark-field examination for spirochetes was negative. The Wassermann and Kahn reactions were negative. The Frei test was positive with three separate antigens. The chancroid reaction was negative.

May 6 the ulcer was cleaning and healing slowly. May 13 the patient was completely afebrile. The primary lesion was smaller and clean, but there was still some ulceration. The gland in the right inguinal region was smaller and no longer tender. May 20 the inguinal glands were smaller. The primary lesion had decreased in size so that now there was only a very small area of granulation tissue in the central portion of a depressed scar. May 27 there was a minute remainder of granulation tissue. The inguinal nodes were small and not tender. June 3 the primary lesion was healed. There was a small depressed

scar (0.5 cm. in diameter) at the site of the previous ulceration. Inguinal nodes were no longer tender. The patient was advised to return in one month for further examination. No local or general therapy was recommended.

The primary lesion in this patient was of such a minor nature that she certainly would not have submitted to a second examination had she not been requested to do so because of a positive Frei test. During the period of vaginal ulceration the patient was undoubtedly highly infectious. The inguinal adenitis as well as the vaginal ulceration disappeared completely without treatment. The patient would have been entirely unaware of having had the disease had she not had the second examination. The negative history of a primary lesion in many patients suffering with secondary manifestations of the disease may be explained on this basis.

#### CASES PRESENTING RECTAL MANIFESTATIONS

During the past four years we have collected at the San Francisco Hospital twenty-three cases presenting rectal manifestations of this disease. In all patients we have been able to prove the presence of lymphogranuloma inguinale by positive Frei tests and to rule out certain other etiologic factors, particularly by the use of biopsy material. Certainly not all benign strictures of the rectum can be attributed to lymphogranuloma inguinale. Many other etiologic agents have been suggested, the most prominent being syphilis, gonorrhea, tuberculosis and amebic dysentery. No doubt certain incidents of rectal stricture can be traced directly to one or the other of these diseases. However, the frequent finding of a positive Frei test in patients suffering with benign rectal stricture is strong evidence in favor of this disease being the real etiologic factor in the majority of cases.

In fifty-one patients treated for benign rectal stricture in the San Francisco Hospital from July 1, 1919, to July 1, 1934, the clinical evidence of lymphogranuloma inguinale together with the absence of other etiologic factors make it plausible to assume that at least thirty-two of these patients should come into the category of this disease. Had Frei antigen been available during that period, the majority of these patients would undoubtedly have shown a positive reaction. Many of the patients with benign stricture of the rectum whom we are now treating for lymphogranuloma inguinale were admitted to the San Francisco Hospital in the local pre-Frei era under the diagnosis of syphilitic or gonorrheal stricture of the rectum. These diagnoses, as we now know, were erroneous.

The clinical and pathologic features of this particular manifestation of lymphogranuloma inguinale will be considered by us in another article.

#### IMMUNOLOGIC DIFFERENTIAL DIAGNOSIS OF LYMPHOGRANULOMA INGUINALE AND CHANCROID

During the past three months we have performed skin tests with a chancroid antigen on all patients in the San Francisco Hospital who have given a history of venereal disease associated with an inguinal adenitis. We have also performed the test during this period on all Frei-positive patients.

The chancroid antigen was prepared from pus obtained from a suppurating inguinal gland in a patient seen in April 1936 and suspected of lymphogranuloma inguinale but in whom Frei tests with previously tested Frei antigens were consistently negative. The dmecos skin test for chancroid (antigen obtained by courtesy

position for four years, when she was married. Her economic status after marriage was inferior to her previous level, and she was forced to drudging household labor. Two years after marriage her first child was born. During the puerperium she became depressed and agitated and remained so for six months, when she recovered after a brief period of maniacal excitement for which she was hospitalized. A second pregnancy three years later was attended with the same symptoms. She remained well after this until January 1936.

At Christmas 1935 the patient and her husband attended a party at the home of a former schoolmate who was decidedly more affluent than the patient. During the party the patient's husband noticed that she was dull and listless and he urged her to drink and be more convivial. After each drink she became duller and finally she became unconscious. She was taken home, where she recovered consciousness but stated: "I feel strange like I did after the babies came." She went to her family physician feeling depressed and unable to concentrate. Thereafter she visited him at weekly intervals. She continued to be depressed and cried a great deal and thought herself responsible for her husband's lack of financial success and worried about the children. The physician decided to employ a preparation of hematoporphyrin hydrochloride<sup>3</sup> intramuscularly in doses of 1 ampule at weekly intervals. The first dose was given the second week in May. In the early part of June the patient complained of weakness of the legs. By the end of the third week in June the patient would not arise from bed and complained of some pain in the legs and right arm. At that time my examination showed that there was weakness and incoordination of both legs and the right arm. Deep sensation (sense of position and vibratory sense) was lost in both legs and impaired in the right arm. Patchy areas of hypesthesia for pain were also noted in these areas. No tendon reflexes were obtained in the lower extremities. There was no response to plantar stimulation. The patient still complained of painful paresthesias.

Administration of hematoporphyrin was stopped in the first week in July. By the middle of July all the neurologic signs noted had practically disappeared. The mental state was unchanged except that the patient was more agitated and self accusatory, so that the psychotic picture has acquired an involutional coloring. During the administration of the hematoporphyrin hydrochloride no hematoporphyrinuria was noted in this patient.

#### COMMENT

The symptoms and signs of peripheral multiple neuritis in this case occurred following administration of hematoporphyrin hydrochloride and disappeared when the drug was discontinued, so that I believe it is fair to indict the drug for the neuritic syndrome. Likewise no other cause was found that might be responsible for the neurologic signs.

Some further justification of this indictment may be adduced from the literature concerning hematoporphyrinuria and neuropsychiatric disturbances. The occurrence of these phenomena in conjunction with dysfunction of the nervous system (Landry's syndrome) was noted by Erbslöh<sup>4</sup> and since then similar reports have been made by Courville,<sup>5</sup> Lhermitte,<sup>6</sup> Abderhalden,<sup>7</sup> Beilin<sup>8</sup> and others. All these cases were fatal. Also psychotic disturbances have been described by Eichler,<sup>9</sup> Thiele<sup>10</sup> and Courville.<sup>5</sup> Muscle atrophy associated with disturbance caused by hematoporphyrinuria is reported by Sachs.<sup>11</sup>

Most of the cases of neuropsychiatric disturbance with hematoporphyrinuria have occurred after administration of drugs such as sulfonmethane, but some have shown no assigna-

ble cause for the presence in the urine of such a substance. Recoveries<sup>12</sup> have been noted from neuritis associated with hematoporphyrinuria. The pathologic pictures presented by these cases are largely degenerative lesions of the cortex cerebri and substantia grisea of the spinal cord. Some degenerative lesions of the peripheral nerves have been found. Other cases reveal no demonstrable lesions of the central or peripheral nervous system.

#### CONCLUSIONS

The case of peripheral multiple neuritis here presented was presumably due to the administration of hematoporphyrin hydrochloride for the treatment of a psychotic depression.

#### A NEW DANGER: ASPIRATION OF CARBON DIOXIDE SNOW

MAX L. SOM, M.D., AND A. HARRY NEFFSON, M.D., NEW YORK

With the recent introduction of carbon dioxide snow, better known as "dry ice," for general commercial use and the ease with which it can be obtained by irresponsible persons there have come grave dangers of accidental misapplication. Following the occurrence of the case to be reported, inquiry among the children in the neighborhood revealed that one of their diversions is to obtain the "ice" at a candy store or from a traveling vender with a purchase of ice cream and to place a small piece in the mouth and blow off "steam." Occasional cases of small burns of the mouth have apparently not sufficed to put an end to this practice.

A review of the literature during the past ten years shows this to be the first case of its kind to be reported.

#### REPORT OF CASE

V. K., a boy, aged 7 years, was admitted to the laryngologic service of Mount Sinai Hospital Sept. 27, 1936, with a history of having "swallowed" a piece of "dry ice" the size of a grape twenty minutes before admission. Following this he "choked, got blue and fainted." His mother tried to remove the "ice" digitally but was unsuccessful. He regained consciousness and his mother brought him to the hospital at once.

On admission his color was good and breathing was easy. There were no inspiratory retractions but there was a moderately loud, low-pitched expiratory stridor, simulating the sound of a snore (such as is heard in patients with supraglottic edema, as described by Neffson and Wishik<sup>1</sup>). Swallowing was so painful that he spit constantly. Indirect laryngoscopy revealed more than moderate edema of the left arytenoid and aryepiglottic fold, preventing visualization of the left vocal cord. The right side of the larynx, the epiglottis and the pharynx looked normal. Breath sounds were well transmitted throughout the chest. The rest of the physical examination was essentially negative.

During the next hour and a half the stridor increased somewhat, supraclavicular retractions appeared, but breathing still remained quite easy. On reexamination by indirect laryngoscopy the epiglottis, aryepiglottic folds and arytenoids were found to be so extremely edematous that the glottis could not be seen. Because of the rapid progression of the laryngeal edema in so short a time, it was realized that a tracheotomy would be required. The larynx was sprayed with a cocaine (20 per cent)-epinephrine (1:1,000) solution preliminary to tracheotomy. He immediately became extremely dyspneic, with deep retractions and a loud, crowing, inspiratory stridor, slightly cyanotic, very restless and anxious looking. What had evidently occurred was a sudden indrawing of the edematous supraglottic tissues into the glottis, with consequent acute respiratory obstruction.

A bronchoscope was introduced at once and gave immediate complete relief. It was noted that the trachea was intensely congested and edematous. With the bronchoscope in place, an

reason we believe that any venereal infection should be considered as a potential mixed infection and that the Frei test should be used in these cases just as frequently as the serologic examination for syphilis.

The multiplicity and extreme seriousness of the late manifestations, the inefficacy of all known methods of treatment and the relative frequency of lymphogranuloma inguinale emphasize the importance of its early recognition and prevention. The public health measures necessary in the prevention of this disease will become evident only through a more comprehensive knowledge of its occurrence and epidemiology. We hope that by placing reliable Frei antigen at the disposal of the medical profession at large and by stimulating their interest we may collect sufficient material to facilitate a more extensive study of the disease in this community.

#### CONCLUSIONS

1. Lymphogranuloma inguinale is not uncommon in northern California, as shown by a collection of forty-six proved cases and a general survey of 700 persons in San Francisco.

2. The transmission of the disease is not dependent on racial susceptibility.

3. The frequency of the disease in the white population of this community emphasizes its public health importance.

### THE THERAPEUTICS OF PROSTIGMIN

#### A WARNING CONCERNING ITS ORAL USE BASED ON A PERSONAL EXPERIENCE

LOUIS S. GOODMAN, M.D.

AND

WILLIAM J. BRUCKNER, M.D.

NEW HAVEN, CONN.

Prostigmin<sup>1</sup> is a new synthetic drug closely related chemically and pharmacologically to physostigmine (eserine). It belongs to the class of drugs known as parasympathomimetic agents. Other drugs in this general group are pilocarpine, and choline and its derivatives. The recent experience to be reported herein can best be appreciated after a brief review of the pharmacology and therapeutics of prostigmin.

#### PHARMACOLOGY AND THERAPEUTICS

Prostigmin and physostigmine have a unique manner of acting on the nervous system which has been elucidated only in recent years. Whereas pilocarpine acts by directly stimulating the "receptive substance" at the endings of parasympathetic nerves, physostigmine and its analogues have no such effect. It is now known that certain nerve endings release minute amounts of a chemical substance when they are stimulated, and that this chemical mediates the nerve impulse to the effector organs. For parasympathetic nerves this substance is acetylcholine. An enzyme in the tissues and blood constantly and rapidly destroys this acetylcholine, so that its effects are transient and localized. This enzyme, known as cholinesterase, splits acetylcholine to choline, which is extremely weak compared to its ester. Physostigmine inhibits this esterase and thus preserves or "fortifies" the acetylcholine liberated at nerve endings. Acetylcholine itself and its more stable congener, acetyl-beta-methylcholine (Mechoyl), have recently been intro-

duced into therapeutics to represent in themselves the chemical mediator of parasympathetic (and certain other) nerve impulses.

Prostigmin is said to be less active than physostigmine on the eye (less miosis and spasm of accommodation), and less depressing to the heart and blood pressure.<sup>2</sup> It retains the typical action on the intestine, namely, an increase in tone and peristalsis, and was introduced into therapeutics as an agent effective in the prevention and relief of abdominal distention due to paralytic ileus.<sup>3</sup> Physostigmine is used for this purpose but the occasional unpleasant cardiovascular effects sometimes prevent the use of doses sufficiently large to be effective on the bowel.

Very recently, prostigmin was found to be effective in the symptomatic therapy of myasthenia gravis. Ever since the West African natives were forced during "trials by ordeal" to chew the calabar or "ordeal" bean (source of physostigmine), it has been known that the drug could cause marked skeletal muscle twitchings as well as the typical symptoms of parasympathetic stimulation. It was also known that physostigmine was a physiologic antagonist to curare and that in some respect myasthenia gravis resembles mild curare poisoning. Walker<sup>4</sup> had experimented with physostigmine in these patients with some benefit and, when prostigmin became available, used it in her cases.<sup>5</sup> In barely two years, the drug has gained wide use in the symptomatic treatment of this disease.<sup>6</sup> The mechanism of its action still remains a mystery, although several important leads exist. Dale, Feldberg and their co-workers<sup>7</sup> have demonstrated that acetylcholine is also released at the spinal nerve terminals of skeletal muscle. Thus, somatic nerves to muscle are "cholinergic." The twitching so characteristic of physostigmine poisoning thereby became understandable, but in myasthenia gravis there is as yet no evidence to indicate any disturbance of the acetylcholine-esterase system. In fact, it was shown by Stedman<sup>8</sup> that the blood esterase values in this disease tend, if anything, to be lower than normal. More recent work by McGeorge<sup>9</sup> and by Hall and Lucas<sup>10</sup> on a large number of normal and pathologic serums including cases of myasthenia gravis indicates that esterase values remain remarkably constant in health and disease. Myasthenia patients were well within the normal range of esterase variation.

In myasthenia gravis, striking improvement is noted in some cases in from ten to thirty minutes after the

preparation could be used to advantage in combating the convulsions under discussion.

In a previous article, we<sup>2</sup> reviewed 137 cases which had been reported in the literature and added seven more, while six others were omitted because of insufficient information. Woolmer and Taylor<sup>3</sup> have furnished a good description of a typical case: "The patient is a child or young adult with pyrexia, usually due to some acute septic condition. The theater is overheated. Atropine has been given and the dose may have been excessive. The patient is deeply anesthetized with ether, the pupils being dilated and inactive to light. The color is, as a rule, good, and oxygenated ether is sometimes being given. The eyelids start to twitch, then the face, and the convulsions become general. In the immediately fatal cases, after five to ten minutes of convulsions, the respiration ceases, the patient goes blue, and the heart stops; in other cases the convulsions stop but the patient dies later from cardiac failure; alternatively, recovery may follow the cessation of the convulsions."

The clinical picture may differ in some details from this description, but this is as typical as any other description would be, and after noting at least thirty-three various causes or significant factors which have been mentioned in the literature as probable etiologic factors, one feels that more than the average care should be exercised in the selection of an anesthetic for a patient who is young and who is suffering from marked toxicity, presumably of an infectious type, and that general anesthetics cannot be used with safety in all such cases. It might be well to resort to the use of local anesthesia and to employ a sufficient amount of barbiturates in preliminary medication to minimize convulsive efforts. Tribrom-ethanol no doubt could be used to advantage, and perhaps even intravenous anesthesia might be used. If general inhalation anesthesia is to be used, it should be used cautiously.

#### SUMMARY

We suggest that if all precautions have been followed, and if convulsions occur, an anticonvulsant should be used to combat them while such other treatment as may seem indicated in a given case also should be employed.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

HOWARD A. CARTER, Secretary.

### DOMESTIC PORTABLE DIATHERMY MACHINE NOT ACCEPTABLE

Manufacturer: Domestic Diathermy Company 1775 Broadway, New York.

The Domestic Portable Diathermy Machine is a small unit which is advertised and sold directly to the public by lay salesmen, who are provided with pamphlets and testimonials of lay users. The instruction for its use is given largely by the salesmen. When closed it resembles a portable typewriter case. The front lifts off, disclosing a panel on which there is one regulator on the right hand side numbered 1 to 5 and on the left hand side. Another regulator is marked "Hi" and "Lo." Below these controls in the center there is an ammeter. The current is applied by electrodes.

A copy of a pamphlet entitled "Diathermy Comes to Your Home," which has been referred to the Council, contains such statements as "Thousands of persons in every walk of life have learned to use the DOMESTIC PORTABLE DIATHERMY MACHINE . . ."; "To you, the sufferer—we offer a free test of this amazing diathermy unit, to determine whether your specific condition will respond to this method. This test may be conducted right in your own home—without any expense or obligation to you, whatsoever."

An advertisement for the Domestic Diathermy Machine which appeared in the Nov. 22, 1936, issue of the New York *Herald Tribune* contained the following statements: "In hospitals

and physicians' offices and in the home Diathermy's deeper inner penetrating heat ALONE has wrought an impressive achievement in soothing away the crippling anguish of Arthritis, Rheumatism, Sciatica, Neuritis, Lumbago, High Blood Pressure"; "For further details about the application of this amazing medical unit in the home or how to obtain the Diathermy Test, without the slightest obligation, write Dept. H. or 'phone," and "Domestic Diathermy Company operates with consent and supervision of the medical profession."

In the opinion of the Council on Physical Therapy, the Domestic Diathermy Company is practicing methods that are detrimental to rational therapeutics. The use of promotional sales methods by those unqualified to practice medicine constitutes an appeal to the public with arguments which are unscientific and may harmfully enhance a feeling of false security on the part of the public.

In view of the foregoing, the Council voted not to include the Domestic Diathermy Machine in its list of accepted devices.

### ALLERGEN-PROOF ENCASINGS ACCEPTABLE

Manufacturer: Allergen-Proof Encasings, Inc., 4046 Superior Avenue, Cleveland.

The Allergen-Proof Encasings are made for covering mattresses, pillows and box springs for the protection of those allergic patients who are sensitive to dust, feathers, cottonseed or kapok. Dust sensitive, in this instance, refers to the reaction of those individuals who come in contact with mattresses, feather pillows and other causes of dust in sleeping quarters.

These encasings may be obtained for various sized mattresses, pillows and box springs and are made of material that is in itself dust proof. The openings are provided with slide fasteners, thus making the joints practically dust tight. The material of which the encasings is made is a product of the du Pont Company, a rubber fabric composition treated by a new process which increases the resistance of rubber to oxidation. These products have been tried out in several institutions acceptable to the Council and reports received are summarized as follows:

1. The material is essentially dust-proof and is capable of effectively holding back the dust from mattresses and pillows.

2. In dust-sensitive patients there results definite improvement in consequence of eliminating this mattress and pillow dust.

3. The special material submitted is capable of withstanding rough treatment and scrubbing with hot water and soap to a greater degree than the usual rubberized cloth.

4. The material may deteriorate in a year's time and thus, in some instances, need replacement.

In view of the favorable reports received concerning the efficacy of the Allergen-Proof Encasings, the Council on Physical Therapy voted to include them in its list of accepted products.

### CONDUCTO-THERM NOT ACCEPTABLE

Manufacturer: Conducto-Therm Corporation, Los Angeles.

According to the firm, the Conducto-Therm is an electric blanket designed for administering fever therapy. The temperature of the body is raised and maintained by the application of conductive heat and the prevention of heat losses. The apparatus consists essentially of two parts: (1) a step-down transformer used to supply the heating element in the blanket with an electric current of low voltage, and (2) a heating element incorporated in the blanket itself, in which the patient is wrapped during the administration of treatment. The foundation of the heating element consists of a piece of 8 ounce duck 66 by 78 inches. On this duck, resistance wires running the length of the material are stagger-stitched in parallel. There is furnished a rubber sheet, 70 by 84 inches, which is used as a protective covering for the heating element. The intensity of the current may be controlled, thus providing various degrees of heat.

In a clinic acceptable to the Council, the Conducto-Therm was tried out under actual conditions. It was observed that a longer period of time is required for the establishment of tem-

2. Lundy, J. S.: Convulsions Associated with General Anesthesia, to be published.

ing was forestalled by hanging the head over the edge of the bed. The entire body felt and remained cold despite the rapid application of many blankets and hot water bottles.

At 6 o'clock another severe syncopal "spell" occurred and lasted fully one minute, during which the patient was too breathless to talk, noted a great increase in the fluttering sensation in the abdomen and thorax, remained conscious only with great difficulty, and observed that the skeletal muscle switchings were now involving almost every voluntary muscle in the body. These tremors and clonic contractions were now plainly visible in the arms, neck and eyelids and could be felt in the throat. Some dysarthria was noted. Spasm of the accommodation was surmised from the fact that the objects in the next room could not be seen very clearly any longer but that near objects and the clock on the dresser, which was watched anxiously while awaiting the arrival of assistance, could still be seen.

At 6:05 a fourth severe "spell," marked by yet another sharp intensification of all the symptoms and signs mentioned, occurred and lasted fully two minutes. By now the patient was greatly exhausted from the muscular activity and the contemplation of possible consequences. Random compulsive movements accompanied the tremors and muscle contractions. The pulse remained regular at about 75 but seemed to be weaker. For the first time, slight intestinal colic occurred and some flatus was passed. Slight nausea was noted.

At 6:10 Dr. W. J. B. (co-author of this report) arrived and noted immediately the state of shock. The pulse was now 70 and very weak but regular. The pupils were small and measured about 2 mm. or less but still reacted to light, a characteristic of physostigmine. The onset of eyelid and lip twitchings prompted examination of the tongue, which showed marked fibrillary tremors on which were superimposed coarser contractions. Unfortunately no instrument was available to measure the blood pressure. The patient was ashen gray and very restless, and a cold sweat persisted on the face and hands.

At 6:15 atropine sulfate one-fiftieth grain (0.0013 Gm.) was given intramuscularly. A fifth, more severe and sudden, exacerbation of all symptoms and signs again occurred, and this time the marked tremor of the abdominal wall prompted examination of the abdomen. On inspection, the abdomen presented the miniature of a storm at sea. Marked and rapid peristaltic and pendular intestinal movements were producing bizarre pulsations and undulations. The superimposed twitching of the voluntary abdominal musculature which could so easily be felt by the patient could be seen only with difficulty, whereas the violent intestinal activity manifested itself in consciousness only as a sickening, ill defined tremulousness. It seemed very possible that each "spell" was initiated by a violent bout of intestinal overactivity, and yet no pain, griping or urgency to go to the stool was noted.

At 6:30 the pupils were still small. The abdomen was somewhat quieter. The voluntary muscles were contracting as markedly as ever and now involved the eyelids, tongue, lips and throat muscles even more than the extremities. The heart was quite normal except for an easily detectable apical systolic murmur, which had not been noted previously on many physical examinations. The cardiac rate was regular and about 70 to the minute, the low tension persisting. The restless movements continued. The case was being actively discussed by the patient throughout so that no part of the picture might be overlooked.

At 6:35 the oral temperature was taken and found normal. Pain was felt for the first time but only in the eye muscles.

At 6:40 the abdomen still presented the activity described, and the hyperperistalsis was both audible with the stethoscope, and palpable. The first urgency to defecate was felt and the patient was helped to the bathroom and passed a small diarrhetic stool. The state of shock was less severe. Sweating ceased and the ashen pallor was less evident.

At 6:45 the pupils were by now slightly larger, and distant objects again appeared clear. The mouth began to feel somewhat dry.

At 6:55 the intestinal activity quieted rapidly but the voluntary muscles continued twitching. The patient was subjectively improved.

At 7 o'clock the hands and feet became warmer and drier and the patient felt well again. It was only at this time that the medical attendant felt it safe to leave. Despite the continuation of the muscular tremors, handwriting was not

impaired, and the clinical observations noted in this report were recorded at this time. During the ensuing hour all symptoms subsided rapidly.

At 8 o'clock the patient felt well enough to get out of bed. The skin color was greatly improved. Fatigue was marked. The tongue tremor was still noticeable but the twitchings of other muscles, though subjectively felt, could no longer be seen definitely. Some urgency of urination occurred and transient left sided sharp pain interpreted as ureteral in origin was experienced.

*Subsequent Course.*—Recovery was rapid. Dinner was eaten and retained. A very mild return of muscular tremors and intestinal symptoms occurred about 10 p. m. but soon yielded to oral atropine sulfate, one-fiftieth grain. Sleep proved impossible, owing to the slight but persistent feeling of generalized muscle tremulousness, until sodium amytal was taken.

For the following two days the patient noted marked muscle soreness, especially of the eyes, neck and throat muscles and abdominal wall. Slight fibrillary tremor of the tongue was still clearly seen twenty-four hours later. In addition, fatigue, restlessness and hyperperistalsis continued throughout the next day but did not interfere with the patient's usual routine. The patient's muscles felt as if he had performed violent and unaccustomed physical exercise. The systolic murmur no longer was evident.

#### COMMENT

There can be no doubt that the case here reported is one of severe poisoning due to prostigmin. All the classic signs of physostigmine intoxication were present. The order of appearance is of some interest and importance. The heart rate fell within thirty minutes after taking the drug and reached its lowest level in one and one-half hours. Thus, cardiac vagal endings appear to be more sensitive to the drug than other parasympathetic endings. It also indicates that no delay in drug absorption occurred. Salivation was not noted until one and one-half hours after taking the drug and only after the heart rate was maximally slowed. This held true for both subjects. Soon after the chorda tympani stimulation resulted in salivation, the intestinal discomfort was noted in subject A. R.

The long latent period (ninety minutes) between salivation and sudden onset of shock and intestinal and skeletal muscle activity in the case reported is important because it indicates that full action of the drug was not manifested for three hours after ingestion, despite definite evidence that absorption began early. The reason for the rapid onset within a few seconds of severe signs and symptoms is unexplained. Either the absorption rate was suddenly increased, which appears unlikely, or, after gradual absorption, the drug concentration finally reached the toxic level. Another possibility is that there was an undue accumulation of acetylcholine from the voluntary muscle activity of the brisk walk home and that the prostigmin, by preventing its destruction, allowed the acetylcholine to cause poisoning. This point is at present being investigated experimentally.

The shock picture resembled somewhat that seen in acetylcholine overdosage except that skeletal muscles were involved and there was no cutaneous vasodilatation. That such violent intestinal activity does not enter consciousness is of interest and it was some time before it became apparent that the several periodic exacerbations were initiated mainly by the intra-abdominal storm. It is conceivable that such marked overactivity of "cholinergic" nerves throughout the body produces sufficient acetylcholine (preserved by the esterase-inhibiting prostigmin) to circulate to other sites and set up a vicious circle, which persists for hours. Some evidence for this is seen in the fact that

## THE TREATMENT OF PELLAGRA

Despite the observation of Goldberger that pellagra could be prevented by means of an adequate diet, and his subsequent recommendations for the treatment of pellagra, there has continued to be a high mortality rate in the severe cases of endemic pellagra in the South. This high mortality rate in the hospitals (from 31 to 69 per cent), irrespective of treatment, seemed to many physicians, particularly in the South, to be inconsistent with the statement that pellagra is a dietary deficiency disease. Early in 1934 McLester published the opinion that the knowledge as to the cause and treatment of endemic pellagra was inadequate and pointed out that a high mortality rate still existed in spite of the treatment recommended by Goldberger. In 1935 Spies, working in Lakeside Hospital, Cleveland, by a more careful method of dietary control was able to reduce the death rate in Lakeside Hospital from 54 per cent to 6 per cent. These patients for the most part were heavy consumers of alcohol and as a result neglected their diet.

The successful form of treatment used by Spies included administration of a high caloric diet, also high in protein, large amounts of yeast, adequate rest, good nursing care and, in certain cases, intravenous injections of large doses of a potent liver extract. Simultaneous administration of as much as a quart of whisky a day (to patients accustomed to that amount) did not interfere with the effectiveness of the treatment.

Since pellagra occurring in the northern part of the United States is usually associated with chronic alcoholism and that of the South is not, it became imperative to learn as fully as possible whether or not the pellagra of the North and that of the South were essentially the same disease and whether the therapeutic methods previously and effectively applied in the North could be successfully used in the South. Consequently an expedition from the Medical Service of Lakeside Hospital and from the Department of Medicine of the University of Cincinnati joined forces with McLester in the Hillman Hospital, a county institution at Birmingham,

Ala., in order to carry out the study. Some of the results of this study have been reported recently in the *Southern Medical Journal*<sup>1</sup> and in *THE JOURNAL*.<sup>2</sup> They show beyond reasonable doubt that so-called alcoholic pellagra and endemic pellagra have the same clinical symptoms and similar lesions, and that they respond to the same methods of therapy—indeed, that they are the same syndrome. Musser has recently stated: "It is absolutely astounding that statements are made in which it is said that pellagra is rapidly disappearing from the country. Pellagra, according to United States Public Health Service statistics for 1930, caused more deaths than all the diseases listed as communicable except pneumonia, tuberculosis and influenza."

These studies, showing that the patient with severe pellagra, whether addicted to alcohol or not, can nearly always be successfully relieved of his disease, point definitely to the fact that pellagra is a disease associated with malnutrition.

## EXERCISE IN DIABETES

Along with diet and insulin, exercise is an accepted part of the present-day treatment of diabetes.<sup>1</sup> Knowledge of the mechanism of muscular work suggests the explanation of the ability of exercise to augment the blood sugar-lowering effect of insulin. The utilization of muscle glycogen during exercise results in a hypoglycemia which is effectively counteracted by the rapid hydrolysis of liver glycogen. Thus there is an accelerated catabolism of carbohydrate during exercise, and a working patient will require less insulin for the same amount of carbohydrate catabolized than does a resting patient. In certain conditions, however, exercise may bring about a marked increase in the blood sugar of the diabetic patient. This is seen particularly when the diabetic condition is severe and if several hours has elapsed since insulin and food were given. This relationship between the initial level of blood sugar and the effect of exercise on the diabetic patient has been pointed out by several investigators and carefully considered by Richardson.<sup>2</sup> However, the practical bearing of these observations on the use of exercise in the treatment of diabetes mellitus has been frequently overlooked. Additional emphasis is now derived from a recent investigation reported from the New England Deaconess Hospital.<sup>3</sup>

Young diabetic patients in good physical condition were subjected to two or three types of exercise: running at a definite rate, working on a rowing machine

grams of allantoin is added to 500 cc. of sterile water that has been heated to near boiling point. This makes a solution of 0.4 per cent. Heating is continued without boiling, until the crystals dissolve. Precautions are threefold. Asepsis must be guarded vigilantly, since the solution cannot be autoclaved. Chilling must be prevented lest the allantoin recrystallize. Finally, excessive sunlight will decimate the strength of the solution.

The mode of application is through packings and dressings. The wound is cleaned thoroughly with hydrogen peroxide followed by ether and is then bathed with sterile water. To secure general granulation growth, the wound is covered first with gauze that has been soaked with allantoin, then with a wet pack of allantoin laid on top of the gauze, and finally with a dry dressing. For deep wounds the packing is soaked in allantoin and inserted right into the wound at its base. For the allantoin to be most effective the dressings should be renewed before they become dry, since this acts only when it is in contact with the wound. No other chemical should be used during this treatment.

Since, as stated, the action of allantoin lasts only as long as the solution is in contact with the wound, it can therefore be easily controlled. Its effect is entirely local and overgrowth of granulation tissue may be readily checked. The speed with which the necrotic base is converted into a granulating area is remarkable. After the first week the wound assumes the appearance of a healthy granulating ulcer, and day by day new islands of granulation tissue can be seen springing up. Pain, which often accompanies these wounds and is a disabling factor, ceases almost immediately with the application of allantoin.

#### REPORT OF CASES

There follow herewith descriptions of three cases and their responses to allantoin:

CASE 1.—A woman, aged 50, weighing 250 pounds (113 Kg.), with irrelevant past history, struck her leg against a chair ten years ago and suffered an abrasion of the skin. The wound never healed and eventuated into an ulcer about 3.75 cm. in size. Despite various forms of treatment the ulcer remained open. Examination on the first visit revealed a deep irregular ulcer. The base was necrotic, the edges were indurated and the tissues surrounding the wound were inflamed. A Wassermann test and urinalysis were negative. Allantoin was used as described and after three weeks' treatment the wound decreased to about 1.75 cm. in size. The base is now clean, with healthy granulation present. At this writing the wound is still open and the treatment is being continued. There is every reason to believe that under this treatment the wound will close.

CASE 2.—A woman, aged 80, whose past history was negative, developed an ulcer in the popliteal space, nine years ago, which never healed. She had been treated at various hospitals. Skin grafts were performed, to no avail. Her chief complaints were pain and inability to walk. She disregarded the nonhealing of the ulcer, as she had thought it incurable. When first seen, there was a large, foul-smelling, indurated, infected ulcer involving the entire popliteal space. After the first application of allantoin the patient was relieved from pain. Under continuous treatment with allantoin over a period of two months the ulcer has decreased to one-half its size, and it is filled with bright red granulating areas. The patient, throughout the treatment, has been up and about.

CASE 3.—A woman, aged 65, employed as a cleaner, developed an ulcer ten years ago, following a bruise. She had used lotions and ointments with no improvement. The leg presented the typical picture of elephantiasis with a large irregular ulcer encircling it at the junction of its middle and lower thirds. A foul-smelling discharge was present. The base was necrotic. The patient complained of sharp, severe, excruciating pain in the leg, inability to walk and a continuous foul discharge.

Under treatment with allantoin for six weeks the ulcer on the outer aspect of the leg has fully granulated, the foul odor has disappeared, the discharge has diminished, healthy granulations are present throughout the remainder of the ulcer, the patient is free from pain, and she walks with great ease. In this case the surrounding skin became reddened. An ointment dressing was placed on the skin and the irritation subsided.

#### CONCLUSIONS

1. Allantoin, found in excretions of maggots and common to plants, can be prepared commercially.
  2. It is stable and nontoxic.
  3. It induces healing by stimulating healthy granulations and removing necrotic material.
  4. Treatment is painless, simple and inexpensive.
  5. Patients are ambulatory under this treatment.
  6. It acts locally as long as allantoin is in contact with the wound.
  7. Overgrowth of granulation tissue can be checked by discontinuing applications.
  8. Allantoin seems to have the same curative effect on chronic ulcers as the introduction of maggots, and it is less troublesome for the physician to administer and less disturbing to the patient than the use of insects.
- 130 Henry Street.

### Clinical Notes, Suggestions and New Instruments

#### MULTIPLE NEURITIS FROM THERAPY WITH HEMATOPORPHYRIN HYDROCHLORIDE

MELVIN WILFRED THORNER, M.D., PHILADELPHIA

This report of a case of multiple neuritis is of interest because it represents a danger in the use of hematoporphyrin hydrochloride (photodyn) in the treatment of psychotic depressions.

Huhnerfeld<sup>1</sup> found that injections of hematoporphyrin in animals increased their total motor activity. As a result of this experiment he used this agent in the treatment of psychotic depressions, with eleven improvements in thirteen cases. Since this report others have appeared, and Angus<sup>2</sup> has summarized these reports collectively and found that, of 113 depressions, fifty-seven were much benefited by this therapy. No satisfactory explanation of the mechanism by which this agent operates has been deduced from these investigations, and its use rests largely on an empirical basis.

In the time intervening between Huhnerfeld's report and the present, hematoporphyrin hydrochloride has come to be used extensively in the hands both of the specialist and of the general practitioner. This therapeutic enthusiasm has been heightened by the apparent absence of untoward effects from this therapy. That these may become recognized with the accruing of more experience is indicated by this report.

#### REPORT OF A CASE

A white woman, aged 36, married, in January 1936 complained of inability to concentrate and of a feeling of depression. The father, who died of pneumonia at the age of 70, had been a moody person who from time to time entered on grandiose business ventures, all of which were unsuccessful. There is no history of psychosis in the immediate or collateral lines. The family history is otherwise irrelevant.

Intellectual development was normal and the patient was graduated from high school at the age of 17. At 18 she suffered a short period of depression, followed by an excited period from which she recovered in a few weeks. She became secretary to an important executive at 20 and continued in this

### CANCER SOCIETY PROMOTES WOMEN'S FIELD ARMY

During the week of March 21 to March 27, women throughout the United States will have an opportunity to enlist in a new movement known as the Women's Field Army of the American Society for the Control of Cancer. The movement has received the endorsement of the Board of Trustees of the American Medical Association and is one to which physicians everywhere may lend their support. The object of the campaign is, of course, education of women regarding the nature of cancer, encouragement to periodic examination and enlistment of interest. Approximately 140,000 die each year in the United States from cancer. A considerable portion, perhaps even half, of these might have their lives prolonged if the condition came soon enough to the attention of a physician for suitable treatment. Since women suffer more from cancer than do men, and since the type of cancer that affects women, namely, cancer of the uterus and of the breast, is more certainly diagnosed in its early stages and more certainly treated than cancer as it affects men, this movement should have the definite effect of lowering the death rate from this disease. Women's clubs, the research workers throughout the nation, and many others are combining in this effort toward combating what is today the most feared of all disease. Yet the knowledge of it makes such fears unwarranted if intelligence is used in combating the disease. The Women's Field Army is a movement for extending education and, therefore, promoting intelligent action.

### TREATMENT OF STREPTOCOCCIC INFECTIONS WITH SULFANILAMIDE

Long and Bliss<sup>1</sup> have now supplemented their preliminary report in *THE JOURNAL*<sup>2</sup> on the use of sulfanilamide and its dye derivative, the disodium salt of 4'-sulfamidophenyl-2-azo-7-acetylamino-1-hydroxynaphthalene-3, 6-disulfonic acid (Prontosil) in the treatment of streptococcic infections by more extended publication in the *Archives of Surgery*. They were able to confirm in part the reports of European investigators regarding the efficacy of sulfanilamide<sup>3</sup> (para-aminobenzenesulfonamide) and its chemical derivatives in the treatment of beta-hemolytic streptococcic infections in mice. They report that mice thus treated have died of streptococcic infection as late as seventy-four days after the infection or sixty days after discontinuance of prontosil administration. The explanation for this occurrence is not clear; but since prontosil probably acts by inhibition of bacterial growth and therefore allows phagocytosis, discontinuance of the chemotherapy might allow any unkilld organisms to resume multiplication and invasion. These authors also report the results of treatment of seventy persons ill with infections due to beta-hemolytic streptococci. There

were only four deaths, and only one of these was considered to represent failure of the specific therapy. About forty-eight hours, they believe, is required before the maximum therapeutic effects can be obtained with sulfanilamide or its derivatives. The time of administration is therefore important. In severe infections in which the immediate prognosis is grave, either prontosil in 2.5 per cent solution or sulfanilamide in 0.8 per cent physiologic solution of sodium chloride parenterally is recommended. None of the toxic manifestations observed were severe. The question of late delayed toxic effects from the use of these compounds can be answered only when clinical experience with them becomes greater. It seems logical to believe, they state, that the prompt recognition of the nature of hemolytic streptococcic infection plus the adequate administration of the specific chemotherapeutic agents will greatly lessen mortality and duration of illness.

### COMPENSATION IN OCCUPATIONAL DISEASE

The problem of compensation for disease contracted by employees engaged in various types of occupations frequently arises. In the workmen's compensation act, according to a recent article,<sup>1</sup> an occupational disease is defined as "a disease peculiar to the occupation in which the employee was engaged and due to causes in excess of ordinary hazards of employment as such." Thus, the decision as to whether or not a disease is an occupational one and therefore one for which compensation may be claimed rests in particular cases on an interpretation of the phrases "peculiar to the occupation" and "in excess of ordinary hazards of employment." A recent court decision<sup>1</sup> by the Connecticut Supreme Court of Errors on a claim for compensation by an employee of a company engaged in the manufacture of women's dresses illustrates the importance of interpretation in this type of medicolegal case. The employee had contracted pulmonary tuberculosis because of conditions of employment and had been awarded compensation for disability by the commissioner. The trial court, however, sustained an appeal of the defendants and the plaintiff appealed, in turn, to the supreme court of errors. The ruling of the trial court was upheld by the higher court and compensation was denied on the ground that "to come within the definition, an occupational disease must be a disease which is a natural incident of a particular occupation, and must attach to that occupation a hazard which distinguishes it from the usual run of occupations and is in excess of that attending employment in general." The court ruled further that "it does not include a disease which results from the peculiar conditions surrounding the employment of the claimant in a kind of work which would not from its nature be more likely to cause it than would other kinds of employment carried on under the same conditions." In the present case "the plaintiff's disease resulted from the conditions of her particular employment in the factory of the defendants. Other trades carried on under those conditions would have been as likely to cause the disease as the manufacture of dresses."

3. Sulfanilamide is the nonproprietary term adopted by the Council on Pharmacy and Chemistry for para-aminobenzenesulfonamide. A report has not been issued yet by the Council on the acceptability of the preparation.

1. Court Decision on Public Health, *Pub. Health Rep.* 51: 1506 (Oct. 30) 1936.

unhurried tracheotomy was performed. The third and fourth tracheal rings were incised and a No. 4 tracheotomy tube was inserted as the bronchoscope was withdrawn. The child was returned to the ward in good condition and given continuous steam inhalations.

During the next four days a considerable amount of thick, membranous exudate was removed during suction of the trachea. Microscopically this was seen to be fibrinopurulent exudate. This membrane was found also on the epiglottis, aryepiglottic folds and arytenoids. The child swallowed well and painlessly the day after admission. Roentgenograms of the chest revealed normal lung fields.

The child had an uneventful convalescence. On the tenth day after tracheotomy the edema of the larynx and the membranous exudate had completely disappeared and the cannula was withdrawn. The wound edges were brought together with adhesive plaster. Three days later he was discharged with the wound completely closed, his voice strong and clear, and general health excellent.

#### COMMENT

Warnings should be issued to the public and to the venders as to the inherent dangers in the handling of "dry ice," and extreme care should be exercised to prevent children from getting hold of this "dry ice." The hazards of the practice of playfully "blowing off steam" should be stressed in the public school health class.

Fifth Avenue and One Hundredth Street.

#### COMMON ACNE AND INSULIN HYPOGLYCEMIA

JOSEPH WORTIS, M.D., NEW YORK

Research Fellow in Psychiatry at the Bellevue Psychiatric Hospital

A few months ago in the course of hypoglycemic insulin treatment of a psychotic boy according to Sakel's method,<sup>1</sup> I was impressed by the rapid disappearance of the patient's facial acne lesions soon after the treatment started. The youth, aged 17, according to his father had been troubled by occasional skin eruptions of moderate severity since puberty. His skin condition had, however, grown definitely worse about six months prior to his admission to the hospital, at about the time that the psychosis first developed, so that many of his complaints and delusions involved his skin condition, and much of his tenseness and restlessness found expression in the constant fingering of the lesions. The lesions themselves were distributed over the entire face—cheeks, chin and forehead—and were either small, superficial and pustular or more deeply seated and papular or nodular. His complexion was otherwise pasty and yellowish, and there were many acne scars and lacerations scattered between the lesions. The improvement began after the first day of treatment, after he had been given 10 units of insulin while fasting and allowed to remain hypoglycemic for four hours before being given lunch. On subsequent days the dose was increased by 5 or 10 units a day, and hypoglycemia was again sustained for several hours before the patient was allowed to eat. Within a few days practically all the fresh lesions had dried and disappeared, and only occasional new lesions took their place. The more deeply seated torpid nodules remained longer, and the scars remained longest of all. At the same time the patient's color was much improved, and his skin seemed smoother and fresher. This improvement was sustained throughout treatment, but it is noteworthy that (1) the improvement appeared long before shock doses were reached and (2) a relapse of the patient's skin condition occurred coincidentally with a relapse in the patient's mental state in the course of treatment. It is noteworthy too that the patient regained more than his 25 pounds (11.3 Kg.) of lost weight during the first two months of treatment.

In the second case, characterized mainly by seborrheic skin and deep nodular lesions, the improvement after insulin hypoglycemic treatment was equally marked. The patient was a schizophrenic youth with a less severe and more chronic acne.

Dr. Manfred Sakel and Dr. J. R. Ross gave the author permission to cite the cases observed at Harlem Valley State Hospital. From the Psychopathic Division of Bellevue Hospital and the Department of Psychiatry of New York University Medical College.

1. Wortis, Joseph: On the Response of Schizophrenic Subjects to Hypoglycemia Insulin Shock, *J. Nerv. & Ment. Dis.* 84:497 (Nov.) 1936.

In four additional cases that I have recently seen in the course of treatment by Dr. Manfred Sakel at Harlem Valley State Hospital at Wingdale, N. Y., there was an equally striking improvement after the first few days of treatment, with doses of insulin varying from 10 to 50 units and a hypoglycemic period of usually less than four hours' duration. In two of these cases—both in young women—the acne was of extreme severity and the improvement was abrupt and striking. These six cases comprise all patients with facial acne that were seen under treatment, so that in this small series, at least, all the cases were definitely benefited.

In the more marked hypoglycemic reactions the skin is probably benefited by the cutaneous hyperemia and profuse sweating that insulin coma provokes. The patient who is aroused from coma with a tube feeding has typically a flushed, moist skin and clear eyes. (One of my subjects said and looked as if he had had "a nice long workout on the golf course.") But in all the cases here reported, the improvement commenced with doses too small to provoke violent reactions or hypoglycemic coma. It is of some theoretical interest to note that acne lesions are rather common in young schizophrenic individuals. Schizophrenia is usually not associated with skin disorders and may occur in a person with a perfectly clear complexion, but it seemed significant that these six cases of acne of marked severity—at least three of them of extreme severity—were found in a group of less than thirty-five young schizophrenic patients.

It is possible that both schizophrenia and acne are associated with some common disturbance of carbohydrate metabolism, which is in turn benefited by protracted insulin hypoglycemia. It is also possible that the compensatory production of epinephrine which insulin hypoglycemia provokes may be another factor involved.

These observations are submitted to dermatologists for what they are worth. Hypoglycemic insulin shock treatment is not recommended as the treatment of choice for common acne. It is possible, however, that sustained hypoglycemia with small doses of insulin, under proper precautions, will prove serviceable.

60 Gramercy Park North.

#### GENERAL ANESTHESIA COMPLICATED BY CONVULSIONS

JOHN S. LUNDY, M.D., AND EDWARD B. TUOHY, M.D.  
ROCHESTER, MINN.

Convulsions occurring in a case in which a general anesthetic has been administered and while the patient is yet in a state of anesthesia is a situation that has occurred with a certain amount of frequency in recent years in this country. The condition was first reported in England in 1927, and most of the literature concerning it has appeared in British medical journals. However, attempts have been made to bring this problem to the attention of the medical profession of the United States. The problem is one that deserves more attention than it has received. The recent contribution of Tovell and Rosenow<sup>1</sup> would seem to point out possibilities that have not previously been suggested, and no doubt there may be other approaches that have not yet been made. In the meantime, however, it seems important to suggest to all those who directly or indirectly may be responsible for the administration of anesthetics that, when convulsions appear in the anesthetized patient, an anticonvulsant be given; for example, any one of the soluble barbiturates should be administered intravenously. The probabilities are that such treatment will control the convulsions until the patient has recovered from the general anesthesia. If the anesthesia has been a contributing cause of the convulsions, the convulsions should cease, and if the operation has removed a focus of infection, which may have contributed to the production of convulsions, it should be possible to control the convulsions as the illness subsides in the ensuing hours or even days. This has been possible in cases of tetanus, in which the administration of tribrom-ethanol by rectum has been resorted to with considerable satisfaction, and the probabilities are that this

**Branch Society Meetings.**—Dr. Owen H. Wangenstein, Minneapolis, discussed "Studies in the Etiology of Acute Appendicitis" before the Aux Plaines Branch of the Chicago Medical Society, February 26.—The North Shore Branch was addressed March 2 by Drs. Walter C. Alvarez, Rochester, Minn., on "Helpful Hints in the Treatment of Gastro-Intestinal Diseases" and Benjamin Goldberg, on "Bronchiectasis."—At a meeting of the Englewood Branch, March 2, Dr. Arthur E. Hertzler, professor of surgery, University of Kansas School of Medicine, Kansas City, discussed "Indications for Surgical Treatment in Toxic and Nontoxic Goiter," and Dr. Leroy H. Sloan, "Medical Management of Toxic and Nontoxic Goiter."—Dr. Fred M. Smith, professor and head of the department of theory and practice of medicine, State University of Iowa College of Medicine, Iowa City, spoke on left ventricular failure at a meeting of the North Side Branch, March 4.—Dr. Edward D. Churchill, John Homans professor of surgery, Harvard University Medical School, Boston, discussed "Hyperparathyroidism" before the Evanston Branch, March 4, and Dr. Richard H. Young, "The Anemias—A Physiologic Approach."

## IOWA

**Cancer Data to Be Recorded.**—The Linn County Medical Society adopted a plan, February 11, to keep complete cancer records, including data on heredity, on all cancer patients treated by its members. Dr. Frederick W. Mulsow, Cedar Rapids, was appointed official custodian of the county's records. He is also the physician-chairman of an experiment in lay and professional education in cancer, which is being promoted by the cancer committee of the Iowa State Medical Society in cooperation with the American Society for the Control of Cancer and its Women's Field Army.

**Society News.**—Dr. William Weston, Columbia, S. C., will discuss "Problems in American Nutrition" before the Linn County Medical Society, Cedar Rapids, April 8, and Dr. John J. Terrall will read a paper entitled "Medical Advertising."—At a joint meeting of the Pottawattamie County Medical Society and Council Bluffs City Dental Society, Council Bluffs, February 22, H. Berner, D.D.S., Council Bluffs, discussed pyorrhea, and Max Dunshee, D.D.S., Council Bluffs, Vincent's infection in the mouth.—Dr. Rosco G. Leland, Director, Bureau of Medical Economics, American Medical Association, Chicago, addressed a public meeting in Des Moines, March 9, sponsored by the educational committee of the Polk County Medical Society. He discussed "Confidence in Your Physician."

## KENTUCKY

**Centennial Celebration at University of Louisville.**—The University of Louisville School of Medicine will celebrate the one hundredth anniversary of its founding with a four day program March 31-April 3. Guest speakers announced in the program are:

Dr. Mont R. Reid, Cincinnati, Aneurysms.  
Dr. Roy Wesley Scott, Cleveland, Latent Syphilis as a Cause of Heart Disease.  
Dr. William D. Haggard, Nashville, Tenn., Prevention and Cure of Goiter.  
Dr. Arthur T. McCormack, Louisville, state health officer, The Recent Flood in Kentucky from the Standpoint of Public Health.  
Chauncey D. Leake, Ph.D., San Francisco, Medical Frontier a Century Ago.  
Dr. Marion A. Blankenhorn, Cincinnati, Pellagra: A Comparison of Endemic Pellagra with So-Called Alcoholic Pseudopellagra.  
Dr. Willis D. Gatch, Indianapolis, Surgical Prognosis.  
Dr. Hugh J. Morgan, Nashville, Tenn., Problems in Experimental Syphilis.  
Dr. Albert Graeme Mitchell, Cincinnati, Endocrinology in Childhood.  
Dr. Lawrason Brown and Homer L. Sampson, B.S., Saranac Lake, N. Y., The Fate of the Good Chronic "T. B."  
Dr. Quitman U. Newell, St. Louis, Cancer of the Uterus.  
Dr. Ernest W. Goodpasture, Nashville, Pathogenesis of Infectious Disease.  
Dr. Alfred N. Richards, Philadelphia, Function of the Kidney.

Friday afternoon the guests will inspect the medical school, where the departments will have special exhibits. The library will illustrate the history of teaching at the university, the scientific work accomplished there and high lights of advances in various fields. Friday evening there will be an alumni banquet at which Dr. Irvin Abell, clinical professor of surgery, and Raymond A. Kent, Ph.D., president of the university, will speak. Saturday morning a new dispensary will be dedicated at the Louisville City Hospital, which is affiliated with the medical school. The celebration will end with a public meeting Saturday evening at the Louisville Memorial Auditorium, at which Dr. Simon Flexner, director emeritus of the Rockefeller Institute for Medical Research, New York, will speak on "A Half Century of American Medicine." Dr. Flexner is a native of Louisville and a graduate of the school of medicine, class of 1889. The original school of medicine founded in 1837 was known as the Louisville Institute of Medicine. The name was

changed in 1846 to University of Louisville Medical Department. In 1907 the Kentucky University Medical Department and in 1908 the Kentucky School of Medicine and the Louisville and Hospital Medical College merged with the school and in 1922 it received its present title. Dr. John Walker Moore has been dean since 1929.

## MARYLAND

**The DeLamar Lectures.**—Dr. Thorvald Madsen, director of the State Serum Institute, Copenhagen, Denmark, delivered the fifth DeLamar Lecture of the current series at the School of Hygiene and Public Health of Johns Hopkins University, Baltimore, February 23, on "Control of Syphilis in Denmark." Previous lectures in the series were:

Dr. Frank G. Boudreau, formerly official in charge of liaison, health administration, Health Section of the League of Nations, and recently appointed medical director of the Milbank Fund, New York, November 10, The Future of International Cooperation in Hygiene.  
Dr. George C. Dunham, major, medical corps, U. S. Army, November 24, Progress of Public Health Work in the Philippine Islands.  
Dr. Richard E. Shope, department of animal and plant pathology, Rockefeller Institute for Medical Research, December 1, Recent Studies on the Etiology of Influenza.  
Dr. Edward S. Godfrey Jr., Albany, state health commissioner of New York, January 12, Epidemiology and Public Health Administration.

Speakers to come are Frank W. Notestein, Ph.D., of the School of Public and International Affairs of Princeton University, and Dr. Simeon Burt Wolbach, Shattuck professor of pathologic anatomy, Harvard University Medical School.

## MASSACHUSETTS

**Personal.**—Dr. Alphonso V. Bowker, Athol, observed his eightieth birthday, January 17.—Dr. Eoline B. Church Dubois, Springfield, has been appointed permanent medical inspector for the local school department.

**Society News.**—The first issue of the *Worcester Medical News*, official organ of the Worcester District Medical Society, recently appeared.—Dr. Warren F. Draper, U. S. Public Health Service, discussed "The Federal Program of Syphilis Control" before the Massachusetts Public Health Association in Boston, January 28.—At a meeting of the Harvard Medical Society in Boston, January 26, Dr. Louis Hamman, Baltimore, spoke on "Spontaneous Interstitial Emphysema of the Lungs."—Dr. Clarence A. Bonner, Danvers, addressed the Pentucket Association of Physicians, February 11, in Haverhill, on "Some of the Preventive Aspects of the Mental Health Problem."—Dr. Ernest M. Morris, Fall River, was elected president of the Massachusetts Public Health Association, January 28.—Dr. Morris Fishbein, Editor of THE JOURNAL, addressed the Boston University Medical Society, February 28, on "Medicine and the Changing Social Order."

## MICHIGAN

**Mass Meeting on Cancer.**—Dr. William A. O'Brien, associate professor of pathology and preventive medicine and public health, University of Minnesota Medical School, Minneapolis, will address a mass meeting of women, March 24, in the Statler Hotel, Detroit. His subject will be "Woman's Contribution to the Cancer Problem." This meeting is a part of the program of the Women's Field Army of the American Society for the Control of Cancer and is sponsored by the woman's auxiliary of the Wayne County Medical Society. According to *Detroit Medical News*, Governor Murphy has been requested to proclaim the week of March 21 "Fight Cancer Week" throughout the state and Mayor Frank Couzens has been asked to designate March 25 as "Fight Cancer Day" in Detroit.

## MINNESOTA

**Personal.**—Dr. Charles A. Williams, Pipestone, was recently appointed physician at the Pipestone Indian School.—Dr. Morris H. Nathanson, assistant professor of medicine, University of Minnesota Medical School, Minneapolis, has been appointed associate professor of medicine at the University of Southern California Medical School, Los Angeles.—Dr. Leo M. Maguire has been appointed chief medical officer in charge of the veterans' hospital at Fort Snelling.

**Course for Hospital Librarians.**—The division of library instruction of the University of Minnesota will offer a training course for hospital librarians, March 30-June 12, in response to a demand from workers in hospital libraries, the medical and nursing staffs of hospitals and the Minnesota Board of Control. Miss Perrie Jones, librarian of the St. Paul Public Library, who has just retired from her position as institution librarian of the state board of control, will be in general charge of the course. Medical and library experts of the university and

perature elevation by means of the blanket than by other measures. Contrasted with the hot water baths (temperatures from 101 to 110 F.) the time required appears to be about three times as long. This lag in raising the temperature is regarded as undesirable when one wishes to elevate the temperature to a high level and maintain it for a long period of hours.

Patients undergoing treatment complained about the weight of the blanket. It caused them great inconvenience in their respiratory movements. Respiration became embarrassed anyway, as a result of the temperature elevation per se. The mechanical factor of a heavy blanket markedly increases the difficulty. The weight of the blanket also presents a special problem in the treatment of persons in whom acutely involved joints are especially sensitive to pressure.

The treatment of patients suffering from diseases of the skin by the electric blanket is bound to be most difficult. They complain of severe itching.

Profuse perspiration during the prolonged heating causes the blanket to become saturated. The rubber sheeting supplied appears to be ineffective. Because of the moisture the patient may then complain of feeling cold and uncomfortable even though the temperature of the blanket is considerably elevated.

Although the blanket may raise body temperature, the dangers inherent in the elevation of temperature to a high level and maintaining it precludes the use of electric blankets and other apparatus for raising body temperature as an office procedure. Because of the dangers involved, specialized training of the personnel administering the treatment becomes of major importance.

In view of the objections raised to the therapeutic application of this apparatus, the Council on Physical Therapy voted not to include the Conducto-Therm in its list of accepted apparatus.

#### HOME DIATHERMY MACHINE NOT ACCEPTABLE

Manufacturer: Home Diathermy Company, 1776 Broadway, New York.

The Home Diathermy Machine is a small unit which is advertised principally by radio (broadcasts are given in English, Italian and German) and is sold directly to the public by lay salesmen, provided with pamphlets and testimonials of lay users. The instruction for its use is given by the salesmen. The machine is portable and is estimated to weigh about 20 pounds. There are no visible meters, but there are two adjustable spark gaps on the control panels.

A copy of the advertising matter which has been referred to the Council contains such statements as "Health & Vigor are now yours through the use of a portable and simplified HOME DIATHERMY," and "You who suffer from Asthma can now find in Diathermy, the modern method of eliminating that heaviness in the chest, the susceptibility to colds, and that choking and gasping feeling." One reason given in support is "Diathermy and Modern Science is the logical answer to your problems! Years of scientific research have proven the fact that Life and Electricity are closely related. All motor activity in cell life is dependent upon energy or electrical heat. . . . DIATHERMY takes the first place in the electro-therapy art."

One part of the advertisement reads "Some of the many ailments where pain and agony is eliminated through the use of DIATHERMY. . . . Inflammatory and toxic states such as: Arthritis, rheumatism, neuritis, bursitis, lumbago, neuralgia, pneumonia, sciatica, bronchitis, asthma, high or low blood pressure."

Further on it is stated "Our representative will be pleased to call at your home, and give you a free demonstration of the Home Diathermy."

In the opinion of the Council on Physical Therapy, the Home Diathermy Company is practicing methods that are detrimental to rational therapeutics. The use of promotional radio advertising by those unqualified to practice medicine constitutes an appeal to the public with arguments which are unscientific and may harmfully enhance a feeling of false security on the part of the public.

In view of the foregoing, the Council voted not to include the Home Diathermy Machine in its list of accepted devices.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.  
PAUL NICHOLAS LEECH, Secretary.

#### MERCURIC BINIODIDE OIL SOLUTION IN AMPULES, H. W. & D., OMITTED FROM N. N. R.

This has been accepted for many years and is described in New and Nonofficial Remedies, 1936, under Red Mercuric Iodide-N. F. Its acceptance expired with the close of 1936. In its reply to the Council's request for material on which to base reacceptance, the firm of Hynson, Westcott & Dunning replied that it felt the product might well be omitted since, although still used to some extent, it is not in general demand. The product was formerly official but has been omitted from the U. S. P. XI and the Council believes that it would be a step backward to encourage its therapeutic use. The Council therefore voted to omit Mercuric Biniodide Oil Solution in Ampules, H. W. & D., from New and Nonofficial Remedies, together with the description of Red Mercuric Iodide-N. F.

#### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**PROTAMINE ZINC INSULIN** (See THE JOURNAL, Feb. 20, 1937, page 640).

**Protamine Zinc Insulin.**—Mulford.—A brand of protamine zinc insulin.

Manufactured by Sharp & Dohme, Inc., Philadelphia, under license from the governors of the University of Toronto.

**Protamine Zinc Insulin.**—Mulford, 10 cc.: Each cubic centimeter contains 40 units of insulin together with protamine and approximately 0.08 mg. of zinc.

**DIPHTHERIA TOXIN FOR THE SCHICK TEST** (See New and Nonofficial Remedies, 1936, p. 409).

The Gilliland Laboratories, Inc., Marietta, Pa.

**Diphtheria Schick Test Toxin, Diluted Ready for Administration.**—Gilliland.—Also marketed in packages containing sufficient material for 100 tests. As a means of control, the Schick Test Control representing diluted diphtheria toxin heated sufficiently to destroy the specific exotoxins is supplied in packages containing sufficient material for ten, twenty-five, fifty and 100 control tests.

**DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)** (See New and Nonofficial Remedies, 1936, p. 393).

The Gilliland Laboratories, Inc., Marietta, Pa.

**Diphtheria Toxoid, Alum Precipitated (Refined).**—Also marketed in packages of one 0.5 cc. vial (one immunization); ten 0.5 cc. vials (ten immunizations); one 5 cc. vial (ten immunizations).

**CALCIUM GLUCONATE** (See New and Nonofficial Remedies, 1936, p. 146).

**Calcium Gluconate-Abbott.**—A brand of calcium gluconate-U. S. P.

Manufactured by the Abbott Laboratories, North Chicago, Illinois. No U. S. patent or trademark.

**Sterile Ampoule Calcium Gluconate, 10%-Abbott:** Each ampoule contains 10 cc. of a 10 per cent stabilized supersaturated solution of calcium gluconate-Abbott.

**SODIUM AMYTAL** (See New and Nonofficial Remedies, 1936, p. 114).

The following dosage form has been accepted:

*Suppositories Sodium Amytal, 3 grains.*

**Dr. Foshay Appointed Professor of Bacteriology.**—Dr. Lee Foshay, associate professor of experimental bacteriology at the University of Cincinnati College of Medicine, has been made professor of bacteriology and hygiene to succeed the late Dr. William B. Wherry. Dr. Foshay is a graduate of the University of Pennsylvania School of Medicine, 1920. He served an internship at the Pennsylvania Hospital, Philadelphia, and a residency at the Lakeside Hospitals, Cleveland, and later was a Crile research fellow at Western Reserve University. In 1926 he was appointed assistant professor of medicine at Cincinnati and later was assistant professor of medicine at the State University of Iowa College of Medicine for a year. He then returned to Cincinnati as research fellow at Christ Hospital Institute for Medical Research and in 1932 again joined the faculty of the University of Cincinnati.

## OKLAHOMA

**Special Meetings.**—The Muskogee Academy of Medicine presented its fifth annual two-day conference February 18-19. The guest speakers were Drs. Paul S. Carley of the U. S. Public Health Service, who lectured on syphilology; Harry Wilkins, Oklahoma City, surgery of the brain; Henry M. Winans, Dallas, Texas, internal medicine; Edwin C. Hamblen, Durham, N. C., obstetrics and gynecology; Lee Wallace Dean, St. Louis, otolaryngology, and Alfred I. Folsom, Dallas, urology. —Three members of the faculty of St. Louis University School of Medicine conducted an all day clinic in Okmulgee, February 1, under the auspices of the medical societies of Okmulgee, Okfuskee, Tulsa and Muskogee counties. The speakers were Drs. Edward Lee Dorsett, on obstetrics and gynecology; Marion A. Webb, otolaryngology, and William K. McIntyre, surgery.

## OREGON

**Graduate Course in Portland.**—The second annual graduate course in ophthalmology and otolaryngology sponsored by the University of Oregon Medical School and the Oregon Academy of Ophthalmology and Oto-Laryngology will be held in Portland during the week of April 5. Dr. Cecil S. O'Brien, professor of ophthalmology, State University of Iowa College of Medicine, Iowa City, will present the course in ophthalmology and Dr. William J. McNally, demonstrator in otolaryngology, McGill University Faculty of Medicine, Montreal, the course in otolaryngology. Further information can be obtained from Dr. Augustus B. Dykman, Medical-Dental Building, Portland.

## PENNSYLVANIA

**Society News.**—Drs. John A. Daugherty, Walter J. Connor, Lillian E. Shaw and Oscar Benjamin Millard, Harrisburg, presented a symposium on pneumonia at the meeting of the Dauphin County Medical Society, Harrisburg, March 2. —Dr. Thomas Klein, Philadelphia, addressed the Harrisburg Academy of Medicine, March 16, on "Bedside Recognition of Cardiac Irregularities and Cardiac Decompensation." —Dr. William Wayne Babcock, Philadelphia, addressed the Northampton County Medical Society, Bethlehem, February 19, on "The Diagnosis and Management of Malignancy of the Intestinal Tract." —Dr. Hobart A. Reimann, Philadelphia, was the guest speaker at the meeting of the Cambria County Medical Society, Johnstown, February 11, on pneumonias. —Dr. Hugh M. Hart, New Wilmington, addressed the Lawrence County Medical Society, New Castle, February 4, on "Intermittent Hydrarthrititis." —Drs. Russell E. Sangston and Holbert J. Nixon addressed the Fayette County Medical Society, Uniontown, March 4, on "Treatment of Pneumonia in Children" and "Clinical Aspects of Influenza" respectively.

## Philadelphia

**Competition for the Alvarenga Prize.**—The College of Physicians of Philadelphia announces its annual competition for the Alvarenga Prize, amounting this year to \$200, for the best essay submitted on any branch of medicine. Essays must be original, unpublished contributions, typewritten in standard English or, if in another language, must be accompanied by a good translation in English. The original contribution must be appropriately correlated with the pertinent scientific literature. Essays must be sent without signature but must be plainly marked with a motto and accompanied by a sealed envelop bearing on the outside the motto of the paper and inside the name and address of the author. They must be received by the college before May 1. The successful essay will remain the possession of the college, but at any time following the award the author may at his discretion arrange for publication in an appropriate place. Other essays will be returned, if requested, as soon as the selection has been made.

**Second Annual Postgraduate Institute.**—Fifty-five Philadelphia physicians will take part in the second annual Postgraduate Institute to be presented by the Philadelphia County Medical Society, April 12-16, at the Bellevue-Stratford Hotel. The subject of this year's institute is "Diseases of the Chest and Upper Respiratory Tract." On the first day there will be a luncheon at which Dr. Francis Ashley Faught, president of the society, will preside and the speakers will be Mayor S. Davis Wilson, Dr. William C. Hunsicker, director of the city health department, and Dr. Donald Guthrie, Sayre, chairman of the committee on postgraduate teaching of the Medical Society of the State of Pennsylvania. At a dinner Wednesday evening the guests will be Mayor Wilson, Dr. Frederick J. Bishop, Scranton, president-elect of the Medical Society of the State of Pennsylvania, and Dr. John Shelton Horsley, Richmond, Va. At the regular meeting of the county society following the dinner Dr. Horsley will deliver the annual J. Chalmers Da Costa Oration on "Peritonitis" and the Strittmatter Award will be made. Dr. Rufus S. Reeves is chairman of the committee in charge of the institute.

## SOUTH CAROLINA

**Syphilis Control Program.**—At a meeting of representatives of the state board of health and the South Carolina Medical Association, called by Dr. James A. Hayne, state health officer, in Columbia, January 14, plans were adopted for a syphilis control program to be conducted with social security funds. It was proposed that a permanent central committee be appointed by the state medical association and local committees of physicians in each county. A statewide survey to determine the incidence of syphilis is to be made through various institutions and groups and private physicians. It was agreed that the state should furnish free certain specified drugs for treatment to both indigents and paying patients. Plans were also made for reporting of cases by physicians and for training of physicians. In a discussion of diagnostic clinics it was suggested that operations of such clinics be limited to the securing of blood for serologic testing and serum for dark field examinations of indigent cases or others referred by practicing physicians. Dr. Sedgwick Simons, Columbia, of the staff of the state board of health, has been placed in charge of the syphilis control program.

## UTAH

**Annual Registration Due April 1.**—All practitioners of medicine and surgery licensed to practice in Utah are required to register annually on or before April 1, with the Department of Registration, and to pay a fee of \$3. If a licentiate fails to reregister within from ninety days to six months after April 1, his license can be revoked, and, if revoked, it will be reinstated thereafter only on his paying the delinquent registration fees and an additional year's fee as a penalty.

## VERMONT

**Society News.**—Drs. Paul D. Clark, Charles K. Johnson and Herbert A. Durfee of the department of maternal and child welfare of the state board of health addressed the North-eastern Counties Medical Society at Lyndonville, February 25. Dr. Joseph S. Barr, Boston, addressed this society recently on "Orthopedic Conditions of the Knee." —Dr. Richard B. Cattell, Boston, spoke on "Lesions of the Colon and Rectum" before the Rutland County Medical Society, January 20. —Dr. Soma Weiss, Boston, addressed the Osler Society of the University of Vermont College of Medicine, Burlington, February 26, on "The Significance of the Relationship Between the Sympathetic Nervous System and the Cardiovascular System in Man." Dr. Henry L. Bockus, Philadelphia, spoke, February 15, on "Regional Ileitis, Ileocolitis and Chronic Granulomas of the Intestinal Tract." —Dr. Herbert M. Elder, Montreal, Que., addressed the Franklin County Medical Society in January on "Injection Treatment of Varicose Veins." —Dr. Howard M. Clute, Boston, was the speaker at the winter meeting of the Chittenden County Medical Society on "Clinical Diagnosis of Jaundice."

## VIRGINIA

**McGuire Lectures and Graduate Clinics.**—The annual Stuart McGuire Lectures and the graduate clinics of the Medical College of Virginia, Richmond, will be held March 24-25. Dr. Joseph Earle Moore, Baltimore, will deliver the lectures in the evenings, on "Diagnosis of Syphilis by the General Practitioner" and "Management of the Wassermann-Fast Patient." The clinics will be given during the days by the college faculty and the following guests: Drs. Dudley C. Smith, Charlottesville, Otis L. Anderson of the U. S. Public Health Service and Lonsdale J. Roper of the state health department.

and stair climbing. The blood sugar was determined on samples of blood collected before each exercise period and at frequent intervals during the period, which was from one to two hours in length. The results uniformly indicate that, in the fasting patient with severe or moderately severe diabetes who has not received insulin for several hours, the immediate effect of exercise may be an elevation of the blood sugar level. Blood sugar values of 480 mg. per hundred cubic centimeters could be raised to 560 mg. in individuals not receiving insulin seven hours prior to running at a moderate rate for five minutes. This observation was typical for five diabetic patients studied under similar conditions. The results are probably related to the inability of contracting muscle of the completely diabetic organism to utilize dextrose to obtain extra energy. Whatever the explanation of these observations may be, their practical application to the treatment of diabetes is evident. They emphasize again the value of adequate control of the diabetic condition. Since the introduction of insulin, the diabetic patient has been able to lead a fairly normal life with an average amount of activity. If the diabetic condition is imperfectly controlled and if the body has not been supplied with adequate insulin, however, exercise, instead of being beneficial, may actually increase the hyperglycemia and the glycosuria. For exercise to exert its maximum benefit, sufficient insulin should be available in the body at the time of exercise.

The results of these studies should be taken into consideration when one is prescribing exercise in the treatment of the diabetic condition. From a practical point of view the logical sequence for the diabetic patient, after arising in the morning, would seem to be insulin, exercise and breakfast rather than exercise, insulin and breakfast. The exercise should be mild enough so that undue fatigue is not produced. It seems needless to point out the further advantage of two, three or more additional periods of exercise during the day.

#### RATING COMMUNITY MILK SUPPLIES

The United States Public Health Service has recently published the seventh annual rating of the compliance of market milk supplies in urban communities with the Standard Milk Ordinance and Code.<sup>1</sup> The ordinance and code were published by the service as a guide and stimulus for the improvement of milk supplies through local ordinances modeled after the standard ordinance. The ratings are made annually by state milk sanitation authorities, in accordance with the Public Health Service rating method, based on grade A pasteurized milk and grade A raw milk requirements of the Public Health Service milk ordinance and code. In order to qualify, a community must have ratings of 90 or better for both raw and pasteurized milk, unless only raw

or only pasteurized milk is sold, in which case the rating for that class of milk must be over 90. Ratings must be made at least every two years; state milk sanitation standards will be checked from time to time by surprise ratings made by the United States Public Health Service. On the basis of these surprise check-ups, ratings may be discounted where state authorities are rating more than 5 per cent too high. It is urged in the report that communities bring their milk ordinances up to date at least every five years.

The importance of milk sanitation has been dramatized in the flood experiences of recent weeks, but danger from unsafe milk may be present in communities not stricken by disaster. Epidemics traced to raw milk are reported every year. One of the latest, in Owego, N. Y., in December 1936, involved 500 cases of scarlet fever traced to raw milk from one cow. As a result, the town has passed an ordinance requiring the pasteurization of all milk sold there.<sup>2</sup> In connection with ratings of market milk, while raw milk is rated, repeated warnings are given that no milk should be used in the home unless pasteurized. Home pasteurization is advised where only raw milk is purchasable; the technic advised is to heat the milk in an aluminum vessel on a hot flame to 155 F., with constant stirrings, and then to set the vessel in cold water and stir continuously until cool.<sup>3</sup>

The published ratings are significant. In communities in which all market milk is pasteurized, only four communities in two states have achieved a rating of 90 or more. Among communities in which some but not all market milk is pasteurized, eighty-one in nineteen states have achieved a rating of 90 or more both for raw milk and for pasteurized milk. Significant of what may be accomplished in a brief period is the change from a pasteurized milk rating of 59 per cent in Chicago in the spring of 1935 to a pasteurized milk rating of 97 per cent in January 1937. Communities in which only raw milk is sold and which rate 90 or above number only fifty in nine states. While the service emphasizes that the ratings published are only those which are available and not over 2 years old, and that it is not intended to convey the idea that no other communities are eligible for rating, the indications are sufficient to point the need for more attention to quality of milk, and especially to pasteurization requirements. Even certified milk, the safest of raw milks, is still safer when pasteurized, as its producers have recognized.<sup>3</sup> The milk industry has always been keenly interested in improving the quality of milk, as have health officials. Advice to drink more milk is futile, if not harmful, unless the milk available is clean and pasteurized and therefore free from dangerous possibilities of transmitting infectious disease.

1. Report on Market Milk Supplies of Urban Communities, Pub. Health Rep. 52:130 (Jan. 29) 1937.

2. Scarlet Fever Outbreak Traced to the Use of Raw Milk, Pub. Health Rep. 52:113 (Jan. 22) 1937.

3. Pasteurization of Certified Milk, editorial, J. A. M. A. 105:601 (Aug. 24) 1935.

## CANADA

**Dr. Boyd Appointed Professor at Toronto.**—Dr. William Boyd, professor of pathology, University of Manitoba Faculty of Medicine, Winnipeg, has been appointed professor of pathology at the University of Toronto Faculty of Medicine, to succeed the late Dr. Oskar Klotz. Dr. Boyd was graduated from the University of Edinburgh, Scotland, in 1911 and has been at the University of Manitoba since 1915. He has been pathologist to the Winnipeg General Hospital since 1918. In 1934 he was president of the American Association of Pathologists and Bacteriologists. During the World War he served with the British Army Medical Corps. He is 51 years old.

**Cameron Prize Awarded to Dr. Collip.**—The Cameron Prize of the University of Edinburgh, Scotland, has been awarded for 1937 to Dr. James B. Collip, professor and head of the department of biochemistry, McGill University Faculty of Medicine, Montreal. The prize is given annually to "a person who, in the course of the five years immediately preceding, has made any highly important and valuable addition to practical therapeutics." According to the *Lancet*, Dr. Collip received the award in recognition of his many contributions to endocrine therapy and in particular of his work on the parathyroid gland. Dr. Collip, who is 44 years old, is a native of Ontario. He received the degree of doctor of philosophy at the University of Toronto in 1916 and doctor of medicine at the University of Alberta in 1926. He was professor of biochemistry at Alberta for several years and went to McGill in 1928. The prize is about \$1,000.

## FOREIGN

**Congress on Therapeutics.**—The first International Congress of the Therapeutic Union will be held in Bern, Switzerland, May 19-22. Among speakers listed on the preliminary program are Drs. August Rollier, Leysin, Switzerland; Wolfgang Heubner, Berlin; Hyman I. Goldstein, Camden, N. J.; Theodor Rudolf Naegeli, Bonn, and James A. Gunn, Oxford. Those who wish to present papers are asked to communicate with the general secretary, Dr. Toni Gordonoff, Monbijoustrasse 97, Bern.

## Government Services

## Vacancies in Medical Corps of Navy

An examination for commissions and internships in the Medical Corps of the U. S. Navy will be held beginning May 10 in all naval hospitals and at the Naval Medical School, Washington, D. C. There are about fifty vacancies. Candidates for admission must be between the ages of 21 and 32 at the time of appointment, graduates of or senior medical students in class A medical schools. For further information write the Surgeon General, U. S. Navy, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

## Changes in Public Health Service

Passed Asst. Surg. William H. Meyer, relieved at Honolulu, and directed to proceed to marine hospital, Stapleton, N. Y.  
Dr. Harold R. Sandstead, appointed and commissioned as assistant surgeon in the regular corps, marine hospital, Cleveland.  
Dr. James F. Lane, appointed and commissioned as assistant surgeon in the regular corps, marine hospital, Stapleton.  
Dr. Joseph B. Pomerance, appointed and commissioned as assistant surgeon in the reserve corps for active duty, marine hospital, Cleveland.  
Dr. Laurence John Hakala, appointed and commissioned as assistant surgeon in reserve corps, U. S. Public Health Service Dispensary, Washington, D. C.  
Dr. Samuel Milton Dupertuis, appointed and commissioned as passed assistant surgeon in regular corps, marine hospital, Stapleton.  
Dr. Alfred J. Aselmeyer, promoted and commissioned as surgeon in regular corps.  
Dr. Thomas A. Hathcock Jr., commissioned as assistant surgeon in the reserve corps for active duty at the U. S. Marine Hospital, Baltimore.

## Annual Report on the Health of the U. S. Army

Automobile accidents again led the list of causes of death in the U. S. Army, according to the report of the surgeon general for the calendar year 1935. Sixty-six fatalities were recorded as compared with sixty in 1934. To this cause eighty deaths were ascribed in 1933, seventy-three in 1932 and ninety-two in 1931. Of the total, twenty-six deaths were attributed to collisions; in twelve cases the cause was "struck by vehicle"; in eleven "car overturned," and eight "crashed into objects off

road." There were 1,317 admissions from automobile injuries with a rate of 9 per thousand, as against 1,418 with a rate of 11 per thousand in 1934. Suicides and airplane accidents occupied second and third places in the list of causes of death with totals of fifty-five and forty-three respectively. These compared with respective totals of fifty-two and fifty-six in 1934.

The first disease to appear on the list, disease of the coronary arteries and angina pectoris, stands fourth in the list of causes of death, with forty fatalities. Tuberculosis is fifth with thirty-two deaths, and pneumonia is sixth with thirty-one. In 1934 pneumonia was first disease on the list, occupying fourth position among causes of death with thirty-four deaths.

The leading causes of admission in 1935 were athletic exercises (4,046), bronchitis (3,745) and gonorrhea (3,172). In 1934 bronchitis occupied first place and athletic exercises second. Influenza rose from ninth place with 1,874 cases to fourth place with 2,837 cases.

There were 547 deaths among army personnel in 1935, giving a rate of 3.8 per thousand, compared with 4 in 1934; 298 died from disease and 249 from external causes as compared with 275 and 268 respectively in 1934. There were 1,387,945 days lost in the hospital during the year by the military personnel as compared with 1,363,591 days for the previous year. Exclusive of the military personnel, which includes Veterans' Administration, Soldiers' Home, National Guard Officers' Reserve Corps, Reserve Officers' Training Corps, Citizens' Military Training Camps, Civilian Conservation Corps, and other civilians receiving treatment, there were 1,831,659 days in the hospital. The outpatients for the year numbered 1,439,749, with 2,566,719 treatments. There were 534,410 physical examinations and 483,860 vaccinations. The daily average of patients in the hospital was 8,820.8.

By legislative action the average daily strength of the army was increased during the year to 142,568, as compared with 134,716 in 1934. There were 66,086 vacancies during 1935 as compared with an earlier total of 60,741; of these 36,342 or 55 per cent were filled by original enlistments. The average officer strength for the year was 11,660, including 842 warrant officers. During the year seventy-eight officers, sixteen nurses and 1,999 enlisted men were separated from the service on account of disability as compared with 130 officers, eight nurses and 2,165 enlisted men for the previous year. The discharge rate for the whole army was 14.6 per thousand for 1935 as compared with 17 for 1934, which was the highest since 1929. Of the 1,999 enlisted men discharged during the year 1,363, or 68.13 per cent, were for conditions not in line of duty. Of the latter number, 77.24 per cent existed prior to enlistment. Dementia praecox was the leading cause of discharge in 1935; there were 213 cases. This cause was supplanted by tuberculosis in 1934, the first time in more than ten years that it did not occupy first place. The classification "constitutional psychopathic state" held second place in this group with 142 cases, advancing from sixth place in 1934. Tuberculosis, with 138 cases, occupied third place.

During the year there were 1,533,095 days lost from duty for all causes, compared with 1,483,120 in 1934. Days lost from diseases amounted to 1,234,432 and injuries 298,663. The total army had a noneffective rate of 29.5, compared with 30.2 for 1934. The average time lost from duty per patient was 16.6, slightly lower than that for the previous year, 18.2. Gonorrhea was responsible for 158,884 days lost; athletic exercises were second with 59,798 and tuberculosis third with 56,114. To tuberculosis was attributed the greatest amount of time lost per case (146.1 days). Dementia paralytica was second (146.0) and dementia praecox (91.5) third. Cancer was fourth (81.5) in this classification, as compared with its position of third from the lowest in 1934.

There were 5,010 admissions for venereal diseases with 233,775 days lost, compared with 4,632 admissions and 206,784 days lost for 1934, giving a slightly higher admission rate (35.1) in 1935 as compared with 34.4 in 1934. Alcoholism achieved the lowest admission rate for this condition in the past decade, 4.5. The highest (9) was recorded in 1931. Only four cases of typhoid were reported in the army, all in the Philippine Islands, three being in white soldiers. The fourth, in a Filipino, was fatal. There were fourteen admissions for drug addiction during the year as compared with eighteen in 1934.

## CORRECTION

**Betanaphthol Ointment.**—In the prescription entitled "Betanaphthol Ointment" in *THE JOURNAL* February 13, page 555, the quantity of betanaphthol should have been 1.50 Gm. instead of 0.15 Gm.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARKANSAS

**Personal.**—Dr. Thomas C. Watson, Benton, has been appointed medical director of the Tenth District, comprising Saline, Hot Springs and Grant counties.—Dr. Harvey D. Wood, Fayetteville, was the guest of honor at a dinner, January 8, celebrating his ninetieth birthday; he was presented with a chest containing ninety silver dollars.—Dr. Asa C. Watson, England, has been appointed superintendent of the Benton division of the State Hospital, Little Rock.

### CALIFORNIA

**Lane Lectures.**—Dr. Eugene F. Du Bois, professor of medicine, Cornell University Medical College, New York, will deliver the twenty-sixth course of Lane Lectures at Stanford University School of Medicine, San Francisco, April 5-9. His subject will be "Mechanism of Heat Loss and Temperature Regulation."

**First Hobby Show.**—Forty-two members participated in the first hobby show of the Los Angeles County Medical Association the week of January 11. Firearms were exhibited by Drs. Howard Andrews, James R. Dean and Cyril B. Courville. The display included two concertos for piano and orchestra and a rhapsody for two pianos, composed by Dr. Lloyd Mills; excerpts from "Mass in E Flat," a composition by Dr. Lowell S. Goin, and two compositions entitled "Cavaliers" and "Prayer," by Dr. George P. Laton. Stamp collections were displayed by Drs. Stephen G. Seech, Herbert O. Barnes, Charles L. Lowman and John W. Nevius, who specialized in tuberculosis stamps. Wood work was shown by Drs. Philip S. Doane, Jonas C. Kopelowitz, Henry G. T. Bieler and Robert A. Campbell, while Dr. Hans von Briesen exhibited whittling and lithographs. There were oil paintings by Drs. Paul K. Sellow, Saul S. Robinson, Robert H. Kennicott, Marcia A. Patrick, Everett R. Lambertson and Louis K. Guggenheim; photographs by Drs. Abraham Marians, Harold Lincoln Thompson, George Dock and Frank E. McCann. Other exhibitors included:

Dr. Salvatore R. Monaco, pottery.  
Dr. Katherine M. Close, a seascape in tempera.  
Dr. Randall Hutchinson, bead work.  
Dr. Arthur Bowen, hand tooled leather.  
Dr. Joseph C. Savage, heads in charcoal.  
Dr. Paul Z. Hebert, pictorial art in glass.  
Dr. Sven R. Lokrantz, relief art.  
Dr. Franz H. Brandt, penciled landscapes.  
Dr. Cora E. Smith King, a collection of pressed plant life of the west.  
Dr. Harold Dewey Barnard, mounted animals.  
Dr. Norval W. Haddow, "Climatology."  
Dr. Harold F. Whalman, motion pictures in color.  
Dr. Clinton D. Hubbard, sea shells from the seven seas.  
Dr. Raymond L. Schulz, surgical instruments made by himself.  
Dr. Orrie E. Grist, stereopticon pictures.  
Dr. Edward L. Sudlow, books.  
Dr. Frank B. Young, comparative pathologic and physiologic osseous conditions.

In view of the success of the first hobby show, the association plans to hold three such shows next year. One week will be limited to pictorial artists, one to those interested in handicraft, and one to collectors, according to present plans.

### COLORADO

**Lectures in Obstetrics and Pediatrics.**—The division of maternal and child health of the state department of health opened a series of graduate lectures for physicians in the northern and northeastern portions of the state, March 1, under the auspices of the Colorado State Medical Society. Financed by social security funds, the courses will be offered in Sterling, Fort Morgan, Greeley, Fort Collins and Boulder and continue to April 2. Five sessions in each specialty will be held in each town. Lecturers are:

Dr. Leroy A. Calkins, professor of obstetrics and gynecology, University of Kansas School of Medicine, Kansas City.  
Dr. Cuthbert Powell, associate professor of obstetrics and gynecology, University of Colorado School of Medicine, Denver.  
Dr. Everett D. Plass, professor of obstetrics and gynecology, State University of Iowa College of Medicine, Iowa City.  
Dr. Hugh L. Dwyer, associate professor of pediatrics, University of Kansas School of Medicine.  
Dr. Wilford W. Barber, instructor in pediatrics, University of Colorado School of Medicine.  
Dr. William W. Swanson, associate professor of pediatrics, Division of Biological Sciences, University of Chicago.

### CONNECTICUT

**Personal.**—Edward S. Robinson, Ph.D., professor of psychology at Yale University since 1927 and since 1935 director of general graduate studies, died February 27, aged 43, in New Haven Hospital of skull injuries suffered when he was struck by a bicyclist. Dr. Robinson received the degree of doctor of philosophy from the University of Chicago in 1920. He was cooperating editor of the *American Journal of Psychology* and had contributed extensively to the literature of his field.—Benedict Marcus Holden, Hartford, died suddenly in New York, February 19, aged 63. In 1924 Mr. Holden served as foreman of an extraordinary grand jury which investigated the notorious diploma mill frauds, resulting in the exodus from the state of about 200 "quacks."

### DISTRICT OF COLUMBIA

**Personal.**—Dr. Thomas Parran, surgeon general, U. S. Public Health Service, received the honorary degree of doctor of pharmacy from the Philadelphia College of Pharmacy and Science at its "Founders' Day" ceremony, February 23.—Dr. Lewis Harvie Taylor has been elected superintendent of Sibley Memorial Hospital, succeeding the late Charles S. Cole.

**Society News.**—The Washington chapter of the Pan American Medical Association was addressed in Rockville, Md., January 10, by Drs. August S. Boyd, minister of Panama, on "Recollections of Medical Practice in the Tropics," and B. B. Vincent Lyon, Philadelphia, "Gallbladder Disease: Diagnosis, Management and Prevention." Dr. Isidro Castillo, professor of surgery, National University of Buenos Aires Faculty of Medical Sciences, also spoke.—Dr. James G. Townsend, director of health in the Office of Indian Affairs, has been elected president of the Tuberculosis Association of the District of Columbia, succeeding Dr. William C. White.

### FLORIDA

**Hospital News.**—A consulting staff has been appointed for the Florida State Hospital at Chattahoochee. Members include Drs. Henry Mason Smith, Tampa; Ralph N. Greene, Coral Gables; William H. Spiers, Orlando, and Whitman C. McConnell, St. Petersburg, all of whom are former members of the hospital staff.

**Society News.**—At a meeting of the Pasco-Hernando-Citrus County Medical Society in Brooksville, January 15, Drs. James L. Estes and Harold O. Brown, Tampa, among others, spoke on diagnosis and treatment of renal calculi.—Dr. Louis B. Mount, St. Petersburg, addressed the Pinellas County Medical Society, February 5, on "Pruritus Without Skin Eruption."

**Personal.**—Dr. Alfred T. Eide, Lake Placid, was elected a member of the house of representatives of the state legislature at the November election.—Dr. Leonidas M. Anderson, Lake City, formerly president of the Florida Medical Association, was recently guest of honor at a dinner given by the Anderson County Medical Society to celebrate his seventy-fifth birthday. Dr. Anderson completed fifty years in the practice of medicine in 1936 (*THE JOURNAL*, May 16, 1936, p. 1739).—Dr. Frank L. Quillman, formerly of Winter Garden, has been appointed health officer of Orange County with offices in Orlando.

### ILLINOIS

**Society News.**—The Sangamon County Medical Society will be addressed in Springfield, March 25, by Drs. Morris Edward Davis, Chicago, on "Mechanism of Normal Labor" and "Medical Complications of Pregnancy," and Joseph Greengard, Chicago, "Syphilis" and "Tuberculosis."—Dr. Dean D. Lewis, Baltimore, will address the Springfield Medical Club, Springfield, March 23, on "Surgical Significance of Ductless Gland Lesions."—Dr. Albert Graeme Mitchell, Cincinnati, addressed the Peoria City Medical Society, March 16, on "Endocrinology in Childhood."—Dr. Carlo S. Scuderi, Chicago, discussed "Radiographic Interpretations of Bone Tumors" before the Stephenson County Medical Society, Freeport, February 18.

### Chicago

**Annual Hobby Show.**—The Chicago Medical Society is accepting entries for its second annual hobby show, April 7-8. A feature this year will be a special room where physicians may project motion picture films.

**Dr. Loeb Will Give Arno B. Luckhardt Lecture.**—Dr. Leo Loeb, professor emeritus of pathology, Washington University School of Medicine, St. Louis, will present the fourth Arno B. Luckhardt Lecture, March 30, at Billings Hospital, under the auspices of the Delta chapter of Phi Beta Pi. His subject will be "The Biological Basis of Individuality."

children to some private educational establishment instead of to a state school. This could be overcome by making state schools obligatory for all.

In the debate it was pointed out that the policy of marriage bounties in Italy and Germany had not been successful in preventing the decline of population. If the birth rate was to be increased, people must be convinced that the maintenance of the race was desirable. There must be better maternity services, proper nutrition and jobs for children when they became adults. So long as the danger of war persisted, mothers would not be prepared to bear children. A tax on bachelors was suggested and it was stated that there were nearly 200 bachelors in the House, which gave rise to cries of "Shame." A member stated that birth control had not yet reached its limit. At one clinic of which he knew the number of patients who came for advice on how to have a child was equal to those who came for advice as to how to avoid having one. He advocated either not allowing women to take employment or providing state nurseries.

For the government Mr. Hudson, parliamentary secretary to the Ministry of Health, stated that they had been studying the matter for some time and would accept the motion. Although before 1933 our birth rate fell, since that year, for the first time in our history, it had remained stationary, and in the last few years there was a slight increase. It had been suggested that contraceptive measures were the cause of the decline, but there was a great difference between the means and the cause. Lack of houses was suggested as a cause, and as far as rural houses were concerned that was probably true. We had still to decide whether there was an economic urge to reduce families and whether it could be altered. It was useless to discuss what was the optimal population unless steps could be taken to affect population one way or another. At present there existed a large excess of persons in the prime of life. Our adult population was the result of years when the annual number of births was about 900,000. The number of children today was the result of years when the births were between 400,000 and 500,000. Perhaps the estimates of future population being made today by certain statisticians were as wide of the mark as those made a hundred years ago. The government would intensify the inquiry at present proceeding. The motion was agreed to.

The minister's reply is not convincing. He overlooks the fact that the science of statistics is in a much more advanced state today than it was 100 years ago. In particular, Kuczynski's unit, "the net reproduction rate" (THE JOURNAL, Nov. 14, 1936, p. 1646) has only recently been introduced. It indicates accurately the trend of population. In 1933 the net reproduction in England and Wales was 0.734, or less than three fourths of that required to maintain the population. The "slight increase" to which the minister referred, even if maintained, would have little effect on the downward trend. All schemes for encouraging reproduction are open to the objection that they must increase taxation, which is one of the causes of the decline. The tremendous burden of the cost of the social services is a great deterrent to reproduction in taxpayers.

#### Alcohol and Automobile Accidents

At a meeting of the Society for the Study of Inebriety, Dr. H. M. Vernon pointed out that although road accidents have in the last two years diminished a little, fatalities still averages eighteen a day and injuries more than 600. Speed seems to be the most important factor in accidents. The Ministry of Transport attributed a fourth of the accidents to excessive speed, but many other causes in some degree involved this. It had been shown in Rhode Island that, when the average speed was reduced from thirty-seven to thirty-one miles an hour, fatalities were reduced 27 per cent. Dr. Vernon emphasized the importance of the effect of alcohol on the speed factor. In 1935

the committee of the British Medical Association on the "Relation of Alcohol to Road Accidents" stated that such moderate quantities of alcohol as 3 ounces of whisky diminish attention and control and reduce the rapidity and accuracy of coordination of movements of the eyes, hands and legs. These effects are more likely to lead to an accident, the greater the speed. The distance within which a car can be pulled up when a pedestrian or other obstruction is seen varies as the square of the speed. The reaction time is increased from 0.1 to 0.4 second by alcohol, and in addition drivers unconsciously accelerate their speed. Tests made on twenty subjects by means of a motor driving apparatus showed that 2½ ounces of whisky increased the rate of driving 6 per cent and driving errors 13 per cent. The experiment showed the importance of all cars carrying a speedometer.

American data suggest that though alcohol is directly mentioned in only 7 to 10 per cent of fatal road accidents, a third or a fourth are attributable to the action of alcohol on the drivers. A new method of investigation is now being tried—determination of the alcohol content of the blood or urine. It has been shown that from 40 to 63 per cent of persons having one part per thousand of alcohol in their blood are under its influence. The conclusion is that the only safe course for the automobile driver is total abstinence, which should be practiced several hours before driving as well as during it, owing to the slowness with which alcohol disappears from the blood.

#### PARIS

(From Our Regular Correspondent)

Feb. 20, 1937.

#### A Proposed Law to Prevent Venereal Diseases

Nov. 5, 1936, a bill was introduced in the senate aiming to control the rapidly increasing number of cases of syphilis and gonorrhea. The bill is sponsored by the Ministry of Public Health and must pass both the senate and the chamber of deputies before becoming a law. Some of the leading clauses of the proposed law, as it was published in the Dec. 15, 1936, *Siècle médical*, will be cited:

##### PROPHYLAXIS OF VENEREAL DISEASES

SECTION 1.—*Prerogatives and Obligations of Physicians.*—Article 1. Every physician having occasion to treat an individual who either has a venereal disease of recent origin or is likely to have a recurrence of a former or uncured attack is obliged to give the patient a warning regarding the contagious character of the illness and impart information as to the essential features of the present law.

Article 2. If the attending physician ascertains that the infected individual, as the result of neglect of treatment or of the patient's mode of life, exposes one or several others to the disease, he is authorized to notify the public health authorities.

Article 3.—Article 378 of the Penal Code regarding professional secrecy is therefore modified so that physicians whom the present law authorizes or obligates to reveal professional secrets will not be subject to punishment, as would occur in ordinary nonvenereal cases.

SECTION 2.—*Infractions of the Law and Penalties.*—Article 4. Every individual suffering from a venereal disease who knowingly or intentionally communicates the ailment to another person shall be subject to a prison term varying from two to five years, a fine of from 1,000 to 5,000 francs and a loss of civil rights for fifteen years (including the prison term).

Article 5. Every individual suffering from a venereal disease who, without harmful intent, but as the result of imprudence, communicates such disease to another person, shall be subject to the punishment included in section 320 of the Penal Code.

of the hospitals of the state will lecture on their specialties. A six weeks practice period in approved hospitals will be a required part of the course. Additional information may be obtained from the registrar, University of Minnesota, Minneapolis.

### MISSISSIPPI

**Dr. Moore Professor of Pathology.**—Dr. Robert M. Moore, assistant professor of pathology, University of Missouri School of Medicine, Columbia, has been appointed professor of pathology and director of clinical laboratory diagnosis in the University of Mississippi School of Medicine, University, effective September 1, it is reported.

**University Faculty Presents Society's Program.**—Members of the faculty of Vanderbilt University School of Medicine, Nashville, Tenn., presented the program at the quarterly meeting of the Central Medical Society in the Robert E. Lee Hotel, Jackson, March 2. B. E. Mitchell, dean, Millsaps College, Jackson, gave the invocation and the speakers included:

Dr. Hugh J. Morgan, Diagnosis and Treatment of Early and Late Manifestations of Syphilis.

Dr. Barney Brooks, Surgery of the Stomach.

Dr. Lucius E. Burch, Diagnosis and Treatment of Common Gynecological and Obstetrical Diseases.

Dr. Horton R. Casparis, Allergy in Children and Nutritional Problems in Children.

Dr. Waller S. Leathers, Significant Public Health Trends in Mississippi.

Drs. Ernest W. Goodpasture and Hugh J. Morgan conducted a clinical pathologic conference on nephritis. Drs. Felix J. Underwood, state health officer, and Lawrence W. Long, president of the society, both of Jackson, were among other speakers.

### NEBRASKA

**Personal.**—Dr. Frank W. Plehn, Scottsbluff, has been chosen as the town's "Best Citizen of 1936." He is 71 years old.—Dr. Edmund G. Zimmerer, Lincoln, has been appointed assistant epidemiologist in the state department of health to head a division of venereal disease, it is reported.—Dr. Emmett McMahon, Omaha, has been appointed medical director of the Douglas County Hospital, Omaha, succeeding Dr. James W. Martin, it is reported.

### NEVADA

**Hospital News.**—A government hospital for veterans is to be erected in Reno on a site donated by the city.—A new wing is under construction at the Washoe General Hospital, Reno. It will be occupied by the maternity service, including delivery room, nursery and private rooms.

### NEW YORK

**Society Condemns Motion Picture.**—The Medical Society of the County of Erie adopted a resolution at its February meeting condemning a motion picture entitled "A Doctor's Diary" as a "malicious attack on the medical profession." The resolution states that "the author's conception of the code of ethics is absurd, and attempts to portray the staff of a private metropolitan hospital as an avaricious crew of vultures who are defied by a temperamental nurse, and an heroic intern who is shot by the aggrieved mother of a child prodigy during a suit for malpractice."

**Society News.**—Henry F. Vaughan, Dr.P.H., Detroit, addressed the Medical Society of the County of Nassau, Mineola, February 23, on "The Place of the Practicing Physician in the Health Program."—Dr. Frederick S. Wetherell, Syracuse, addressed the Cayuga County Medical Society, Auburn, January 21, on "The Relation of the Sympathetic Nervous System to Problems Arising in General Practice."—Dr. Leo E. Gibson, Syracuse, spoke on "Infections of the Kidney and Treatment," January 15, before the Cortland County Medical Society, Cortland.—Dr. William Cook Spain, New York, addressed the Suffolk County Medical Society, at its quarterly meeting January 27 in Patchogue, on "Asthma in Children."—Drs. Edwin A. Locke, Williamstown, Mass., and George M. MacKenzie, Cooperstown, addressed the Medical Society of the County of Albany, February 24, on "General and Symptomatic Treatment of Pneumonia" and "Specific Therapy of Pneumococcal Lobar Pneumonia" respectively.—Dr. Howard P. Doub, Detroit, addressed the Central New York X-Ray Society, February 6, in Syracuse, on "Radiologic Conditions of the Spine."

### New York City

**Dr. Carrel Receives Newman Award.**—Dr. Alexis Carrel of the Rockefeller Institute for Medical Research, received the eighth Cardinal Newman Award of the Newman Foundation at a ceremony at the University of Illinois, Urbana, February 21.

The award is conferred annually on a person "who has made an outstanding contribution to the enrichment of human life in the fields of statesmanship, education, art, science and humanitarianism."

**Dinner to Dr. Saul Adler.**—Dr. Saul Adler, professor of parasitology at the Hebrew University in Jerusalem, was the guest of honor at a dinner given by the American Jewish Physicians' Committee at the Hotel Waldorf-Astoria, February 1. Among the speakers were Drs. Nathan O. Ratnoff, president, and Israel S. Wechsler, secretary, of the committee, and Dr. Emanuel Libman. Dr. Adler gave addresses at Mount Sinai Hospital, February 8, on "The Leishmaniasis and Their Transmission" and, February 15, on "The Human Blood Spirochetes."

**Society News.**—Dr. Felix R. Nager, Zurich, Switzerland, addressed the section of otolaryngology of the New York Academy of Medicine, February 17, on "Disease of the Labyrinthine Capsule."—Dr. Vally Menkin, Boston, among others, addressed the New York Pathological Society, February 25, on "Recent Studies on Inflammation."—Dr. Gilbert J. Thomas, Minneapolis, addressed the New York Society of the American Urological Association, March 3, on "Factors Favoring Non-progression of Certain Tuberculous Lesions of the Genito-Urinary Tract."—Drs. Francis F. Schwentker, Baltimore, and Charles F. McKhann, Boston, addressed the Medical Society of the County of Kings, February 16, on "Certain Aspects of Serum Therapy in Meningococcus Meningitis" and "Tissue Protein and Blood Coagulation" respectively.—At a meeting of the Brooklyn Thoracic Society, February 19, the speakers were Drs. Nagla Mary Laf Loofy, on "The Sedimentation Rate in Clinical Pulmonary Tuberculosis" and Richard H. Overholt, Boston, "Selective Thoracoplasty and Lung Immobilization for Pulmonary Tuberculosis."

### NORTH CAROLINA

**Special Society Meetings.**—Dr. Julian W. Ashby, Raleigh, was elected president of the North Carolina Neuro-Psychiatric Association at its third annual meeting at Wake Forest, January 29.—The North Carolina Society for Mental Hygiene was recently organized at a meeting in Raleigh, with Ernest R. Groves, B.D., professor of sociology, University of North Carolina, Chapel Hill, as president, and Harry W. Crane, Ph.D., Durham, secretary. Dr. Beverley R. Tucker, Richmond, Va., gave the principal address at the meeting.—At the annual meeting of the North Carolina Academy of Surgery in Greensboro, February 2, the guest speakers were Drs. Gilson C. Engel and Chevalier L. Jackson, Philadelphia, on "The Value of Operation in Peptic Ulcer" and "The Bronchoscope as a Diagnostic Agent in Tumors of the Chest" respectively. Dr. Frank K. Boland, Atlanta, presented to the academy a gavel made of wood from the estate of Dr. Crawford W. Long.

### NORTH DAKOTA

**Honor Dean for Years of Service.**—Dr. Harley E. French, dean of the University of North Dakota School of Medicine, Grand Forks, was guest of honor at a dinner given by students and alumni of the school February 5, celebrating his twenty-fifth anniversary in the deanship. Dr. French is 63 years old, a native of Indiana and a graduate of Northwestern University Medical School, Chicago. He was professor of anatomy and physiology at the University of South Dakota School of Medicine from 1907 to 1911. Since 1911 he has been dean and professor of anatomy at North Dakota, except one year which he spent on leave of absence as assistant professor of anatomy at the University of Pennsylvania School of Medicine, Philadelphia (1925-1926). He was secretary of the state board of health, 1921-1923, and president of the North Dakota State Medical Association, 1921-1922.

### OHIO

**Hanna Lectures.**—Dr. Siegfried J. Thannhauser, associate professor of medicine, Tufts College Medical School, Boston, formerly professor of medicine at the University of Freiburg, Germany, delivered the fortieth Hanna Lecture under the joint auspices of the Cleveland section of the Society for Experimental Biology and Medicine and the experimental medicine section of the Academy of Medicine of Cleveland, February 12. His subject was "Cholesterol: Its Physiological and Clinical Implications." Dr. Leonard Colebrook, honorary director of research laboratories at Queen Charlotte's Hospital, London, delivered the forty-first lecture, March 9, on "The Control of Hemolytic Streptococcal Infection with Particular Reference to Puerperal Fever."

In the discussion, Moulounguet stated that the fever often observed in endometriomas leads one to suspect a genital tuberculosis. The rise of temperature is continuous but is more marked during menstruation. He endorsed the view of the authors that useless dissection of pelvic metastases is to be avoided. One should be guarded as to the prognosis, because recurrence is common. The poor results following operation in his cases have led him to consider irradiation (castration dose) as the preferable treatment.

Mondor believes that internal hemorrhage, i. e., into the free peritoneal cavity, when not related to pregnancy, is frequently due to ovarian endometriomas. He also preferred irradiation.

### Associated Vaccinations

Prof. G. Ramon of the Pasteur Institute reviews the question of associated vaccinations in the September 1936 *Revue d'immunologie*. He has found experimentally that one is able to obtain a multivalent immunization. The addition to the antigens of nonspecific substances greatly increases their activity in the organism. If, for example, the tetanus anatoxin is mixed with the typhoid paratyphoid A and B vaccine, one observes the appearance of tetanus antitoxins and typhoid agglutinins in larger amounts than if these two vaccinations were given separately. The results are the same with diphtheria and with staphylococcus anatoxin alone or associated. These experimental observations have been confirmed clinically. It is evident that there are many advantages in immunizing an individual against several diseases without more effort than is required to immunize against a single one.

In the same issue of this journal appears an article by Sacquépée, Pilod and Jude, who report the results of the use of associated vaccines (antidiphtheria, antitetanic and antitypho-paratyphoid) in 418 cases. It was found that 99.58 per cent were immunized against diphtheria eight days after the last injection. Ten per cent of these persons became receptive again about ten months later and were given a second injection.

### BERLIN

Feb. 16, 1937.

### The Investigation of Goiter and Cretinism in Bavaria

This investigation was initiated ten years ago by the German Institute of Psychiatric Research of Munich. As Dr. Lang of the institute staff reports, the districts studied were primarily those in which there was a high incidence of goiter and cretinism. Statistical and genealogical data were first collected, records being made of some 1,700 mentally deficient persons and their family trees established. It was revealed as an incontestable fact that within the districts surveyed feeble-mindedness unaccompanied by external signs of cretinism was more prevalent than cretinism itself (the term "cretinism" is here taken to include both the cretin and the cretinoid types). Feeble-mindedness without external signs of cretinism was found to be extremely common among the siblings of cretin and cretinoid subjects. Conversely, cretinism was encountered with far more relative frequency among the siblings of feeble-minded persons who presented no somatic anomalies than among the population of the districts investigated as a whole. Full cretins exhibiting no mental deficiency were seen on rare occasions. The persons studied represented the whole gamut of transitional types, from the classic cretin through the severe and mild cretinoid to the feeble-minded person without physical defects. It follows that the forms of feeble-mindedness encountered in a zone of goiter and cretinism must be in great measure influenced by the noxa which gives rise to these diseases. Specific predispositions conducing to cretinism may be considered nonexistent, the more so since among the parents whose offspring are cretins or feeble-minded the incidence of intermarriage was found to

be no greater than among the population as a whole. After studying the regional distribution of the endemic disorders mentioned, Dr. Lang traced a progressive increase in incidence from the southern and western section of the region toward the northern and eastern sections. This fact, together with consideration of such geological phenomena as weathering of soil, led to the setting up of a so-called soil decomposition theory of endemic goiter, cretinism and feeble-mindedness. This theory is based almost entirely on the physical factors underlying the production of a soil in which the noxa of goiter is present. Systematic computations have revealed a clear interrelation between the radioactivity of a soil and of the ground-air and the severity of endemic goiter. It was furthermore disclosed that besides the quantitative difference in the content of ground-air emanations there is also a qualitative difference; in severely affected goiter zones a greater quantity of radon is found, in goiter-free regions more thoron is found. These facts were elicited from investigation of various districts in the Alpine and other mountainous regions of Germany. The high values of the radioactive elements in the atmosphere of many sections of the northerly calcareous Alps, values that seemed virtually inexplicable from the geological point of view, were explained as due to the strikingly high percentage of radioactive minerals encountered in those areas.

Since it seemed improbable that radioactivity of water, in contrast to that of air, could play any part in the origin of endemic goiter, few determinations with regard to the radioactivity of water were attempted. Examinations of soil specimens spoke against the theory of iodine deficiency. In various districts the respective populations of which were unequally affected with goiter, experimentation with white rats was undertaken. These animals received an abundantly varied regimen especially rich in iodine and vitamins; all the food products were imported from completely goiter-free areas. The water and the hygienic surroundings conformed to these conditions. The rats accordingly received nothing indigenous to the place of experiment except the air they breathed, nor had they any direct contact with the ground. Nevertheless, in from three to five months goiter made its appearance among the animals and especially among those which were being kept within an exceptionally well defined goiter zone.

For the past two years the following type of experiment has been carried on at a place located within a well known goiter zone. Rats are shut up in a cage and receive a supply of air from which the local emanation has been removed. According to the theory underlying these as yet unfinished tests, the animals should remain free from goiter.

Should proofs be forthcoming that the natural radioactivity of air and soil are the decisive etiologic factors in endemic goiter and its accompanying phenomena, any basic attack on this type of noxa will, of course, be a task of more than ordinary difficulty. Still there remains the hypothetical possibility that the amount of emanation escaping from the ground may be diminished by mixing with the soil in question large quantities of organic matter. Preliminary experimentation along this line is in progress.

### Cerebral Abscesses and Their Treatment

The Parisian surgeon Clovis Vincent recently discussed cerebral abscesses and their treatment before the Berlin Medical Society. He described a new surgical treatment of intraparenchymatous abscess of the cerebral hemisphere. His point of departure was the practical observation that, if life is imperiled by a brain abscess, the edema that forms in the neighborhood of the abscess is more largely responsible than the general infection. This edema may lead to an increased pressure on the brain and to the compression of vitally important centers. Consequently, the next consideration after localization of the abscess focus is how this compression may be

## WISCONSIN

**State Board of Health Elects.**—Dr. John J. Seelman, Milwaukee, was chosen president-elect of the state board of health at a recent meeting; Dr. Joseph Dean, Madison, became president and Dr. Mina B. Glasier, Bloomington, vice president.

**Personal.**—Dr. Harry V. Gibson, Fairchild, has been appointed health officer of a new unit organized in Eau Claire County, one of three demonstration units set up with state and federal funds.—Dr. John P. Koehler, Milwaukee health commissioner, recently celebrated the twentieth anniversary of his entrance into public health work in Milwaukee. He joined the staff in 1917 as school physician and became deputy health commissioner in 1918, but resigned in 1920 to do other work. In 1925 he was made health commissioner.—Dr. Edward R. Krumbiegel, Milwaukee, has been appointed head of the division of contagious diseases in the Milwaukee Health Department, succeeding the late Dr. Robert E. Hickey.

## WYOMING

**Annual Registration Due April 1.**—All practitioners of medicine and surgery licensed to practice in Wyoming are required by law to register on or before April 1 with the secretary of the board of medical examiners and to pay a fee of \$2.50. If a licensee fails to pay the fee within three months after April 1, his license can be annulled, and if annulled it will be reinstated only on his paying the stated fee, plus \$5 as a penalty.

## GENERAL

**Negro Health Week.**—The twenty-third annual observance of National Negro Health Week will be held April 4-11. "The Health Agency and Its Relation to the Community" is the topic for 1937.

**Another Fraudulent Salesman.**—Physicians are warned to beware of a man who gives the name H. G. Gabel of Aurora, Ill. He claims to be the owner of the "Illinois Products and Chemical Co." and sells bottles to physicians. According to information received by the American Medical Association, this man delivers the first order and collects for it, but collects for the second and does not deliver.

**Sectional Meeting on Physical Therapy.**—The American Congress of Physical Therapy will hold a sectional meeting at Newark, N. J., April 2, in cooperation with the New York and Pennsylvania Physical Therapy societies, the Essex County Medical Society and the Academy of Medicine of Northern New Jersey. The speakers will include Drs. Richard Kovacs, New York, on "Development and Uses of Present Methods of Electrotherapy"; Albert A. Martucci, Philadelphia, "Treatment of Painful Bursae About the Shoulder"; Grant E. Ward, Baltimore, "Present Status of Electrosurgery," and Charles F. McCarty, Brooklyn, "Economics of Physical Medicine."

**American Association of Anatomists.**—The fifty-third session of the American Association of Anatomists will be held at the University of Toronto, March 25-27. Headquarters will be at the Royal York Hotel. On the program of 150 papers a few of the speakers are:

Dr. C. U. Ariens Kappers, University of Amsterdam, Holland, The Hypothalamic Autonomic Centers.  
Dr. Herbert S. Gasser, Rockefeller Institute for Medical Research, New York, Physiology of the Neuron (introduction to a symposium).  
Dr. Robert R. Bensley, Chicago, Distribution of Lipids in Protoplasm and Their Relation to Its Constitution.  
Dr. Wingate Todd, Cleveland, Criteria of Age Changes in the Growing Body.  
Dr. Ian MacLaren Thompson, Winnipeg, Manit., Experimental Human Anatomy, Exemplified by Cutaneous Innervation.  
Richard E. Scammon, Ph.D., Minneapolis, The Quantitative Method in Anatomical Research.  
Dr. Jacob Parsons Schaeffer, Philadelphia, The Problems of Variation.  
Dr. George L. Streeter, Baltimore, Carnegie Institution of Washington, A Genetic Factor in Development of Bone.  
Edgar Allen, Ph.D., Dr. George M. Smith and William U. Gardner, Ph.D., New Haven, Conn., Growth of Ovaries and Genital Tract in Response to Hormones as Studied by the Colchicine Technique.  
Robert Gaunt, New York, and Warren O. Nelson, Detroit, The Adrenal-Pituitary Relationship in Lactation.

Dr. Frederick T. Lewis, Boston, president of the association, will deliver his official address at a dinner Friday evening at the Royal York, on "The Fundamentals of Cell Shape."

**Women's Field Army for Cancer Control.**—The American Society for the Control of Cancer announces that the recently organized Women's Field Army will conduct an intensive campaign for members during the week of March 21-27. Organization is already under way in thirty-eight states under the direction of Mrs. Grace Morrison Poole, dean of Stoneleigh College, Rye Beach, N. H., a former president of the General Federation of Women's Clubs, and Mrs. Marjorie B. Illig, Onset, Mass., chairman of the National Health Division of the federation of women's clubs. Members will pay \$1 each, which will be placed in a fund to be distributed by the central

office of the society, as follows: 70 per cent to the state executive committee to be spent locally, 20 per cent to the central office in New York for expenses involved in the field, and 10 per cent to a contingent fund. The "army" will be organized with the following units: state executive committee composed of the cancer committee of the state medical society and the state commander; state advisory board composed of the executive committee and influential persons it selects; a state commander; vice commanders; state women's division composed of the commanders and representatives of women's organizations; captains, lieutenants and local units. Through meetings, radio, newspapers and magazines, exhibits and distribution of literature an educational campaign will be launched.

**International Fever Therapy Conference in New York.**

—The First International Conference on Fever Therapy will be held at the Waldorf-Astoria, New York, March 29-31. Dr. Willard C. Rappleye, dean of Columbia University College of Physicians and Surgeons, will welcome the conference; Prof. Pierre Abrami, professor of clinical medicine, University of Paris, will respond, and a message will be presented from Prof. Julius Wagner-Jauregg, Vienna, who is honorary chairman of the conference. Among foreign speakers on the program will be:

Dr. Charles Richet Jr., Paris, Posology of Therapeutic Fever.  
Dr. Charles Gernez, Lille, France, Physiology of Fever.  
Prof. Constantin Levaditi, Paris, Experimental Pathology.  
Dr. Henri Claude, Paris, Psychiatry.  
Dr. Albert Bessemans, Ghent, Belgium, Experimental Pathology (in a program on syphilis).  
Dr. Americo Valerio, Rio de Janeiro, Fever Therapy in Chronic Infectious Gonorrhea.

American physicians who will present papers include:

Dr. Stafford L. Warren, Rochester, N. Y., Chloride Balance in Artificial Fever Therapy.  
Drs. Franklin G. Ebaugh, Clarke H. Barnacle and Jack R. Ewalt, Denver, Psychiatric Aspects of Artificial Fever Therapy.  
Dr. Frank W. Hartman, Detroit, Pathologic Changes Produced by Artificial Fever Therapy in Animals and Man.  
Dr. Clarence A. Neymann and Mr. S. L. Osborne, Chicago, Electropexia in Rheumatic Endocarditis, Chorea and Certain Other Childhood Conditions.  
Drs. Abram E. Bennett and Paul T. Cash, Omaha, Relief of Neuritic Pain by Artificial Fever Therapy Obtained in Forty Cases.  
Drs. Leland E. Hinsie and Joseph R. Blalock, New York, Serology in General Paralysis of the Insane Following Treatment.  
Drs. Walter M. Simpson and Herbert Worley Kendell, Dayton, Ohio, Treatment of Syphilis with Artificial Fever Combined with Chemotherapy.  
Dr. William Bierman, New York, Treatment of Gonorrhea in Women by Means of Combined Systemic and Additive Local Heat.  
Drs. Truman G. Schnabel and Ferdinand Fetter, Philadelphia, Fever Therapy in Gonococcal Arthritis.

The first day's meeting will be at the College of Physicians and Surgeons of Columbia University and the remaining days at the Waldorf-Astoria, where exhibits and displays of apparatus will be on view.

**Meetings in Chicago.**—The American Association of Pathologists and Bacteriologists, the American Association of Immunologists, the American Association for Cancer Research and the American and Canadian section of the International Association of Medical Museums will hold their annual meetings March 24-26 at Northwestern University Medical School, Chicago. At the session of the pathologists and bacteriologists March 25-26, the speakers will include:

Dr. Carl V. Weller, Ann Arbor, Mich., The Intrinsic Factor in the Genesis of Tumors.  
Dr. Simeon Burt Wolbach, Boston, The Immediate Response to Carcinogenic Chemicals.  
Dr. Francis Peyton Rous, New York, Relation of Filtrable Agents to Tumor Formation.  
Dr. Leo Loeb, St. Louis, Sex Hormones and Their Relation to Tumors.  
Dr. Thomas Francis Jr., New York, Action of Immune Serum on the Influenza Virus in Vitro.  
Dr. Elexious T. Bell, Minneapolis, Tubular Disease of the Kidneys.

The association of immunologists will meet jointly with the pathologists and bacteriologists Thursday morning March 25. Other speakers on its program, which begins March 24, will be:

Dr. Harry S. Eagle, Baltimore, Rapid Detoxication of Diphtheria Toxin by Diazo Compounds and by Formaldehyde.  
Dr. Edward C. Rosenow, Rochester, Minn., Studies on the Etiology of the Current Epidemic of Influenza.  
Dr. Sanford B. Hooker, Boston, The Nature of Antibody (presidential address).

The association for cancer research will meet March 24. Twenty-eight papers will be read, including the following:

Clarence C. Little, Sc.D., Bar Harbor, Me., Genetics of Tumors and of Other Structural Abnormalities in the C57 Black Strain of Mice.  
Miss Maud Slye, Chicago, The Genetics of Cancer.  
Dr. Shields Warren and Lloyd C. Fogg, Ph.D., Boston, Cytoplasmic Changes Induced by Radiation of Various Wavelengths.

At the session of the association of medical museums, March 24, a feature will be a symposium on "The Use of Gross Specimens in the Teaching of Pathology," presented by Drs. James S. McCartney, Minneapolis; William C. von Glahn, New York; Howard T. Karsner, Cleveland, and Edward B. Krumbhaar, Philadelphia.

ing to age here shows considerable correspondence. The commitment to an asylum comes for the women patients only about six months later than for the men. This phenomenon is all the more striking because the establishment of the previous venereal infection, which underlies this type of insanity, presents considerably greater variation as between men and women.

## MOSCOW

(From Our Regular Correspondent)

Feb. 2, 1937.

### The Second All-Union Conference of Psychiatrists

The second All-Union Conference of Neuropathologists and Psychiatrists was held in the Moscow Polytechnical Museum Dec. 25-29, 1936. About 250 delegates and more than a thousand guests were present. The principal topics were (1) organization of neuropsychiatric aid, (2) clinical symptoms and treatment of skull injuries, (3) brain tumors and (4) treatment of schizophrenia.

Prof. N. N. Burdenko, in his report on the second problem, noted that most injuries of the skull and brain get well quicker and with less complications without surgical intervention. Prof. L. E. Omorokov of Kazan stated that 16 per cent of all brain injuries result in epilepsy. He cured a number of epileptic patients by introducing air into the ventricles of the brain where it was missing. After this treatment, epileptic fits became much more rare.

The third paper was read by Professor Nikitin of Leningrad. A lively discussion was held on the question of surgical intervention. Professor Burdenko contended that not all brain tumors must be operated on. The operation must be done only when the patient is reasonably sure of being returned to work in a normal condition.

The fourth and fifth days of the conference were devoted to the diagnosis and treatment of schizophrenia. This question was discussed by Prof. V. A. Giliarovsky of Moscow, V. P. Osipov of Leningrad, V. A. Vnukov of Moscow, M. I. Sereysky of Moscow and many others. Professor Ostankov of Moscow noted that schizophrenia is far from being as common as it is now diagnosed. This diagnosis has been made too easily by neurologists and psychiatrists without enough justification. Many physicians now diagnose as "reactive status" many conditions that formerly were in the same range as schizophrenia. This means that the disease is not as frequent as many experienced physicians think.

The sleeping treatment of schizophrenia, introduced by the late I. P. Pavlov, was discussed by Prof. A. S. Ivanov-Smolensky of Leningrad. If cortical nerve cells are strongly stimulated for a prolonged period they go into a state of inhibition. Pavlov concluded that in cases of stupor there exists a diffusely spread stimulation in the central nervous system. This inhibition preserves nerve cells from destruction. Thus the sleep method was elaborated. It consists in putting the patient to sleep for from five to twelve and a half days by narcosis.

Most specialists, among them Professor Kornfeld of Moscow, formerly of Berlin, who described mild cases of this psychopathic condition nine years ago, stated that the sleep treatment is most promising. Others proposed insulin treatment and infection of the patient with malaria.

The conference was closed after this prolonged discussion. G. N. Kaminsky, the commissar of health, stated in his address that a number of new modern hospitals and other institutions for psychiatric patients will be built in the near future. There is a great deal of improvement to be made, and the demands of this conference for temporary improvements will be met immediately. The conference elected a committee after deciding to set up a permanent organization of neuropathologists and psychiatrists. M. B. Krol was chosen chairman.

## Artificial Abortion

The People's Commissariat of Health published a list of medical indications for the operation of artificial abortion. These include fifteen severe diseases. However, permission must be granted for performing the operation. The pregnant woman must be examined by a commission of three physicians, working under the auspices of health departments. If they cannot arrive at a conclusion about the pregnant woman's disease, she must be sent for detailed examination to a suitable medical institution. There is a special tax for abortion calculated from the cost of the operation and maintenance of the patient. In case a woman enters a hospital with symptoms of an illegal abortion, the doctor is required to register the fact and give detailed information to the prosecuting magistrate.

## Some Facts About Health Improvement

Research work on mother and child protection is concentrated in seventeen special institutes, with a central one in Moscow. As supplementary places there are special sanatoriums, maternity institutions, homes for orphans or abandoned children up to 1 year of age and children's homes for those over 1 year. These numerous establishments have helped to decrease the mortality rate.

The improvement in health conditions of adults is illustrated by some facts about the Red Army, presented in the accompanying table.

*Comparative Measurements of Soldiers in  
Tsarist and Red Armies*

	Average Weight	Average Height	Chest Circumference
Tsarist army	128-140 lbs.	5 ft. 3.9 inches-5 ft. 4.30 inches	32.4-34.10 inches
Red army....	143.5-151 lbs.	5 ft. 5.5 inches-5 ft. 6.25 inches	34.5-39.85 inches

In the first six months of 1936 there were 200 cases of smallpox, compared with 72,000 registered cases in 1913. Malaria was reduced by from 30 to 35 per cent during the first half of 1936, compared with the same period of 1935. Cases of spotted fever were reduced to a tenth of what they were in 1933.

## Soviet Medical News in Brief

In the Union of Socialist Soviet Republics there are 42,000 women physicians, comprising about half of all the doctors in the country. Only 2,000 of them were educated prior to the revolution. More than 11,000 women work in various research institutes, a figure equal to 29 per cent of the total number of workers in these institutes.

According to the government decree of June 27, 1936, there were recorded up to Nov. 1, 1936, about 129,000 mothers having seven children and more who must receive state aid. In Moscow Province 8,396 mothers have seven children, 3,125 have eight, 944 have nine, 295 have ten and seventy-three have eleven.

## The Fight Against Colds

The Medical Council and the People's Commissariat of Health called a meeting, Nov. 14-16, 1936, to consider measures for combating the common cold.

Dr. A. A. Smorodintzev from the Leningrad Pasteur Institute made a report on the rôle of the filtrable viruses in colds. He succeeded in obtaining from patients a filtrable virus, which produced in pigs, on inoculation of the respiratory tract, a disease similar to colds. There is observed a great increase in pneumococci and Pfeiffer bacilli in the pharynx in the first days of the disease.

November 15, Prof. D. M. Rossijsky spoke about the prevention and treatment of colds. Vaccines for this purpose give poor results, probably because the etiology of colds is unknown. The meeting passed a resolution recommending routine prophylaxis.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Feb. 20, 1937.

#### National Advisory Councils

It is proposed to appoint two national advisory councils, one for England and Wales, the other for Scotland, whose duty it will be to survey the field of physical training and to advise on the needs of development and how they can best be met. They will suggest means of publicity and propaganda. Each national advisory council will be composed of about thirty men and women selected for their knowledge of the work of local authorities and of national voluntary bodies. A grants committee, consisting of three members, will receive and examine applications for grants.

#### LOCAL COMMITTEES

It is proposed to promote the establishment of local committees consisting of representatives of the local educational authorities, voluntary bodies and others who have special knowledge and experience. On the local committees will largely depend the creation of an active public interest and the encouragement of assistance from voluntary and other sources.

#### THE NATIONAL TRAINING COLLEGE

The National Training College, to be established, will be for the training of leaders to organize recreational physical training, but it should ultimately influence the conduct of physical education of all kinds throughout the country. It is contemplated that the college should investigate some of the problems connected with the physiology of physical training. While the training of teachers for the schools will not be one of its main functions, it will be used to help to make good any deficiency in the supply of teachers trained in the use of gymnastic apparatus. Although women are not excluded from the college, its main function will be to train men, as there are already specialist colleges of physical training for women.

#### Rejection of Bill Concerning Professional Secrets

In England no such right of professional secrecy as exists in France is recognized by the law. In the House of Commons Sir Ernest Graham-Little (dermatologist and representative of London University) moved the second reading of the medical practitioners' communications (privilege) bill. He said that the protection asked for had been rendered necessary by what had occurred in the last twenty years. In 1916 the Royal Commission on Venereal Diseases demonstrated that special measures were necessary to combat these diseases. The government took up the recommendations and made a series of regulations. The commission stressed the importance of secrecy in the arrangements made to combat venereal diseases and the necessity of the patient being assured of secrecy. At the hospital with which Sir Ernest was connected there was a special officer who kept a secret register of the patients treated. The case had occurred of a pathologist who was cited at an assize court and refused to produce documents or give evidence. The judge ruled that physicians were normally under the duty of keeping inviolate the knowledge which they might acquire in treating patients and indeed might become liable to civil action if without lawful excuse they broke that confidence, but in a court of law a physician had no privilege similar to that of a lawyer. The whole gamut of medical practice was now becoming invaded by the state and therefore it was not only venereal diseases that were concerned. The whole trend of public health administration was to get early and efficient treatment. In no case was this more important than in the prevention of maternal mortality. The highest incidence was among young unmarried mothers. If they had no confidence in professional secrecy

they would say nothing about their condition and the system of antepartum treatment would be impaired. The only alternative for the physician who refused to give evidence in court was to base his refusal on medical privilege and submit to imprisonment. That course was recommended to him by the great body of professional opinion in the country.

For the government Solicitor General O'Connor opposed the bill. He said that there were a few cases in which greater injustice might be done by requiring the truth than by permitting it to be withheld, such as matters between man and wife, the evidence of judges and jurymen as to what had taken place when they were acting judicially, state secrets, and matters in which decency forbade disclosure. The only other case at all analogous to the one put forward for the bill was that of communications between a client and his lawyer. But here it was the privilege of the client and not of the lawyer to withhold information. The bill contained no definition of privilege. Was it of the physician or the patient? He was inclined to think that it was of the physician. If anything like the bill was passed there would be some remarkable consequences. Supposing a person found dying of assault told a physician who had done it, the bill gave the physician a privilege against disclosure. Supposing a physician was called to a case of criminal abortion and learned who induced it, the bill would prevent him from doing his duty as a citizen and telling the police. In divorce cases many wives obtained relief from an intolerable burden because they had been able to find the physician who had been treating their husband. There was hardly any branch of the law, civil or criminal, in which the bill, if passed, would not impede the administration of justice. The motion for rejection was agreed to.

#### Inquiry Into the Decline of Population

Though statisticians have shown for some years that the decline of our population is imminent, only recently has the fact received much public attention. It has at least become a subject of debate in the House of Commons. Mr. Cartland moved a resolution that the tendency to decline may constitute a danger to the British Empire and to the economic well being of the nation and requesting the government to institute an inquiry. He said that experts agreed that our population was bound to fall within twenty years. The birth rate had been falling steadily since 1875. It was true that there had been at the same time an increase of population, but that was due almost entirely to a remarkable fall in the death rate. Within three years we should be faced with the fact that the number of births for the first time would no longer exceed the deaths. In the next eight years there would be half a million fewer juveniles available for employment. Under the housing scheme 1,000,000 new houses per annum were being provided. With the present decline of population the housing need in twenty years would drop to 4,500. The empire had reached the edge of an abyss.

Mr. Sandys, who seconded, said that the present English birth rate was such as to lose one fourth of the population in a generation. The main reason for the decline was the spreading knowledge and practice of birth control. From the point of view of defense, a great empire whose population was declining and also, on the average, growing older, was peculiarly vulnerable to attack. The most serious problem was the standard of living. A period would be reached when a decreasing number of workers would have to support an increasing number of old people. There were two remedies. Birth control could be made illegal, but in the opinion of most people that would be a retrograde step. The other course was to alter the social and economic conditions so as to make people want to have larger families. (This gave rise to cheers from the labor party.) Among the reasons why people did not wish to have many children was the cost of education. Those who could not afford it felt that their social status required them to send their

## Deaths

**William Alanson White**, an Associate Fellow of the American Medical Association, medical superintendent of St. Elizabeths Hospital since 1903, and since 1904 professor of psychiatry at the George Washington University School of Medicine, Washington, D. C., died March 7, of pneumonia and influenza, aged 67, in his apartment at the hospital.

Dr. White was born in Brooklyn, Jan. 24, 1870. He was educated in the public schools of Brooklyn and at Cornell University; received a medical degree from Long Island College Hospital, Brooklyn, in 1891; was ambulance surgeon and house surgeon, Alms and Work House, Blackwell's Island, N. Y., house physician and surgeon, Long Island College Hospital, Brooklyn, assistant physician at the Binghamton (N. Y.) State Hospital in 1892 and resigned as first assistant physician in 1903 to become superintendent of St. Elizabeths, then known as the Government Hospital for the Insane. He was formerly a professor of nervous and mental diseases at Georgetown University School of Medicine and clinical professor of neurology at George Washington, and was first lecturer on military psychiatry at the army and navy medical schools.

Dr. White was a fellow of the American College of Physicians, a member of the Association for Research in Nervous and Mental Disease and the American Neurological Association, a member and past president of the American Psychoanalytic Association, the American Psychiatric Association and the American Psychopathological Association, and past president of the Society of Mental Hygiene of the District of Columbia. Dr. White was also a member of the administrative board of the Institute of Child Guidance of the Commonwealth Fund, New York, the executive committee of the National Committee for Mental Hygiene, the Federal Board of Hospitalization, the Washington Academy of Sciences and the American Medico-Psychological Association. In 1930 he was president of the first International Congress on Mental Hygiene and in 1932 was president of the governing board of the International Committee for Mental Hygiene.

Dr. White was the author of numerous works on neurology and psychiatry, among which were "Outlines of Psychiatry," "Mental Mechanisms," "Mechanisms of Character Formation" and "Principles of Mental Hygiene"; co-author with Dr. Smith E. Jelliffe of "Diseases of the Nervous System"; co-author with Dr. Morris Fishbein of "Why Men Fail"; editor and translator with Dr. Jelliffe of "The Psychic Treatment of Nervous Disorders" in 1905, editor with Dr. Jelliffe of a series of monographs on nervous and mental diseases and of two volumes of "Modern Treatment of Nervous and Mental Diseases" and editor of the *Psychoanalytic Review*. He was awarded honorary degrees by Georgetown University in 1925, Washington University, St. Louis, in 1932, Boston University in 1936 and George Washington University in 1937. In 1929 he gave the Kober Lecture at Georgetown University and in 1935 the Salmon Lectures of the New York Academy of Medicine.

As a pioneer in the field of psychology and psychiatry, a brilliant teacher, an inspiration to young men and the builder of a great institution along humanitarian lines, Dr. White will long be remembered.

**Frederick Julius Gaenslen** Member of the Council on Physical Therapy of the American Medical Association from 1931 to 1936, died, March 11, at his home in Milwaukee, aged 59. Dr. Gaenslen was born in Milwaukee, Dec. 7, 1877. He received the bachelor of science degree from the University of Wisconsin in 1899 and the medical degree from Johns Hopkins University School of Medicine, Baltimore, in 1903. After his internship at the German Hospital, now known as the Lenox Hill Hospital, New York, from 1903 to 1906, he engaged in general practice in Milwaukee from 1906 to 1912, when he began specializing in orthopedic surgery. Later he became director of the department of orthopedic surgery and associate professor at the Marquette University School of Medicine, Milwaukee; since 1925 he had been professor of orthopedic surgery at the University of Wisconsin Medical School, Madison. During the five and one-half years as a member of the Council on Physical Therapy, he served as vice chairman, chairman of the Committee on Orthopedic Appliances, on Scientific Exhibit, and also as a member of the Committee on Advertising, the Editorial Committee and the Committee on Education. He was an orthopedic surgeon to the Columbia and Milwaukee hospitals and consulting orthopedic surgeon to the Milwaukee Children's Hospital. Dr. Gaenslen was chairman of the Section on Orthopedic Surgery of the American Medical Association, 1924-1925, a member and

past president of the American Orthopedic Association and the State Medical Society of Wisconsin, a member of the American Academy of Orthopedic Surgeons and the Clinical Orthopedic Society, and a fellow of the American College of Surgeons. In his chosen specialty he was widely known for his geniality, his scientific contributions and as an inspirer of young men to high ideals and scientific advancement. He gave freely of his time and his efforts to many public and scientific causes.

**Augustus Warren Crane** Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; fellow of the American College of Physicians; member and in 1916 president of the American Roentgen Ray Society, member of the Radiological Society of North America and the American College of Radiology; honorary member of the London Roentgen Ray Society; past president of the Kalamazoo Academy of Medicine and the Michigan Association of Radiologists; formerly member of the National Research Council; awarded a gold medal in 1921 by the Radiological Society of North America; acting editor of the *American Journal of Roentgenology*, 1917-1918, and later a member of the editorial board; both the University of Michigan and Kalamazoo College conferred honorary degrees on him; chairman of the Kalamazoo county section of the Michigan State Committee of Medical Preparedness and a member of the Michigan Medical Advisory Board during the World War; aged 68; died suddenly, February 20, of coronary thrombosis.

**Frank Yuba Gilbert** Portland, Maine; Medical School of Maine, Portland, 1901; member of the House of Delegates of the American Medical Association, 1914, 1917, 1919, 1927 and 1930; member of the American Academy of Ophthalmology and Oto-Laryngology and the New England Ophthalmological Society; president of the Maine Medical Association in 1928; served during the World War; attending specialist in diseases of the ear, nose and throat at the U. S. Marine Hospital; on the staff of the Maine Eye and Ear Infirmary and a member of the examining board of the U. S. Veterans' Bureau; founder and editor of the *Maine Medical Journal*, 1910-1930; aged 58; died, January 18, in Augusta of heart disease.

**Eugene Kibbey Green**, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; fellow of the American College of Surgeons; member of the Minnesota State Medical Association; president of the Hennepin County Medical Society in 1918; clinical assistant at the University of Minnesota Medical School, 1905-1909, and an assistant in surgery, 1911-1916; on the staff of the Hill Crest Surgical Hospital and the Asbury Hospital; aged 66; died, January 22, in Pasadena, Calif., of coronary occlusion.

**Samuel Kirkpatrick** Selma, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1888; past president of the Medical Association of the State of Alabama and the Dallas County Medical Society; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; aged 71; on the staffs of the Southern Railroad, the Burwell Infirmary and the Vaughan Memorial Hospital, where he died, January 6, of heart disease.

**William Brooks La Force**, Pasadena, Calif.; Chicago Medical College, 1891; fellow of the American College of Surgeons; formerly professor of pathology and gynecology at the Keokuk (Ia.) Medical College and professor at the Tsing Hua College, Peiping, China; formerly on the staff of the Ottumwa (Ia.) Hospital; aged 69; died, Dec. 2, 1936, of injuries received in a fall during a storm, while aboard the liner *President Lincoln*, en route home from Yokohama.

**Orval Melcher Dickerson**, Cairo, Ill.; Jefferson Medical College of Philadelphia, 1910; member of the Illinois State Medical Society; past president of the Alexander County Medical Society; on the staff of St. Mary's Hospital; at one time county coroner; formerly district health officer of Alexander, Pulaski and Union counties; aged 55; died suddenly, January 18, of angina pectoris.

**George Bache Emory** Morristown, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; served during the World War; on the staff of the Morristown Memorial Hospital; formerly on the staff of the Newark Memorial and St. Michael's hospitals, Newark; aged 57; died, January 14, of subacute bacterial endocarditis and *Streptococcus viridans* infection.

**Warren Daniel Miller** Hagerstown, Md.; College of Physicians and Surgeons, Baltimore, 1907; past president of the Washington County Medical Society; on the staff of the Washington County Hospital; aged 56; died, January 16, in the Union Memorial Hospital, Baltimore, of carcinoma of the transverse colon, perforation of the colon and peritonitis.

Article 6. If, as the result of adequate information, the public health authorities consider an individual as probably having a venereal disease, such a person can be required to produce a medical certificate stating that he or she has an active venereal disease or one that is subject to relapse. This notice by the authorities must be kept secret. The certificate can be given only by a physician selected by the patient from an approved list. Other certificates in the same case can be demanded by the authorities at regular intervals. Those of whom such certificates are demanded, must keep the public health (local) officers informed as to their former and present addresses.

Article 7. A jail sentence of from fifteen to ninety days and a fine of from 1,000 to 5,000 francs will be inflicted for any of the following offenses:

(a) Every woman who nurses a child, not her own, if she knows that she has a venereal disease.

(b) Every individual who permits a syphilitic infant, of which he or she is the guardian, to be nursed by any person not its mother, unless a physician has been notified as to the necessary precautions to be taken.

(c) Every individual who knowingly allows a syphilitic infant to be nursed without informing the wetnurse of the existence of the syphilis in the infant.

Article 8. A jail sentence of three months and/or a fine of from 1,000 to 5,000 francs:

(a) For a wetnurse who nurses an infant other than her own, without having received a medical certificate, dating from a period immediately prior to the wetnursing, to the effect that the infant to be nursed is not syphilitic.

(b) For every person who confides an infant to a wetnurse without asking for a medical certificate as in the preceding paragraph.

(c) For every person, except in an emergency, who allows a wetnurse to nurse an infant who is in the charge of said individual, without being sure that a medical certificate has been issued as in the first paragraph of this article.

SECTION 3.—*Examinations and Obligatory Treatment.*—[Note by correspondent: The surveillance of prostitutes is to be taken out of the hands of the morals police and placed in those of the public health authorities. This is hailed as constituting a decided step in advance. There have been many complaints regarding collusion between the "morals" police and keepers of houses of prostitution as well as those engaged in the white slave traffic.]

Article 9. If a tribunal (justice court) has been notified of the fact by the public health authorities that a given prostitute has a venereal disease, the court can order the accused to submit to clinical, bacteriologic and serologic examination, but such person cannot be detained for more than twelve hours.

Article 10. Any person who, as the result of the aforesaid examination, is found to be afflicted with a venereal disease either in an active stage or subject to recurrences, will be obliged to submit to appropriate treatment. The latter must be carried out either in a dispensary or by a physician who is on a list approved by the public health authorities.

Articles 11 and 12. A person, notified of the existence of a venereal disease, who does not agree to be treated as outlined in article 10, will be conducted to a public or private institution in order to be given the necessary care.

Article 13. If, while under treatment, the individual leaves the institution without being authorized to do so, a penalty of from six days to three months of prison will be inflicted.

#### Endometriomas of the Ovary

At the Dec. 2, 1936, meeting of the Académie de chirurgie, two cases of ovarian endometrioma were reported by Brocq and Palmer. They stated that reports of about 100 cases had been published in foreign and only four in French journals.

Endometriomas of the ovary are usually recognized at laparotomy, either no preoperative diagnosis having been made or the tumor having been found during operations for other lesions. In the first of the two cases that formed the basis of the communication, the patient was 24 years of age and her complaints were dysmenorrhea and pain on defecation. On bimanual examination a hard, smooth nodule the size of an almond could be felt in the rectovaginal septum. A preoperative diagnosis of endometrioma was based on the history of pain beginning just before menstruation accompanied by severe pain in the rectum during defecation. At operation, the left ovary containing two large cysts and an endometrioma located beneath the mucous membrane of the posterior vaginal fornix were removed. The second patient was 58 years of age and the history was that of an acute appendicitis which had not been operated on. Six weeks later, when first seen by the authors, a diagnosis of torsion of the pedicle of a right ovarian cyst was made. This was confirmed at operation. Microscopic study of the removed ovary revealed the existence of a benign proliferation of tubules of the endometrial type. Sixty per cent of endometriomas are found in the ovary, quite often in both ovaries and associated with a tumor of the same type, situated in the culdesac of Douglas, as in Brocq and Palmer's first case. Endometriomas are characterized by their tendency to form fairly large hemorrhagic cysts as well as by the rupture, often recurrent, of cysts with tarlike contents accompanied by symptoms like those of a pelvic peritonitis, followed by adhesions. Like endometriomas elsewhere, those of the ovary are found during the period of its maximum activity. In taking the previous history of such patients, one notes the frequency of abortions, genital infections and operations for fibroids or retroversion. In some cases the tumors are latent and are found accidentally during operations for other conditions. In others, however, the symptoms are so marked that a tentative or even positive preoperative diagnosis can be made. Hemorrhages into the cysts occur during menstruation and, in proportion to the increase in tension within the cyst, there is an increase in pain. If the cyst ruptures, the symptoms of a pelvic peritonitis often follow such an incident. After cessation of the menstrual period, the contents of the cyst are absorbed; but all the symptoms recur with increasing intensity at each successive menstruation.

The clinical diagnosis can be made from: 1. A dysmenorrhea appearing late during the menstrual period; this is the most typical symptom of an endometrioma but is not specific for an endometrioma of the ovary. 2. Attacks of pelvic peritonitis during or immediately after menstruation as indicative of the rupture of the ovarian cysts with "tarry" contents. 3. Frequent menorrhagias, when not due to uterine myomas. 4. Primary or secondary sterility, which is almost constantly observed. 5. The physical signs are those of adnexal disease but suspicion should be aroused if the pain increases toward the end of menstruation. Hence it is advisable to make another bimanual examination as soon as possible after the menstrual period. 6. If there is no adnexal mass to be felt, the presence of a small, slightly nodular, firm nodule in the culdesac of Douglas is of frequent occurrence in endometrioma of the ovary. If during a laparotomy one suspects the existence of an ovarian endometrioma, a biopsy is indicated. If a frozen section reveals the presence of the specific microscopic elements of an endometrioma, viz., cylindric epithelium like that of the endometrium, a typical cytogenous chorion and numerous macrophages, it is advisable to remove both ovaries to avoid spread to adjacent portions of the pelvis. If there is danger of injury to the bladder, ureter or intestine during removal of secondary growths, it is better judgment to abandon the attempt to remove all the tumors and to resort to postoperative irradiation to prevent recurrences.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### SENSITIVITY TO BUTESIN PICRATE

To the Editor:—I have recently recovered from a severe dermatitis of my face which I believe due to butesin picrate, which I had been using on a patient at the time. Will you kindly inform me as to the frequency of this particular sensitivity and whether this dermatitis occurs in any particular form? Is there any method of desensitization for this and its relative compounds or must contact be carefully avoided? Please omit name.

M.D., New Jersey.

ANSWER.—Butesin picrate ointment is frequently applied to denuded areas of skin; it is especially used to cover burns, including sunburn. It is a chemical combination containing 63 per cent butesin (dinormalbutyl-*p*-aminobenzoate trinitrophenol) and 37 per cent trinitrophenol (picric acid). It was placed on the market about 1926 and in 1929 Pusey and Rattner (*Arch. Dermat. & Syph.* 19:917 [June] 1929) reported the first case of dermatitis from butesin picrate and stated that they knew of two other susceptible individuals. Their patient applied the ointment to skin burned by a mustard plaster and immediately the dermatitis was intensified. An acute weeping vesiculobullous eruption was present for several days and cleared when the ointment was stopped and 0.5 per cent aluminum acetate solution was applied, followed by a cold cream containing zinc oxide. The dermatitis reappeared one week later when the patient put on the dress worn the first time the butesin picrate ointment had been used. On removal of the dress and similar treatment as before, the dermatitis cleared up quickly. Patch tests with butesin picrate were refused by the patient.

In 1930 Jackson (*Arch. Dermat. & Syph.* 21:40 [Jan.] 1930) reported five cases of dermatitis, two due to butesin picrate ointment and three to trinitrophenol solution. In one of the patients sensitive to trinitrophenol, a nurse who handled this in the operating room and who was cured by removal from contact with the acid, a patch test with trinitrophenol was followed quickly by a severe local and generalized erythematous and vesicular eruption, which did not heal for several days. One of the patients had a severe and prompt eruption, also erythematous and vesicular, following the use of butesin picrate ointment for itching hemorrhoids; a secondary eruption followed in two or three days.

Kelly (*Kentucky M. J.* 30:516 [Sept.] 1932) reported four more cases due to butesin picrate ointment, two applied by the author and two self applied. In one patient, a woman of 26, the ointment was used for a burn of the fingers and reapplied daily for three days. An acute weeping vesiculobullous dermatitis resulted, with marked itching and burning. After the skin had healed, a patch or contact test was applied to a clear area of the skin and ten hours later an erythematous vesicular eruption 3 inches wide developed; the next day the lesion was one huge bulla. Kelly points out that butesin picrate ointment may be very treacherous and advises preliminary patch testing when the ointment is to be applied extensively. He also states that there are many cases of dermatitis from an alcoholic solution of trinitrophenol used in preparing the operative field; watery solutions are not so irritating.

Also Fox (*Arch. Dermat. & Syph.* 26:44 [July] 1932) told of a laborer whose abrasions of the leg were treated by butesin picrate ointment. That night there was considerable burning and itching, and during the next few days the skin of a large part of the body became inflamed and scaly and the patient was hospitalized. Later a patch test with the ointment was followed by a severe local erythema and vesiculation, which lasted several days.

Sulzberger and Wise (*Arch. Dermat. & Syph.* 28:461 [Oct.] 1933) discussed the subject fully and reported four additional cases of dermatitis due to butesin picrate. These were similar to those already quoted with the exception that in the first patient the ointment was applied to a burn on the arm each day for one week; the dermatitis began one week after the ointment had been stopped and was associated with marked edema of both arms; the site of the burn was not involved. Ten days later a severe pruritus developed all over the body, and healing was not complete for two months after the ointment was stopped. Patch tests were strongly positive for butesin picrate ointment and also for 1 per cent butesin solution in alcohol.

Tests were negative for trinitrophenol, 1 per cent solution benzoic acid and 1 per cent solution salicylic acid; there was a mild positive reaction to 1 per cent ethyl aminobenzoate solution. In their second case, dermatitis began ten days after the use of the ointment had been stopped; again the site of the burn was spared. Patch tests were positive for both the butesin picrate ointment and 1 per cent alcoholic solution and also for trinitrophenol. In the third case dermatitis developed ten days after the first application of butesin picrate ointment. Patch tests were again strongly positive for all three and were followed by a severe generalized dermatitis, which lasted ten days. In the fourth case a severe generalized dermatitis followed application of butesin picrate ointment for pruritus vulvae; patch tests were strongly positive for the ointment and the skin did not heal for three weeks.

Sulzberger and Wise point out that in eczematous drug eruptions the epidermis is probably the seat of sensitivity, the reaction is a dermatitis eczematosa, and contact or patch tests are of great aid. They believe that the title "dermatitis eczematosa due to drugs" is correct, as it does not imply a certain manner of contact and thus includes all eczematous drug eruptions, whether the drug reaches the skin from without or from within. They also state that butesin leads to a follicular eruption with marked edema and pruritus and little erythema; the rash persists several weeks. Trinitrophenol, they state, causes a diffuse and often severe erythema with vesiculation that desquamates and heals quickly. They believe that their cases showed not only a dermatitis venenata, resulting from external contact, but also a dermatitis medicamentosa due to absorption and hematogeneous distribution, thus explaining the secondary widespread pruritus and dermatitis.

Josef Jadassohn (*Zur Kenntnis der medicamentosen Dermatosen*, Vienna, Wilhelm Braumüller, 1896) was the first to employ patch tests, and Bruno Bloch (*Arch. Dermat. & Syph.* 19:175 [Feb.] 1929) has shown that all drugs that lead to an eczematous and vesiculating type of eruption can usually be discovered by patch or contact tests.

These cases illustrate the fact that dermatitis from butesin picrate ointment is not infrequent, that an alcoholic extract of trinitrophenol may also cause a dermatitis in susceptible individuals, and that patch or contact tests should be done cautiously because generalized reactions may follow. A few hours' exposure at most is sufficient. That dermatitis from butesin picrate is infrequent is indicated by statistics from the Inland Steel Company showing that a dermatitis develops in only about one in 6,000 cases.

The treatment consists of prompt removal of the ointment; it may be advisable to wash out the area with olive oil or liquid petrolatum. Any soothing application may follow. Attempts at desensitization have not been reported; avoidance is usually quite simple. In susceptible individuals, many substitutes are available.

### BLOOD COAGULATION TESTS BEFORE TONSILLECTOMY

To the Editor:—Please give a brief general discussion of clinical methods of reducing bleeding and clotting times as applied to the individual who is not suffering from any detectable disease. Is it advisable to do routine bleeding and clotting tests preceding tonsillectomy? When either of these times is found to be prolonged, what steps should be taken? Is any preparation given orally after the operation of value in stopping post-tonsillectomy bleeding? Is calcium by mouth helpful? Is ceanothyn by mouth effective? Have any of the commercial injection products been proved effective? Please omit name. M.D., New York.

ANSWER.—A discussion of prolonged bleeding and clotting time in what appear to be otherwise normal persons would not be complete unless the method of determining the bleeding or coagulating time is taken into consideration.

By bleeding time is meant the time necessary for a small cut to stop bleeding. The mechanism involved in this cessation of bleeding includes among a number of factors those pertaining to capillary permeability, substances in the tissue juices and the blood platelets. The size of the incision, squeezing the site, and so on affect the amount and character of the tissue juices and hence interfere with the reliability of the test.

By coagulation time is meant the time required for blood withdrawn by one method or another to coagulate in vitro. The ordinary capillary tube or watch crystal or glass slide methods are not reliable because of the variable factors due to evaporation, to squeezing the cut region to obtain an adequate amount of blood (thereby adding additional tissue juices), and to the difficulty of getting absolutely clean glassware. The best manner of determining coagulation time is by some method such as Howell's, wherein an amount of blood is withdrawn by needle and syringe from a vein and allowed to stand in a test tube until a clot is formed. The time required depends on the

relieved. Vincent has already carried out a procedure to relieve pressure in twelve cases. The astonishing thing about the therapeutic course of these cases was that as soon as the compression was relieved the menacing general symptoms (cachexia, anorexia, vertigo and headache) completely disappeared and a distinct period of convalescence began. So extensive was the subjective improvement that the patients felt themselves cured. No indication of a cerebral process could be detected from a neurologic-objective standpoint in some of the cases, despite the fact that the abscess was still present.

To relieve the pressure it was not necessary to open the dura but merely to effect a more extensive fenestration of the *sinciput*. Puncture of the abscess was performed only in those cases in which the abscess itself by its great extent gave rise to the phenomena of compression. As soon as the formation of a regular abscess membrane had taken place (generally within three to four weeks) the abscess in toto was extirpated at a second intervention. By this method the danger of a meningitis produced by the purulent discharge from the opened abscess is avoided. In the majority of cases the cranium can then be closed without drainage; the wounds heal nearly always by first intention. Only one of the twelve cases ended fatally, whereas it was possible to bring all the others to recovery.

After commenting on Vincent's report, Albrecht added that on the basis of experiments at the neurologic clinic of Berlin University a precise localization of a cerebral process was almost unexceptionally to be undertaken. Albrecht cautioned against the dangers of encephalography and pointed out the significance of alterations in the cerebrospinal fluid, such as the increased number of cells, the increased protein content and the alterations in the curve in the colloidal gold test.

Sauerbruch laid strong emphasis on the fact that an acute cerebral abscess may exhibit all the signs of a typical inflammation in other organs. In abscess cases an expeditious drainage of the pus is indicated, particularly if phlegmon and meningitis are manifested. Hence Vincent's procedure, while not to be depreciated, ought unqualifiedly to be confined to those chronic cases in which the suppurative foci tend to encapsulate.

#### Data on the Misuse of Soporifics

Since about 1925 an increase in the misuse of soporific drugs has been noted and latterly some interesting data in this connection have been made public.

Pohlsch and Panse have collected extensive illustrative statistical material with regard to the situation in Berlin, where single cases of poisoning from the use of soporifics increased fourfold between 1925 and 1932. Observed cases of chronic misuse of these drugs increased eightfold during the same period. By 1932 the misuse of soporifics had already become as prevalent among women as addiction to morphine and considerably more prevalent than alcoholism. There were an increasing number of reports of deliriums and hallucinations following chronic abuse of sleep-producing drugs; especially common were cases of phanodorn psychoses. One case of status epilepticus was reported which terminated fatally during a phanodorn delirium. The trend seems to have continued through 1934. On the basis of these data it was concluded that the number of soporifics is too great and that fewer of them ought to be prescribed.

Certain data are available also from the district covered by the psychopathic hospital at Bonn. Schubert reports that the number of habitual addictions to soporifics has steadily increased since 1929. Their percental proportion of the average total of 1,100 patients at the Bonn institution amounted in the years from 1925 to 1929 to zero, but up to 1935 it had risen steadily to 1.1 per cent and had therewith already exceeded the percentage of morphine addicts, which was 0.7. From Jan. 1, 1929, to Nov. 1, 1936, thirty-seven cases of chronic misuse of sleeping drugs were recorded. These were distributed accord-

ing to the drug misused as follows: phanodorn, thirteen cases; phenobarbital, five cases; barbital, three cases; bromural, two cases; one case each involving respectively allonal, noctal, chloral hydrate and optalidon, and finally ten cases in which more than one medicament was misused. Psychotic manifestations, after addiction of long duration, took place in ten of the thirty-seven cases and in each of these ten cases the symptoms assumed an aspect of delirium. There were five such cases among the thirteen phanodorn addicts alone. One of the latter died during a psychotic state from subacute yellow atrophy of the liver. It is worth noting that in four cases manifestations of phanodorn delirium were preceded by epileptic attacks.

#### Interval Between Onset of Symptoms and the Beginning of Treatment in Mental Disease

Medical statistics supply as a rule only summary data and do not permit the course of a disease adequately to be considered in its chronological aspect. The sick insurance groups have an economic interest in such information, especially as it bears on the length of time spent in hospital and incapacity for work. Accordingly they have established bases for estimating these things. Data on the duration of a disorder prior to the initiation of regular therapy are of importance. Despite the difficulties incident to such an undertaking, Dr. Pohlen of the German national health bureau has attempted an evaluation of the periods of time that elapse between the manifestation of the initial symptom of mental disorders and the beginning of asylum care. He has worked out a method for the determination of this average interval. Because of the individual character of mental cases, the clinical beginning of the disorder must, for purposes of statistical evaluation, be considered to date from the day on which the first symptoms were plainly manifested. Hence, what Pohlen has essayed is not a true delimitation of the course of mental disease but only an estimate of its duration as manifested externally; namely, from the onset of symptoms to the beginning of institutional therapy. His conclusions may be summarized as follows:

In idiocy and imbecility, the initial symptoms are generally in evidence at a relatively early age. The condition of more than 50 per cent of male and nearly 50 per cent of female idiots and imbeciles is diagnosed before the end of the fifteenth year of life. Feeble-mindedness is usually determined somewhat later (2.4 years on the average) among women than among men. Likewise the time at which the first institutional treatment is initiated is about one year later for women than for men. The average interval between the onset of symptoms and the initial treatment at an institution is 12.5 years for men, 11.2 years for women. It is worthy of note that among women over the age of 60 no first symptoms are manifested nor is any first institutional care introduced. The great preponderance of idiots and imbeciles are persons in the younger age groups.

In cases of insanity on a constitutional basis, the sexual variation between the corresponding time interval is slight enough, only 3.9 years for men and only 3.2 years for women. In manic depressive insanity the intervals are 3.1 years for men, 2.6 years for women.

In paranoia (paranoic reactions and paranoic development) the mean interval is comparatively small: 3.2 years for men, 6.5 years for women.

Dementia praecox is a strongly marked disease of younger persons between the ages of 15 and 35. The average interval is here relatively brief: 3.5 years for men, 3.7 years for women.

In epileptic insanity the average interval amounts to 8.8 years for men, 13.6 years for women. It is to be remarked that the first symptoms of this disease are observed in women earlier by an average of 6.5 years than in men.

In insanity based on syphilis, the average interval for men is only 1.1 years, for women 2 years. The distribution accord-

continuance of urinary shreds, however, the irrigations are stopped usually after the first four or six weeks. The patient presents himself with urine in his bladder, passes a small quantity in one glass, has his prostate massaged, and passes the rest of his urine. If microscopic study of the prostatic secretion does not show a steady decrease in the number of pus cells per high power field, the patient is searched for tooth or tonsillar infections to make sure that the residual prostatitis is not of focal infective origin. The proofs of cure are those generally employed for any type of treatment.

#### COPPER POISONING IN INDUSTRY

*To the Editor:*—Certain patients (who are under my care) with the complaints of burning and soreness of the eyes and irritation of the throat are exposed to dust particles in the air composed primarily of cuprous oxide. This dust results from the use of cuprode in greenhouses to prevent fungous diseases of plants. I would appreciate any information you can give relative to the irritation factor or danger in using cuprous oxide.

M.D., Illinois.

**ANSWER.**—This reply deals with cuprous oxide in general and not with any particular trade brand. Although the copper ion is toxic, systemic copper poisoning in industry is either nonexistent or occurs with rarity. Several occurrences of so-called copper poisoning later have proved to be attributable to arsenic, lead or other toxic metals associated with the copper. This applies to some dermatoses attributed to copper which with greater likelihood may have been produced by arsenic. On the other hand, some skin disorders properly have been traced to copper as the source. Green discoloration of the skin and hair frequently arises among copper workers in various trades. So far as is known, this condition constitutes no proof of damage from copper. Various copper salts and other compounds, including cuprous oxide, have been associated with mild dermatosis as the cause. In the case of cuprous oxide it appears that exposure to this substance in very minute particle size leads to greater irritation than from the same salt in larger particle ranges. Conjunctivitis has been observed. Also, inhalation of cuprous oxide in fine powder is known to induce low grade respiratory tract inflammation. These conditions have appeared among workers treating the hulls of ships with copper salts for the purpose of repelling parasites that otherwise might attach themselves to the ships. In greenhouse work, common practice makes use of several fungicides and insecticides. In addition, various plants found in some greenhouses may give rise to the symptoms mentioned in this query through allergic action. If these other possibilities can be eliminated, it becomes reasonable to regard the cuprous oxide as the source of the inflammation described. Even so, the condition produced is not of a serious nature, so far as is known, and speedily clears up on the cessation of exposure.

#### PATHOLOGY OF EIGHTH NERVE DEAFNESS IN CONGENITAL SYPHILIS

*To the Editor:*—What is the pathology of eighth nerve deafness in congenital syphilis? In the literature and in books on this subject, the following factors have been cited: a localized meningitis, disease of the labyrinth itself, periostitis and osteitis of the bony labyrinth. Please omit name.

M.D., California.

**ANSWER.**—A pregnant woman suffering from active (secondary) syphilis may deliver prematurely, or if she goes to term the child may be stillborn. If the child is born alive its chances for survival are much impaired. In each of these instances severe active secondary syphilis in the fetus or infant is common.

The temporal bones of such children have been studied by a number of investigators. The pathology appears to be part of a generalized syphilitic meningitis and involves the membranes about the eighth nerve. They are furthermore involved as they dip inward with the perineurium to divide the nerve into bundles as far even as the endoneurium (Mackenzie).

The spirochete in addition to its presence elsewhere has been found between the nerve fibers, in the periosteal dural sheaths as far as the porous acusticus internus, and also in the acoustic ganglion.

The syphilitic infiltration may also involve the labyrinth. Such children, if they survive and are deaf, will present signs of inner ear or auditory nerve type. The static labyrinth is, as a rule, involved in these cases also and is not excitable.

There is another form of congenital syphilitic involvement of the inner ear wherein the evidences of syphilis are absent at birth but become manifest from five to twenty years later. The parents, or the mother at least, at the time of birth suffered from a later form of syphilis than in the first type of case.

Along with the deafness, these children manifest other signs of hereditary syphilis; i. e., one or more of the stigmas of Hutchinson.

Pathologic studies in this group of cases have been infrequent. Mayer reports two cases and states that only three others have been thoroughly studied. He classifies changes presented as (1) osteomyelitis gummosa, (2) periostitis gummosa and (3) syphilitic periostitis productiva (nongummatous).

Among the special sites of involvement are the cochlea, in which military gummas may be seen in the endosteum of the scalae and the ligamentum spirale.

The semicircular canals may be the site of a productive periostitis; subperiosteal gummas are seen in the internal meatus, and the auditory nerve may become atrophied as the result of round cell infiltration.

The bony capsule of the labyrinth may be the site of a diffuse osteomyelitic process leading to defects and erosions of the capsule.

#### CARDIOVASCULAR INJURY AFTER ELECTRIC SHOCK

*To the Editor:*—A man, aged 56, was rendered unconscious eighteen months ago with an electric charge having a voltage of about 750, coming from a radio amplifier. He was unconscious about fifteen minutes, apparently recovered, and then went into symptoms of collapse, difficult breathing and cold perspiration. A condition developed which the family physician called "threatened pneumonia." This lasted ten days. Burns of both hands took three months to heal. Pains in the chest have never left him; they are worse on deep breathing. The arms tire easily; he cannot hold a cup of tea early in the morning. X-ray examination of the chest and abdomen is negative; a cardiograph is negative; the reflexes are normal or slightly overactive; the patient's sexual life is normal; the Wassermann reaction of the blood and spinal fluid is negative. The patient was exceptionally active and athletic and healthy previous to the accident. At present there is marked clubbing of the fingers; the condition of the suspended hand is nearly cyanotic, with blanching of the elevated one. The pulse with the patient resting is 80. After twice squatting and twice touching his toes, the patient has marked labored breathing but the pulse is elevated to only 84. The hands are always clammy. The blood pressure is 160 systolic, 90 diastolic. The temperature is 98. There are marked "habit spasms" of the muscles of the face. Could the electric current have caused capillary changes to account for the clubbing of the fingers, or could there have been damage to the autonomic nerve fibers of this part of the body which might cause the circulatory disturbances noted? At present the condition seems permanent and is disabling. Can you suggest treatment? What other information can you give me regarding results of electric shock of this type. Please omit name.

M.D., Canada.

**ANSWER.**—Cardiovascular damage following electric injuries in some measure depends on the path traversed by the electric current, particularly if the brain is included. High blood pressure is more likely to follow electrical accidents involving injury to the vasomotor centers in the brain. Ventricular fibrillations in nonfatal accidents more commonly arise when the brain was not included in the route of the current. In the vicinity of local electrical burns, direct damage to the blood vessel walls may account for circulatory disturbances during and after the healing process. In the present instance, it is inferred from reference to burns on both hands that the course of the current did not include the head. Nonfatal accidents in which ventricular fibrillation reflects the injury to the heart are more often associated with low tension current as in this case. However, both high and low tensions may lead to fibrillation. The alternating current is much more dangerous than the direct. It is believed that, in as many as 90 per cent of fatal accidents, cardiac fibrillation takes place whether or not this is recognized. The nature of the persistent damage in the heart may best be determined by electrocardiographic examination. In animal experiments, fibrillation following electric shocks has been successfully treated through the administration of potassium chloride. Little use of this drug has been made in connection with human cases. In part this is due to the lack of availability at the time of direful electrical accidents; in part, however, it is due to the recognition that potassium chloride in itself is a dangerous agent.

The clubbed fingers mentioned in the query are commonly associated with a variety of cardiac lesions unrelated to damage from electricity, but conceivably they might be associated with chronic cardiac damage inaugurated by electrical injury.

lactic measures of a hygienic character, including cotton masks for the medical staff and patients with light forms of infection, and physical therapy and ultraviolet irradiation to raise the protective forces. Methenamine and quinine in small doses possibly are effective as a prophylactic. For the treatment of colds the meeting recommended rest in bed, symptomatic therapy, methenamine, salicylates and quinine preparations in various combinations.

### BUENOS AIRES

(From Our Regular Correspondent)

Feb. 13, 1937.

#### Politics in Scientific Matters

Dr. C. Robertson Lavalle has treated, for a long time, tuberculosis of the bones by means of implantation of a graft, which is taken from the tibia or the fibula. He used to make a perforation at the spot corresponding to the main tuberculous focus, followed by implantation of the bone splint in the area left by the perforation. According to Robertson Lavalle, the implanted bone splint stimulates the local circulation, which induces healing of the tuberculous lesion. Robertson Lavalle applied the method also with the same technic to pulmonary tuberculosis. He has modified his technic and with a trocar perforates ocular, peritoneal, laryngeal, lupus, pulmonary and bone tuberculosis with the aim of opening the main tuberculous focus. Dr. Lavalle is at present professor of surgical pathology in the Faculty of Medicine of the University of Buenos Aires and an elective member of the board of directors of the faculty. The board is an administrative body. Nevertheless he asked Dean Arce, who belongs to the same political party in the university, to request from the government the creation of a surgical clinic for application of his method. Dean Arce appointed a committee made up of Drs. R. Argañaraz, R. Donovan, E. Castaño, J. A. Saralegin, A. B. Zambrini, L. Facio and C. Fonso Gandolfo to study the method and give an opinion as to its value. The members of the committee reported that the method is harmless and of a simple technic and also that it gives satisfactory results. The faculty asked the executive branch of the government for the creation of a clinic of surgery under direction of Dr. Lavalle. A deputy presented the same project to the house of representatives. The majority of physicians are of the opinion that scientific matters should be solved through discussion in scientific centers rather than through political influences.

#### The Construction of a New Medical School

Dean Arce of the Faculty of Medicine of the University of Buenos Aires, and a deputy, presented a project to the house of representatives for construction of a new clinical hospital and a new building of the Faculty of Medicine on three of the four blocks which belong to the university. The project was neither approved nor rejected in the house but left for a further study. Dr. Arce asked then the approval of his project by the executive branch of the government, which approved it. The buildings of the clinical hospital and of the Faculty of Medicine will be demolished. One of the lots will be made into a public garden and the other will be for the construction of a building for the National Library. Dr. Arce's idea of demolishing the faculty before constructing the new building met with general opposition. A board of ten architects was appointed and they were asked to present plans within thirty days for construction of the buildings. According to general opinion, the time given to the architects for the preparation of the plans is short; they need more time to present acceptable plans, and the opportunity to share in the plans should be given to all and not just a few of the architects in Buenos Aires. Of the preliminary architectural plans for the building of the Faculty of Medicine, the one that obtained the prize

called for a nineteen story building, whereas after that the height of the building was limited to 40 meters. The School of Odontology, on the other hand, will be a nineteen story building and will have more than twenty lecture rooms. By the projects presented to the government the expense of constructing the building of the Faculty of Medicine and the polyclinics will be 100,000,000 pesos (\$27,000,000). Many editorial articles have been published in the press against the project. The house of representatives, in approving the bill, allowed a total amount of 25,000,000 pesos (\$7,000,000) and asked for new plans which should be presented before July of the present year. The plans ordered by the faculty will deal with 4,000 students in the Faculty of Medicine and 3,000 students in the School of Odontology.

#### A New Curriculum—Teachers Reduced

The new plan for medical studies was recently approved by the Faculty of Medicine. The entire course will cover seven years. The basic cycle includes histology and anatomy in the first year, physiology in the second and parasitology in the third. The preclinic cycle includes semeiology, pathologic anatomy and microbiology in the fourth year and pathology, surgery, toxicology, pharmacology and therapeutics in the fifth year. The clinic cycle includes clinical work in medicine, surgery, pediatrics, puericulture, obstetrics and nutritional diseases, as well as orthopedics, otorhinolaryngology, ophthalmology, dermatosyphilography, neurology, urology, gynecology, roentgenology, physical therapy and legal medicine. The faculty complains of lack of funds. For this reason the number of teachers was cut down 43 per cent. Nevertheless new chairs have been created. There were two teachers of obstetrics and two of semeiology. There are now four for each of the subjects. There are also a chair for teaching of nutritional diseases and four assistant professors of surgical semeiology. Two new chairs for teaching neurosurgery and the history of medicine are going to be established in the near future. The school of odontology recently established six chairs and will have in the near future two more chairs for teaching metallurgy and surgery of the mouth.

## Marriages

---

CHARLES DANE, South Orange, N. J., to Miss Madeline Louise Noyes of Arlington, Mass., Dec. 21, 1936.

ANTHONY RUPPERSBERG JR., Columbus, Ohio, to Miss Adele Isabel Gustites of Philadelphia, Nov. 26, 1936.

JOHN STEPHEN CLEMANS, Gloversville, N. Y., to Miss Alice Ryder Durham of Norfolk, Va., Dec. 5, 1936.

ALBERT McCANDLESS, Sylvan Lake, Mich., to Mrs. Emma Mae Chapman of Manatee, Fla., Dec. 2, 1936.

CORNELIUS S. FRANCKLE, St. Petersburg, Fla., to Miss Ruth Travers of Millville, N. J., Dec. 26, 1936.

WILLIAM H. FLYTHE, Norwood, Ohio, to Miss Doris Elizabeth Fenner of Plymouth, Dec. 25, 1936.

LEE EDWARD FARR, New York, to Miss Anne Minerva Ritter of Beverly Hills, Calif., Dec. 28, 1936.

CLARENCE PAUL CAMERON, Fayetteville, N. C., to Miss Vivian Lebo of Elkton, Md., Dec. 24, 1936.

EDWARD PARKER DENNIS to Miss Mildred Torrance, both of Erie, Pa., February 21.

MATHEW R. FURMAN to Miss Juliet Blume, both of New York, Dec. 24, 1936.

MILTON H. MILLER to Miss Regina Goldman, both of New York, Dec. 6, 1936.

JAMES J. COLLINS to Miss Alice Connor, both of Galena, Ill., January 4.

LOUIE T. CARL to Miss Dora Bishop, both of Memphis, Tenn., Dec. 19, 1936.

## LATENT GONORRHEAL INFECTION

*To the Editor:*—A married woman, aged 33, of excellent habits, was infected with gonorrhea by her husband at 21 years of age. She had a stormy time, lasting eight weeks. The adnexa were affected early, accompanied by a profuse discharge, high temperature and pulse, and extreme lower abdominal pain, particularly on the left side. Following the abdominal acquiescence she was treated for a time and pronounced apparently cured. In the intervening twelve years she had two or three mild flareups, consisting of lower abdominal pain of short duration. During each of these attacks she was examined by a competent gynecologist and pronounced free from any palpable abdominal masses. The past attack dates back five years. During these years she has never conceived; she suffers severe sick headaches either before, during or after her menstrual periods, which are regular, of the twenty-eight day cycle, lasting six days, with little, if any, abdominal pain. About July 7, 1936, she noticed a slight vaginal discharge. As this was five days before her menstrual period, I attributed the discharge to it. July 12, the first day of menstruation, she waded into the ocean and was struck by a wave just high enough to wet her as high as the lower part of the abdomen. The following day she developed pain in the lower part of the abdomen. Whether there was a vaginal discharge she could not tell, menstruation having been fully established by this time. I first saw her July 20, at which time the pain and tenderness were extreme, aggravated by walking or riding in trolley cars. The vaginal discharge was profuse. There were no chills or fever. Bimanual examination was out of the question on account of the pain. However, a cervical smear was obtained very gently and proved positive for gonorrhea. So was a urethral smear. Granted that this condition is not the result of a recent infection acquired extramaritally, and I have good reason to believe it is not, would you kindly render an opinion as to the probable cause. Could a flareup of the twelve year old infection manifest itself at such a late date in just such fashion as described, with no apparent exciting cause? Could her husband have reinfecting her, having himself been a carrier? And could she have been reinfecting by the same man, by the same species of gonococci, granting, of course, that he himself has not been recently infected? Please omit name and address.

M.D., Pennsylvania.

*ANSWER.*—In histories such as described, it is found most commonly that the husband has a recent infection, and when the patient has had a previous infection there may be little or no urethral discharge and the centrifuged sediment of the urine, as well as the prostatic secretion, should be examined for gonococci. It is not stated whether the husband has had such an examination.

There are instances in which it is reasonably certain that the infection is not acquired extramaritally, but it is possible in extremely rare instances that there might be an accidental infection through an intermediate exudate even though it is not generally accepted as a source of infection in the female after puberty.

As regards the duration of the carrier state, it is becoming increasingly evident that such conditions persist longer than is generally supposed but seldom longer than two years in an individual who has remained continent, although there have been instances reported of exacerbation of active clinical infection after twenty to thirty years. In the instance cited, assuming that neither husband nor wife has had an extramarital exposure, it would seem likely that both parties have had a subclinical infection during a greater part of the twelve year period, each infecting the other at intervals frequent enough to prevent cure in both parties. Therefore, unless the husband has recently become spontaneously cured, there should still exist a subclinical or latent infection, and it is advisable that he have a careful examination, including smears, cultures and the complement fixation test.

## EFFECTS OF DISSIMILAR METALS IN TOOTH FILLINGS

*To the Editor:*—A source of endless inquiry by patients concerns effects of dissimilar metals in teeth. To me it seems mostly nonsense. Please give the public and me a chance to meet this kind of stuff authentically. Please omit name.

M.D., Louisiana.

*ANSWER.*—It has long been suspected that dissimilar metals in the mouth in the presence of an electrolyte such as saliva result in the generation of small electric currents, which probably constitute a source of irritation to the oral mucous membranes. Recent observations, both clinical and experimental, tend to confirm this view. It has been noted that localized patches of leukoplakia have formed exactly opposite two teeth containing fillings of dissimilar metals. Actual changes in electrical potential has also been observed in such patients by fine measurements. Clinical and experimental evidence, therefore, combine to cast suspicion on the presence of dissimilar metals in the mouth in relation to oral cancer. If further studies prove this to be correct, it will be established that this is only one more form of irritation. Much more research will

be required to confirm these observations and to determine the precise rôle of this factor in the genesis of precancerous and cancerous lesions of the mouth.

## CHRONIC INDURATED SWELLING OF LIP

*To the Editor:*—A woman, aged 45, has a hard indurated swelling of the upper lip and the nose. She has had it since girlhood and it seems to be getting worse as she grows older. Often the swelling extends into the cheeks. She has a low-grade fever whenever the swelling is present. It comes and goes, lasting from two to three weeks at a time. She had all her upper teeth extracted and there has been no relief. I feel that the condition is due to some disturbance of the lymphatics. What causes the condition and what can I do about it? I have suggested rest and hot or cold application of epsom salt. In the past it has been diagnosed as erysipelas, but I do not think it is. Please omit name.

M.D., California.

*ANSWER.*—The symptoms might be due to a number of conditions. Among these might be considered chronic infection of some of the sinuses of the nose, particularly the ethmoid sinus, which could be determined only by a competent specialist. Roentgenograms are usually quite satisfactory in ruling out infection of the other sinuses except the sphenoid.

It is quite possible that it is recurring erysipelas, in which case one should be able to obtain a streptococcus from cultures of the nose or skin around it. Since this is associated with a lymphangitis, it would be a very probable cause. Immunization through the use of the toxin has proved of value but should be done by one expert in the preparation and dosage of the toxin. Stock preparations might be tried if a streptococcus should be found to be the cause.

Because of the associated fever and course of the attacks, it is not likely that it is due to an angioneurotic edema. However a vasomotor disturbance from infection, external irritant or ingested foods that produce an allergic reaction should be considered. The use of epinephrine, the nitrites and some calcium preparation might be tried. A complete blood count during an attack would help in determining an infectious origin.

## LIPOID METABOLISM—XANTHOMATOSIS

*To the Editor:*—A white man, aged 51, with no knowledge of any constitutional disease and no gout, born in Pennsylvania of German-English ancestry, has been a bank clerk since leaving school, living a sedentary life with little inclination to get much active exercise. He has always enjoyed large quantities of rich food. Alcohol, tobacco, tea and coffee have been used in limited quantity. Twenty years ago he had a tumor back of the right eye and within the lower part of the skull. It was treated surgically and left a discharging sinus for many years. This tumor was benign and believed to have been the result of a cerebral blood clot. During the past fifteen years he has had attacks of painful joints of the feet and elbow, repeatedly diagnosed as rheumatism. He is married and has a healthy daughter and son. Formerly he was rather corpulent, weighing from 205 to 221 pounds (93 to 100 Kg.) but during the past six months he has lost weight down to 185 pounds (84 Kg.). The blood counts are normal, the blood sugar is normal and the uric acid of the blood ranges from 5 to 7 mg. per hundred cubic centimeters. The blood pressure is 210 systolic, 155 diastolic. The left side of the heart is hypertrophied. The patient has arteriosclerosis, a high grade albuminuria, a dry parched mouth and throat, attacks of gastric distress, and tumors over the metatarsal joints, tendon sheath, right index finger and left elbow. The tumor of the left elbow joint was removed and found to contain cholesterol instead of the expected sodium urate. Roentgenograms of the feet, hands and elbow show areas of rarefaction believed to be sodium urate infiltrations. The pathologist further reported that the elbow tumor is an instance of xanthoma nodosum multiplex. The patient suffers greatly from insomnia, attacks of abdominal distress and dyspnea. Treatment has consisted of rest, fluids, salines, a low purine diet, and morphine when required for gastric and abdominal distress. Could there be both a faulty metabolism of fats and nucleoproteins? Is it possible that this condition has resulted from a lack of an internal secretion similar to the insulin of the pancreas in diabetes?

ARTHUR R. RIKLI, M.D., Naperville, Ill.

*ANSWER.*—The finding of a high blood uric acid is indeed suggestive of gout. However, the observation that the tumor removed from the left elbow consisted of cholesterol instead of the expected sodium urate should direct attention to the possibility of one of the diseases of lipid metabolism. Aside from the age of the patient and the length of his medical history, the description is not inconsistent with one of the unclassified essential xanthomatoses similar to Hand-Schüller-Christian's disease. In these conditions there is a widespread deposition of lipid (usually cholesterol esters) containing cells within the bone marrow and widely distributed all over the skeletal system. The skin and the internal organs may be involved to a varying degree. The deposition of the lipid is followed by a granulomatous reaction. It is interesting to speculate whether the tumor removed from the eye and skull

**Wilmer Weir McGrath** • Savannah, Ill.; Central Medical College of St. Joseph, Mo.; 1896; formerly mayor; past president of the Carroll County Medical Society; on the staff of the Savannah City Hospital; aged 67; was found dead, January 9, of injuries and exposure due to a fall on an icy road while going for assistance after his car stalled.

**Louis David Green** • San Francisco; Denver and Gross College of Medicine, 1909; member of the American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; aged 54; part owner of Green's Eye Hospital, where he died, January 14.

**Arthur Winfield Nunnery**, Chickasha, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1916; member of the Oklahoma State Medical Association; past president of the Grady County Medical Society; county health officer; on the staff of the General Hospital; aged 47; died, January 11, of coronary occlusion.

**William N. Johnson**, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1883; served during the World War; aged 78; for many years on the staff of the Germantown Hospital and Dispensary, where he died, January 22, of cerebral thrombosis and bronchopneumonia.

**Thomas Charles O'Connor Jr.** • Lodi, Calif.; University of California Medical School, San Francisco, 1927; past president of the San Joaquin County Medical Society; formerly superintendent of the Bret Harte Sanatorium, Murphy; aged 43; died, January 13, of a self inflicted bullet wound.

**Charles Elder Lindsay**, Chicago; University of Illinois College of Medicine, Chicago, 1914; served during the World War; on the staff of the Illinois Central Hospital; aged 49; died, January 22, of influenza, bronchopneumonia, cerebral hemorrhage and mitral stenosis.

**Thomas G. Burke**, Roanoke, Va.; Medical Department of the University of Alabama, Mobile, 1902; member of the Medical Society of Virginia; aged 59; died suddenly, Dec. 25, 1936, in Richmond.

**Joseph G. Leiter**, Brooklyn; Bellevue Hospital Medical College, New York, 1888; member of the Medical Society of the State of New York; on the staff of St. Mary's Hospital; aged 72; died, January 16, of arteriosclerosis and coronary artery thrombosis.

**Albert Knight Dunlap** • Sacramento, Calif.; Jefferson Medical College of Philadelphia, 1916; formerly superintendent of the Sacramento County Hospital; aged 47; died, January 19, in the Sutter Hospital, of chronic valvular disease of the heart.

**James Edward McIntyre** • Tremont, Ill. (licensed in Illinois in 1891); formerly bank president, mayor, president of the high school board and county physician; aged 75; died, January 14, in the Methodist Hospital, Peoria, of lobar pneumonia.

**Albert Chester Keener**, Altona, Ill.; Northwestern University Medical School, Chicago, 1910; past president of the Knox County Medical Society; aged 63; died, January 10, in St. Mary's Hospital, Galesburg, of injuries received in a fall.

**John E. O'Neill**, Henryton, Md.; University of Maryland School of Medicine, Baltimore, 1910; medical director and superintendent of the Maryland Tuberculosis Sanatorium; aged 62; died, Dec. 31, 1936, of uremia and coronary thrombosis.

**Charles Pomeroy Opdyke**, Verona, N. J.; New York Homeopathic Medical College and Hospital, 1889; member of the Medical Society of New Jersey; aged 74; died, January 21, of cerebral thrombosis and arteriosclerosis.

**Robert Taylor Canon** • Lufkin, Texas; Jefferson Medical College of Philadelphia, 1893; health officer of Lufkin; on the staff of the Angelina County Hospital; aged 69; died, January 2, of coronary occlusion.

**Percy E. Kylo** • Hanover, N. M.; University of Louisville (Ky.) Medical Department, 1911; served during the World War; aged 48; died, January 12, in the Grant County Hospital, Silver City, of pneumonia.

**John James Millmann**, Florissant, Mo.; Beaumont Hospital Medical College, St. Louis, 1900; aged 64; died, January 10, in St. Mary's Hospital, St. Louis, of heart disease, arteriosclerosis and hypertension.

**David W. Jones**, Baltimore; Baltimore University School of Medicine, 1886; member of the Medical and Surgical Faculty of Maryland; aged 74; died, January 17, in St. Joseph's Hospital, of myocarditis.

**A. Ralph Johnstone**, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1887; aged 71; died, January 24, of uremia and malignancy of the bladder.

**Marguerite Gillham Squire**, Carrollton, Ill.; Homeopathic Medical College of Missouri, St. Louis, 1894; county physician; aged 71; died, January 7, of cerebral thrombosis, hypertension and myocarditis.

**Virgil Owen Moore**, Toledo, Ohio; Starling Medical College, Columbus, 1898; aged 67; on the associate staff of the Robinwood Hospital, where he died, January 12, of lung abscess.

**Harry L. Hinckley**, Barnard, Kan. (licensed in Kansas in 1901); past president and secretary of the Lincoln County Medical Society; formerly mayor; aged 77; died, Dec. 23, 1936.

**Frederick L. Darrow**, Brooklyn; University of Maryland School of Medicine, Baltimore, 1910; served during the World War; aged 59; died, January 12, of a cerebral hemorrhage.

**Robert Hardie**, Chicago; Rush Medical College, Chicago, 1901; aged 59; on the staff of the Hospital of St. Anthony de Padua, where he died, January 23, of coronary occlusion.

**John King Farrar** • Audenried, Pa.; Jefferson Medical College of Philadelphia, 1891; aged 69; died, January 19, in Hazelton (Pa.) State Hospital, of bronchopneumonia.

**George Dwight Johnson**, Roanoke, Va.; Maryland Medical College, Baltimore, 1913; aged 48; died, Dec. 23, 1936, of acute cardiac dilatation and chronic mitral insufficiency.

**Minor Harold Day** • Donora, Pa.; Northwestern University Medical School, Chicago, 1902; aged 60; died, January 21, in the McKeesport (Pa.) Hospital, of pneumonia.

**Frances Allen de Ford**, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1887; aged 81; died, January 9, in the Jewish Hospital, of pneumonia.

**William Frank Roper** • Philadelphia; Medico-Chirurgical College of Philadelphia, 1906; aged 53; died, January 12, in the Frankford Hospital, of agranulocytic angina.

**James B. Dudley**, Utica, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1888; formerly a bank president; aged 76; died, Dec. 22, 1936.

**James Larkin Craig**, Webb City, Mo.; Rush Medical College, Chicago, 1914; aged 53; died, January 4, in Peculiar, en route to Kansas City, of brain abscess.

**Joseph Calvin Henderson**, Waelder, Texas; Kentucky School of Medicine, Louisville, 1894; aged 82; died, Dec. 22, 1936, in the Holmes Hospital, Gonzales.

**Anna M. F. Starring**, Pasadena, Calif.; Michigan College of Medicine and Surgery, Detroit, 1896; formerly a practitioner in Detroit; aged 75; died, Dec. 26, 1936.

**William Richard Moore**, Cairo, Ga.; University of Georgia Medical Department, Augusta, 1898; aged 70; died, January 8, in a hospital at Waycross, of influenza.

**Wilbur Lee Davis**, Denver; Gross Medical College, Denver, 1901; county jail physician; aged 63; died, January 2, in St. Anthony's Hospital, of influenza.

**Albert R. Knapp**, Garden City, Kan.; Curtis Physio-Medical Institute, Marion, 1886; aged 85; died, January 2, of a cerebral hemorrhage.

**Thomas B. Bradley** • Philadelphia; Hahnemann Medical College of Philadelphia, 1889; aged 67; died, January 5, of carcinoma of the liver.

**John H. Holke**, St. Louis; Missouri Medical College, St. Louis, 1884; also a dentist; aged 75; died, Dec. 24, 1936, in St. John's Hospital.

**Ezra H. Melott**, Ogden, Iowa (licensed in Iowa in 1886); aged 87; died, Dec. 13, 1936, of cerebral hemorrhage and arteriosclerosis.

**James A. Harvie**, Midland, Ont., Canada; Victoria University Medical Department, Coburg, 1886; aged 74; died, Dec. 20, 1936.

**Archibald McMurchy**, North Bay, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1883; aged 85; died, Dec. 22, 1936.

**Ada Russell Baxter**, Philadelphia; Chicago College of Medicine and Surgery, 1912; aged 73; died, January 16, of myocarditis.

**George Goebel**, Philadelphia; Jefferson Medical College of Philadelphia, 1886; aged 77; died, January 14, of bronchopneumonia.

**Roy Verner Hauver**, Middletown, Md.; Baltimore Medical College, 1904; aged 62; died, January 18, of coronary thrombosis.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

**ALABAMA:** Montgomery, June 22-24. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

**ARIZONA:** Phoenix, April 6-7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

**ARKANSAS:** *Basic Science.* Little Rock, May 3. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular).* Little Rock, June 17-18. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic).* Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

**CALIFORNIA:** *Reciprocity.* San Francisco, May 9. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

**COLORADO:** Denver, April 6. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

**CONNECTICUT:** *Endorsement.* Hartford, March 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

**DELAWARE:** Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

**DISTRICT OF COLUMBIA:** *Basic Science.* Washington, June 28-29 (probable dates). *Medical.* Washington, July 12-13. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

**FLORIDA:** Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

**IDAHO:** Boise, April 6. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

**ILLINOIS:** Chicago, April 6-8. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

**INDIANA:** Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.

**IOWA:** *Basic Science.* Des Moines, April 13. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.

**KANSAS:** Topeka, June 15-16. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

**KENTUCKY:** Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

**MARYLAND:** *Medical (Regular).* Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic).* Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

**MICHIGAN:** Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-204 Hollister Bldg., Lansing.

**MINNESOTA:** *Basic Science.* Minneapolis, April 6-7. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical.* Minneapolis, April 20-22. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

**MISSISSIPPI:** Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

**MONTANA:** Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

**NEVADA:** Carson City, May 3-4. Sec., Dr. John E. Worden, Box 630, Carson City.

**NEW JERSEY:** Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

**NEW MEXICO:** Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

**NEW YORK:** Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

**NORTH CAROLINA:** Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

**NORTH DAKOTA:** Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

**OKLAHOMA:** Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.

**OREGON:** *Medical.* Portland, June 15-17. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science.* Corvallis, July 17. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

**PENNSYLVANIA:** Philadelphia and Pittsburgh, July 6-10. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, Education Bldg., Harrisburg.

**RHODE ISLAND:** Providence, April 1-2. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

**SOUTH DAKOTA:** Rapid City, July 20-21. Dir., Division of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

**VERMONT:** Burlington, June 16-18. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

**VIRGINIA:** Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

**WISCONSIN:** *Basic Science:* Madison, April 3. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical.* Milwaukee, June 29-July 2. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, March 13, page 912.

### Alabama Reciprocity and Endorsement Report

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports 26 physicians licensed by reciprocity and one physician licensed by endorsement from June 26 through Dec. 18, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine.....	(1935, 2)		Georgia
University of Georgia Medical Department.....	(1926)		Georgia
University of Georgia School of Medicine.....	(1934)		Georgia
University of Kansas School of Medicine.....	(1935)		Kansas

University of Louisville School of Medicine.....	(1930)	Mississippi
(1931), (1933) Kentucky		
Louisiana State University Medical Center....	(1934), (1936)	Louisiana
Tulane Univ. of Louisiana School of Medicine.....	(1931), (1935)	Louisiana
University of Minnesota Medical School.....	(1931)	Illinois
St. Louis University School of Medicine.....	(1935)	Missouri
Washington University School of Medicine.....	(1935)	Missouri
Creighton University School of Medicine.....	(1933)	Nebraska
Jefferson Medical College of Philadelphia.....	(1927), (1929)	Penna.
University of Pennsylvania School of Medicine.....	(1934)	Penna.
University of Tennessee College of Medicine..	(1933), (1934)	Tennessee
(1935) Mississippi		
Vanderbilt University School of Medicine....	(1932), (1933)	Tennessee
University of Virginia Department of Medicine....	(1934)	Virginia
Université de Paris Faculté de Médecine.....	(1932)	Texas

School	LICENSED BY ENDORSEMENT.	Year Endorsement of Grad.
Cornell University Medical College.....	(1935)	N. B. M. Ex.

### Florida November Examination

Dr. William M. Rowlett, secretary, State Board of Medical Examiners, State of Florida, reports the examination held in Jacksonville, Nov. 16-17, 1936. Eighty-eight candidates were examined, 60 of whom passed and 28 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1936)		77.2
Yale University School of Medicine.....	(1926) 79.5,	(1932)	77.7
Emory University School of Medicine.....	(1926)		78.7
(1932) 79.1, (1933) 79.3, (1934) 84.8, (1935) 75,			
(1936) 75.7			
University of Georgia School of Medicine.....	(1932)		75.8
(1933) 75.7, 79.2, (1935) 81.5, (1936) 76.4			
Hering Medical College, Chicago.....	(1913)		76.3
Loyola University School of Medicine.....	(1932)		79.5

amount of blood withdrawn and the size of the test tube used. Some methods take from eight to ten minutes, others as long as twenty minutes.

Such determinations, it is clear, do not lend themselves to routine use. The other methods are not completely reliable and hence no standard can be set up. In the last analysis the best safeguard for the surgeon is a careful inquiry into the patient's history, especially as regards the tendency to bleed and an examination to determine his fitness to undergo the operation in question. If the history or the physical examination or carefully conducted bleeding and clotting time determinations bring up any doubts as to the advisability of operation (in this case tonsillectomy), it would be better to postpone the operation as it is seldom one is urgently required, and to proceed further in an attempt to make an accurate diagnosis.

The surgeon's best safeguard against bleeding following tonsillectomy in properly selected cases is to seize and ligate suspicious bleeding areas. He is not to rely on medication given by mouth, hypodermically or intravenously.

The use of calcium by mouth in the customary dosages in individuals apparently normal is probably of little use. There is no reason to believe that the blood clotting mechanism in these people is altered because of a lack of calcium.

Ceanothyn is the name applied to a liquid extractive prepared from the bark of the root of *Ceanothus americanus* (Jersey tea). In 1926 the Council on Pharmacy and Chemistry found Ceanothyn unacceptable for inclusion in New and Non-official Remedies because (1) the composition was uncertain, (2) no tests were furnished to control its identity and uniformity, and (3) no satisfactory evidence for its therapeutic value had been submitted. In 1930 the Council issued a second report on Ceanothyn which concluded that, in consideration of the unestablished and therefore unwarranted therapeutic claims for Ceanothyn, and in further consideration of the inconclusive character of the available evidence for the drug's value as a coagulant, the Council confirmed its decision holding the product unacceptable for New and Nonofficial Remedies.

#### PRECORDIAL PAIN WITH FLUCTUATING BLOOD PRESSURE

To the Editor:—A man, aged 42, has been complaining of frequent periodic attacks of pain in the chest, more often in the left chest over the precordia than in the right, over a period of four years. These attacks were always accompanied by severe headaches, usually frontal and over the right side of the cranium, and a sense of suffocation in the upper part of the thorax, with a fluctuating blood pressure. Taking his blood pressure during such an attack—six or seven times within an hour—would give variations in reading from 160/100 to 120/80. During periods of freedom from attacks, the blood pressure reading is always normal. Physical examination is otherwise completely negative in every detail. Repeated Wassermann, urine, various blood tests, electrocardiogram, and basal metabolism tests were all negative. His teeth, tonsils and appendix have all been removed. Of his past history, he had pneumonia at the age of 7 and gonococcal urethritis at the age of 22. He is a World War veteran. He is well built, well nourished and to all outward appearances a picture of health. What could cause so marked a fluctuation in blood pressure in so short a period of time? Please omit name.

M.D., Massachusetts.

ANSWER.—Pain or fear induced by the precordial pain is an amply sufficient factor to account for the fluctuations in arterial tension as described. Of the two, fear is probably the more potent influence. The effects of emotions on the arterial tension in vasolabile individuals has been repeatedly described (Stieglitz, E. J.: *Am. J. M. Sc.* 179:775 [June] 1930) and a rise of from 40 to 50 mm. of mercury within a few seconds after emotional excitement is not unusual. Coughing, straining or lifting likewise causes transient violent upward fluctuations.

The fact that the patient suffers from recurrent hemicranic headaches along with these attacks of thoracic distress brings the probability of atypical migraine to mind. It is characteristic of the migraine physique (*Am. J. M. Sc.* 189:359 [March] 1935) that the vasomotor apparatus is unusually unstable and that physical manifestations are conspicuously absent. Other evidences of the migraine physique are very fine straight hair, abnormally large pupils (which react normally to light and in accommodation, however), a thin, transparent, finely textured skin and a tendency to cold moist extremities. Migraine in its atypical forms is so readily forgotten that these patients are often unjustifiably delegated to that large and hopeless group called "neuroses." Migraine involving the heart has been described (Thomas, W. A., and Post, W. E.: *Paroxysmal Tachycardia in Migraine*, *THE JOURNAL*, Feb. 21, 1935, p. 569) as being closely associated with paroxysmal tachycardia. This association is quite common. Abdominal equivalents of migraine (Blitzstein, N. L., and Brams, W. A.: *Migraine with Abdominal Equivalent*, *THE JOURNAL*, March 6, 1926, p. 675, are frequent.

The intrinsic stability or instability of the vasomotor mechanism can be studied by means of the now well known and most significant cold pressure test of Hines and Brown (*Ann. Int. Med.* 7:289 [Aug.] 1933). This should be carried out with the patient. From the query one gains the impression that these attacks are not anginoid, but if the patient suspects that they may be evidence of dread "heart disease" it will take a deal of convincing to alter his way of thinking and diminish the fear engendered by these attacks.

#### PELOUZE TREATMENT FOR GONORRHEA

To the Editor:—In a recent issue of *THE JOURNAL*, mention is made of the Pelouze treatment for gonorrhea. Will you please briefly state an outline for this treatment, as I am unable to find it in any textbook that I have.

M.D., Nebraska.

ANSWER.—The treatment in question puts forth no claims of newness but is in reality an arrangement of well tried methods with their traumatizing possibilities deleted. It is based on several facts that should be uppermost in the minds of those who treat gonorrhea: The patient cures himself by his own tissue reactions and not solely because some type of treatment kills a few gonococci. Treatment to the infected tissue stimulates these curative processes. Alcohol, sexual excitement and often prolonged physical exertion put these responses in abeyance and prevent cure as long as they are indulged in. Thus the most important consideration of all is the gaining and holding of patient cooperation. Without it no treatment is efficient.

In his book (*Gonorrhea in the Male and Female*, Philadelphia, W. B. Saunders Company) Pelouze discusses all these things at length, as well as many other basic factors at play in gonococcal infections. Briefly stated, the treatment is as follows: For anterior urethritis, the earlier local treatment is instituted the more often is posterior urethral infection prevented. He has the patient empty his bladder in two glasses and records the appearance of both glasses. The anterior urethra is then gently irrigated with 1:8,000 potassium permanganate solution. After this, not more than 6 cc. of 5 per cent solution of mild protein silver is placed in the anterior urethra by means of an Asepto syringe and held there by a penis clamp for five or ten minutes. After this is allowed to drain, a piece of absorbent cotton measuring 2 by 6 inches is held over the glans by two no. 10 rubber bands, which the patient is instructed to leave off of the penis after the second urination so as not to interfere with drainage.

This treatment is carried out daily until there is no urethral discharge between treatments and the first glass of voided urine contains only shreds (usually two weeks). The intervals between treatments then are spaced at forty-eight hours and later seventy-two hours, depending on whether or not a discharge appears before the time is up. The patient does nothing but behave himself and appear for treatment. He eats and drinks what he pleases so long as there is no alcohol in it. The utmost care is taken to prevent any of the treatment solutions from passing into the posterior urethra. From 75 to 85 per cent of the cooperative patients seen before the fifth day fail to have a posterior extension of disease. Of those who do not, 90 per cent are well by the end of six weeks and 10 per cent take from one to three weeks longer.

For posterior urethritis, in acute posterior urethral infection oral sedatives are given and all local treatment, except hot hip baths, is stopped until about a week after the patient has regained his bladder comfort. Then low pressure (not more than 3 feet) hydrostatic irrigations of 1:8,000 potassium permanganate are given into the bladder (no catheters or other urethral instruments are ever passed until it is safe to assume the gonococcus no longer is present). The bladder is only partially filled, the patient voids and this is repeated several times, some of the solution being left in the bladder at the end of the treatment. Treatments of this type are carried out two or three times a week.

When there has been no obvious urethral discharge for several weeks, the second glass of urine is crystalline and the first contains but a few shreds, the very gentlest type of prostatic stroking is tried. If this causes a marked recurrence of urethral discharge, it is not tried again for two weeks. If, as is usually the case, it caused but the slightest urethral discharge next day or none at all, the treatments are continued twice a week. The bladder is irrigated, some fluid is left in, the prostate is stroked and the patient voids some of the solution. Gradually the pressure on the prostate is increased at future treatments but never to the point of acute pain.

From this point on the twice a week treatments are continued until the prostatic secretion is free from pus. To avoid the

**Mansions in the Cascades.** By Anne Shannon Monroe and Elizabeth Lambert Wood (in collaboration). Cloth. Price, \$2.50. Pp. 325. New York: Macmillan Company, 1936.

To the lover of the great open spaces, the seeker after adventure with a spice of danger, this book will come as a clean wind off a glacier, calling him to come and live under the sky, where the mountains hem him round in solemn majesty. The story is not a new one; a man, who happens to be a doctor—though anybody else would have done for the purposes of the story except in one situation—breaks under the stress of adversity and seeks solitude as wild creatures mortally wounded crawl away to die. His wife, against his will, goes along. They have camped in the mountains before but have never wintered there. Now they do, and that is the story. How health returns and with it tranquillity of mind is developed logically and plausibly; the reader is not asked to believe any miracles. How the wilderness brings them as well some comfort for the loss of their children makes a charming additional interest. The reader feels that these authors have either lived some of this story themselves or been exceedingly close to it; certainly they give clear evidence of having known intimately and loved the country that is the locale of the story. The book, though it deals with a physician who heals himself with the aid of nature, has no special significance for doctors, but it is fine reading for anybody.

**A Practical Medical Dictionary of Words Used in Medicine with Their Derivation and Pronunciation Including Dental, Veterinary, Chemical, Botanical, Electrical, Life Insurance and Other Special Terms; Anatomical Tables of the Titles in General Use, the Terms Sanctioned by the Basle Anatomical Convention; Pharmaceutical Preparations Official in the U. S. and British Pharmacopœias or Contained in the National Formulary, and Comprehensive Lists of Synonyms.** By Thomas Lathrop Stedman, A.M., M.D. Thirteenth edition, with the New British Anatomical Nomenclature. Fabrikoid. Price, with thumb index, \$7.50; without index, \$7. Pp. 1,291, with illustrations. Baltimore: William Wood & Company, 1936.

This volume, first offered to the public in 1911, is now in its twenty-fifth year. Its success is obvious. The new edition takes account of changes in the Pharmacopœia as to definition and spelling and attempts also to lead medical users into a gradual reformation in spelling. The editor indicates in his preface the difficulties that he himself is having with anatomic terms. This dictionary, unlike others, begins with a section devoted to medical etymology, which is planned to show users the manner of origin of most of the terms used in medical science. The dictionary is nicely illustrated with excellent plates. It is supplemented by numerous tables, giving a great deal of concentrated information, and is altogether one of the most useful medical dictionaries that are published.

**Practical Physiological Chemistry for Medical Students.** By G. M. Wishart, D. P. Cuthbertson and J. W. Chambers. Paper. Price, 3s. 6d. Pp. 127. Glasgow: John Smith & Son, Limited, 1936.

This is a conservative laboratory manual, including simple experiments in physical chemistry, quantitative tests of the elements in the body, and simple experiments on proteins, fats and carbohydrates, lipids, foods, digestion, blood and urine. The book is modernized to the extent that the chemical balance is not used but, on the other hand, no use is made of a colorimeter, although an attempt is made to perform quantitative colorimetric comparisons in a test tube. This limits the use of quantitative micromethods to sugar, hemoglobin and urea on blood. Some quantitative work is done on the urine. Although the book contains few errors, some statements might mislead a student. Thus the xanthoproteic reaction is mentioned in connection with phenylalanine, whereas this reaction is so slow on phenylalanine that it is usually considered negative. The only quantitative determination of protein is the Sørensen titration for amino nitrogen in milk. The number of cubic centimeters of tenth normal sodium hydroxide is multiplied by 0.17 to give the grams of protein. In the examination of gastric contents, the acidity is determined. The titration with tenth normal sodium hydroxide, Töpfer's reagent being used, to a salmon pink is recorded as the free hydrochloric acid. Then phenolphthalein is added, and the titration to phenolphthalein is called the total acidity and is attributed to the free hydrochloric acid, acid salts, and acid in combination with protein. Then a total chloride is determined by Volhard's method for urine, which involves the removal of protein. It is probable that such removal would remove the acid in combination with the protein, and since this was shown long ago by Prout

to be hydrochloric acid, this would cause an error in the chloride determination. Apparently no use is made of the total chloride determination. Since the book is printed only on one side of the paper, space is provided for the writing in of the micromethods on blood that are necessary in hospitals.

**A Textbook of Surgery.** By John Homans, M.D., Clinical Professor of Surgery, Harvard Medical School. Compiled from Lectures and Other Writings of Members of The Surgical Department of The Harvard Medical School. With a special bibliographical index and with 530 illustrations by Willard C. Shepard. Fourth edition. Cloth. Price, \$8. Pp. 1,267. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1936.

The success of this volume is represented by four editions in five successive years. The present edition includes new chapters on amputation and plastic surgery, particularly with a view to meeting the demands of examining boards. The old type having become worn, the new volume is completely revised and reset. The author admits frankly that little additional new material has been added.

**Le métabolisme de l'azote. Physiologie des substances protéiques. 1. Aliments, digestion, absorption, enzymes digestifs.** Par Emile F. Terroine, professeur à l'Université de Strasbourg. Les problèmes biologiques. Collection de monographies publiées sous le patronage du Comité technique des sciences naturelles des Presses Universitaires de France, XX. Paper. Price, 80 francs. Pp. 384. Paris. Les Presses Universitaires de France, 1936.

In this volume a well known authority on the subject presents an exhaustive account of what happens to the protein foodstuffs from the time they are ingested to the absorption of their end products into the blood stream. The book is divided into four main parts: 1. Protein foodstuffs and their digestion. 2. The nature of the absorbed products. 3. The sequence of events in digestion and absorption. 4. The digestive enzymes: their respective rôles, and the conditions influencing their activity. As in his previous works on other aspects of protein metabolism, the author presents his material in a precise and systematic manner. The subject matter is divided into short sections and paragraphs, each of which bears a subheading indicating its content. The text is liberally illustrated by tabular data, and the extensive bibliography is international in character. Its encyclopedic detail renders this volume more suitable as a reference work than as a textbook for medical students or physicians. But it should be a valuable addition to the library of any one who is particularly concerned with the physiology of the gastro-intestinal tract.

**Modern Treatment and Formulary.** By Edward A. Mullen, P.D., M.D., F.A.C.S., Assistant Professor Pharmacology and Physiology, Philadelphia College of Pharmacy and Science. Foreword by Horatio C. Wood Jr., Professor of Therapeutics in University of Pennsylvania, Graduate School of Medicine. Fabrikoid. Price, \$5. Pp. 707. Philadelphia: F. A. Davis Company, 1936.

This is a physician's office desk reference book that is full of practical information on questions of treatment. Indeed, it aims to be so all inclusive as to include a summary on differential diagnosis, and on the treatment of surgical emergencies and of poisoning. There is also included the physician's "interpreter" in five languages intended to help the physician to formulate questions in French, German, Italian and Spanish that may yield affirmative or negative answers of diagnostic importance. It is in many ways an excellent book and as criticism there needs be—such is expected in any review—one might say that some of the prescriptions suffer from a redundancy of ingredients and some from a lack of attention to elegance and palatability.

**Preparation for Marriage.** By Ernest R. Groves. Cloth. Price, \$1.50. Pp. 124. New York: Greenberg, 1936.

The author makes a plea for open discussion of problems of a real nature before marriage and their solution at that period rather than after marriage. Common sense attitudes toward the question of health, heredity, finances, housing and children are expressed. The common sense attitude written in cold print gives the appearance of old platitudes and is as readily ignored as all platitudes in the midst of the emotional stresses attendant with falling in love. Rarely is one of the author's strictures followed by the people most concerned, and certainly the person in love will not stop to read this book. Being without insight into the real needs of adequate handling of the sex problems which the curious child attempts to solve early in life, the book is of limited use.

Kouwenhoven observes that heavy currents cause heart stoppage while low current densities in the body cause fibrillation of the heart, and that such fibrillation seldom disappears automatically. However, running through this persistent situation there is likely to be a neurotic component which possibly should be duly evaluated.

The nature of cardiovascular injuries following electric shock is worthy of a much more extended discussion than space here permits. Reference is therefore made to the following publications:

Langworthy, O. R., and Kouwenhoven, W. B.: Importance of the Points of Contact in Electric Injuries, *J. Indust. Hyg.* 13: 145 (May) 1931.

Langworthy, O. R., and Kouwenhoven, W. B.: Injuries Produced in the Organism by the Discharge from an Impulse Generator, *J. Indust. Hyg.* 13: 326 (Nov.) 1931.

Jellinek, Stefan: The Pathology of Electric Current Burns, *Wien. klin. Wchschr.* 34: 239 (May 19) 1921.

Urquhart, R. W.: Experimental Electric Shock, *J. Indust. Hyg.* 9: 140 (April) 1927.

Haberlandt, L.: Heart Fibrillation and Electric Current, *Wien. klin. Wchschr.* 39: 774 (July 1) 1926.

These articles in some instances discuss the emergency treatment of electrically produced cardiac lesions. However, after an interval of eighteen months much of such treatment is not applicable. For general treatment, reference is made to a recent publication by George R. Herrmann (Synopsis of Diseases of the Heart and Arteries, St. Louis, C. V. Mosby Company, 1936).

#### GYNECOMASTIA

To the Editor:—What is the approved treatment of gynecomastia? A boy of 18 is normal physically except for symmetrical enlargement of both breasts. There is considerable increase in the fatty tissue and a very prominent areola and nipple, which become erect on the least stimulation. The genitals are fully developed and the distribution of pubic hair is normal. The previous history is negative except that the patient's mother says the breasts were large several months after birth. The unusual growth began, or was first noticed, eight months ago. What tests would you suggest to confirm the diagnosis and what treatment would be advisable?

W. M. ELLIOTT, M.D., Forest City, N. C.

To the Editor:—May 28, 1936, a youth aged 21 years, of normal height and weight, presented himself at my office complaining of painful and cumbersome breasts. He noticed particularly in the last year that slight trauma of either breast, more particularly the right breast, caused marked pain. This condition has been present for three or four years but the breasts have been larger in the last year. There has never been any secretion of any kind from them nor has there been any acute localized inflammation leading to mass or pus formation in either of them. The patient appears normal, healthy and vigorous, is 5 feet 10½ inches (178 cm.) tall and weighs 170 pounds (77 Kg.). The blood pressure, Wassermann reaction, hemoglobin and differential count are all within normal limits. Fluoroscopic examination, urinalysis and basal metabolic tests give negative results. There is a soft fuzz on the lip and the chin, requiring one shave a week, and the skin texture of the face is smooth. The breasts are the size and shape of the breasts of a girl 16 years of age. The pubic hair is of triangular distribution. The testicles are small and the genitalia within normal limits. The patient states that he has normal sexual impulse and relations. Any information that you may offer as to diagnosis and treatment will be greatly appreciated; also any comment as to danger of malignancy in this type of breast tissue and also prognosis concerning the ultimate outcome. Please omit name.

M.D., New York.

ANSWER.—These descriptions cover the typical picture of gynecomastia. In the diagnosis of enlargements of the male breast one must consider (1) true tumors (fibromas, fibrosarcomas, very rarely carcinomas), (2) gynecomastia, which is true hypertrophy of the glandular tissue, and (3) the so-called spurious gynecomastia, which is an increase in the fatty and fibrous tissues. The description of the breasts in the second case as being "of the size and shape of the breasts of a girl 16 years of age" corresponds to the typical appearance in true gynecomastia of the puberty type. Gynecomastia has been observed in relation to atrophy and tumors of the testicles, especially tumors of the chorionepitheliomatous group, and furthermore to tumors of the adrenal body and of the hypophysis. In recent years also a relationship to hepatic cirrhosis has been reported in several instances. All these conditions are extremely rare, and in most instances the cases belong to the group of essential gynecomastia which occurs during puberty and is mostly found in otherwise normal young men. It may be due to some endocrine disturbance of a more complicated nature. Certainly the hypofunction of the testicle alone is not responsible. In most instances the testicular function is normal.

As to the treatment, the results of etiologic treatment are not yet available. It may be that the application of the active preparations of the male hormone, which have been on the market only for a short time, may be of some value, although this is questionable. Most cases do not require treatment,

since the condition is harmless. The danger of malignant degeneration is extremely slight, although there are some rare instances on record which later on became carcinomatous. Some of these conditions, however, may have been tumorous conditions from the beginning and not true gynecomastia.

Recently Menville has recommended a trial with roentgen irradiation in active gynecomastia, although he has found it ineffective in the chronic forms (*Arch. Surg.* 26:1054 [June] 1933). When the patient insists on removal, plastic surgery may be used with good results.

#### DIGITALIS AND VACCINES IN RHEUMATIC FEVER

To the Editor:—A white man, aged 30, single, weighing 180 pounds (82 Kg.), height 5 feet 10 inches (178 cm.), had one attack of acute rheumatic fever about six years ago. For the past three weeks he has been confined to bed with an acute exacerbation of rheumatic fever with typical symptoms. The temperature ranges from 100.2 to 103.4 F. There are drenching sweats. He has a loud blowing systolic murmur at the apex, transmitted to the axilla. Recently he developed pleurisy in the left side and now he has developed a pericarditis. The pulse ranges from 72 to 90. When I first saw him three weeks ago he started off with acute catarrhal jaundice. That cleared up and as it did so he had migrating pains in both knees, the shoulders, the fingers and the sternum. Treatment has been: (1) rest in bed; (2) 15 grains (1 Gm.) of enteric coated sodium salicylate and 30 Gm. of sodium bicarbonate by mouth every two hours; (3) cascara 5 grains (0.3 Gm.) at night for the bowels; (4) codeine sulfate one-fourth grain (0.016 Gm.) by the peroral method for the pain as often as necessary; (5) phenobarbital one-fourth grain as often as necessary for restlessness; (6) 1 cc. hypodermically of Sherman 35 vaccine for the last ten days. As yet I have not used digitalis because most of the time his pulse has remained around 78. Recently I strapped the left chest for pleurisy. Kindly advise whether I should use digitalis or not because of the previous history and the heart murmur. Also, advise whether I should discontinue the Sherman 35 vaccine or not. Is it of any value? His teeth are apparently sound but I should like him to get them roentgenographed later. His tonsils are definitely diseased, and I have told him they should come out after he is over this sickness. Would you recommend having the tonsils removed now? The patient lives out in the country and has no desire to be moved now to a hospital. He states that he prefers to diet at home. Please omit name.

M.D., New Jersey.

ANSWER.—Digitalis is not indicated. The only reason for using digitalis would be to control an auricular fibrillation, which is not present. Digitalis could not influence either the murmur or the rheumatic fever. It is doubtful whether the sodium salicylate has any value except as an analgesic. The bowels are best controlled without medication as far as possible. The daily use of cascara will probably result in an overstimulated colon and a constipation of a spastic type. Vaccines probably have no therapeutic value in any condition, and certainly none has been shown in rheumatic fever. The only therapeutic measures of known value are absolute rest in bed, and time. He should not be allowed up until the pulse and temperature have been normal for at least two weeks and until the sedimentation rate has returned to normal.

If the tonsils are definitely diseased after recovery, they had best be removed.

The possibility that the jaundice was due to absorption of some hemorrhagic infiltration of the lungs must be considered, or that it was in some other way concerned with the primary condition.

#### THE PASTE METHOD FOR SCRATCH TESTS

To the Editor:—1. Is the paste method, containing multiple substances, a dependable one for scratch testing? The paste consists of the dry substances mixed in 50 per cent glycerin. 2. Is the paste method, containing single allergens, a dependable and accurate one for skin testing by the scratch method? Please omit name.

M.D., Ohio.

ANSWER.—1. While the paste method is reliable for testing cases with a high degree of sensitivity by means of scratch tests, the allergens embodied in the paste are in general less active than in powder form or in solution. Lower degrees of skin hypersensitivity may therefore be missed when the paste is used. When the paste contains multiple substances, each single allergen is of course present in proportional dilution and is therefore weaker in effect than when single allergen pastes are used.

2. For this reason, the single allergen paste is usually superior to the one with multiple substances. In general, when the scratch method is employed for testing, it is more dependable and accurate to use either the dry powders or the glycerin extracts of allergens. An important consideration is that the physician get to know whatever allergens are being employed so as to recognize those small wheals and erythema which are not due to specific hypersensitivity but to the irritant effects of certain allergenic substances.

of the patient twenty years ago could have been of this nature. If records exist they might furnish helpful information. However, instead of the skull being the chief seat of the disease, as in the Hand-Schüller-Christian syndrome, the lesions are more frequent in the diaphyses of the long bones. The fibrous healing stage that occurs in the lipid granulomas provokes an osteoplastic reaction, with new formation of bony substance. It may be these lesions which account for the rheumatoid symptoms of the patient and give the x-ray appearance which has been ascribed to sodium urate infiltrations. It is possible, of course, that cholesterol metabolism is governed by some endocrine secretion, as suggested, but we are unaware of any evidence that such is the case. The treatment of these conditions is largely symptomatic.

If this case should turn out to be an essential xanthomatosis, the occurrence of an increased blood uric acid content may depend on an extensive involvement of the liver by the lipid granulomatosis. Other evidences of liver dysfunction might be confirmatory in this regard.

#### PULMONARY EMBOLISM

*To the Editor:*—August 14 I was called to see a man, aged 34, apparently suffering from a pulmonary embolism. About a week before he had had some varicose veins in the left calf injected in four places with sodium morrhuate. Although he was suffering some discomfort, he kept up and active. When first seen he was suffering excruciating pain over the heart and upper part of the chest was dyspneic. The following day he exhibited some moist râles in the base of the left lung, which cleared in twenty-four hours and were replaced by râles in the upper part of the left chest. On the third day he developed a definite pleuritic rub in the left axilla, with pain which cleared in forty-eight hours. Since then the chest signs have all cleared. He has not been roentgenographed, owing to difficulty in negotiating narrow stairs. Should he now be treated as for an ordinary thrombophlebitis and confined to bed from four to six weeks? All tenderness of the veins in the leg has gone. How long would any x-ray signs show from a small pulmonary embolism? Please omit name.

M.D., New York.

*ANSWER:*—The diagnosis of pulmonary embolism is well founded on the basis of the submitted data. Such a patient must be kept in bed for about ten days after the pulse and temperature have returned to normal. A more accurate index is the sedimentation rate, which can be determined several times and which should be normal before the patient is allowed to get up. Small pulmonary emboli need not give any x-ray changes. Large, triangular infarcts are absorbed slowly; if the infarct occurred at the base of the lung, the diaphragmatic pleura may become involved and result in an uneven contour of the dome of the diaphragm, which may persist for years.

#### SCLEROSING SUBSTANCES IN HYDROCELE

*To the Editor:*—What sclerosing injections, if any, are now favored in the treatment of hydrocele of the type in which more caustic ones were used years ago?

W. K. KEITH, M.D., Creston, Iowa.

*ANSWER:*—A hydrocele, unless it simply masks a tuberculous or gonorrheal epididymitis, a syphilitic orchitis or a tumor of the testicle, may be injected with substances that denude the endothelial lining of the sac, produce a fibrinous exudate and result in obliteration. Sodium morrhuate in 10 per cent solution has been used recently for such obliterating injections, which may have to be repeated several times at weekly intervals. If care is exercised not to inject any sac that communicates with the peritoneal cavity, the procedure is harmless and can be carried out on ambulatory patients. In well trained surgical hands, the operative treatment of hydrocele is equally harmless. No comparable data exist with regard to end results, but the hydroceles with thickened sacs respond less favorably to the injection treatments. The so-called bottle-neck operation offers excellent results.

#### CHRONIC STREPTOCOCCIC INFECTION OF LEG

*To the Editor:*—A white man, aged 23, stuck a blunt, wooden object into the calf of his leg three years ago. The wound was very slow in healing. From his history I believe it was an infected wound. Now he comes to me two or three times a year with a reddened area on the calf of his leg and a definite lymphangitis. The temperature ranges from 102 to 103. Can you give me any suggestion of how I can eliminate this chronic streptococcic infection? E. W. BECKES, M.D., Vincennes, Ind.

*ANSWER:*—With a definite history of having been struck by a wooden object over the site of the inflamed area, it is quite probable that a portion was broken off and is still in the tissues. A roentgenogram should be taken of the entire leg. This will rule out osteomyelitis. It may also show a wooden splinter if there is a little lead paint on it; otherwise the

roentgenogram may be completely negative or show a slight tissue thickening around a chronic pyogenic abscess of the soft parts.

If the inflammation is limited to the skin, it may be a recurring erysipelas, in which event immunization may be attempted from a toxin obtained from cultures from the leg or from stock streptococci.

Precautions should be used against irritation or from external infection and the general system should be built up by means of an improved diet and change of habits or medication as indicated.

#### TREATMENT OF TUBERCULOUS CERVICAL GLANDS

*To the Editor:*—What is the latest treatment of cervical tuberculous glands? Is there any accepted new procedure over mere excision or drainage?

DAVID KRAMER, M.D., Silver City, N. M.

*ANSWER:*—The elimination of the source of the infection should always be the first consideration. There is no new or specific treatment. Systemic treatment should be given to build up general resistance by attention to rest, habits, food and medication as indicated. Ultraviolet ray exposure is of value particularly when it is impossible to obtain adequate sunshine, although it has little local specific reaction. If the glands are broken down with sinuses, roentgen treatment is of value. If the glands are hyperplastic and discrete in type, surgical excision is indicated if they do not subside after a reasonable period of medical treatment.

#### DRYNESS OF MOUTH IN CARCINOMA

*To the Editor:*—A woman who has an inoperable carcinoma of the breast with metastasis to the liver complains bitterly of dryness of the mouth and tongue. The oral mucous membranes are excessively dry, but there is no general dehydration and the fluid intake is adequate. All kinds of local measures, such as the use of various mouth washes, the chewing of gum and paraffin, and the sucking of sour lozenges, have been tried. No relief has been obtained. Have you any further suggestions? Please omit name.

M.D., Ohio.

*ANSWER:*—A trial may be given with the peroral application of pilocarpine in 1 per cent solution, from 3 or 5 to 8 drops daily. Sometimes salivation is increased in this way. The individual sensitivity to pilocarpine varies widely, and therefore a trial must be made to determine the adequate dose in the particular case.

#### OPTOMETRIC COLOR CHOICES

*To the Editor:*—The optometrists in the state of Arkansas are advocating changing of the roadside markers, the chalk in schools and the pavement stripes to orange-yellow. Fearing that this is a scheme to gain newspaper publicity and propaganda, before condemning it I would appreciate hearing from you as to your opinion of the value to visual acuity, the lack of eyestrain, and so on, provided these changes are made. It would seem that they are trying to get up enough publicity about this and the contact lens in order to bring their society more into the limelight as benefactors to mankind. I would appreciate it if you would let me hear from you at your earliest convenience, and if you print this letter please omit name. Thank you.

M.D., Arkansas.

*ANSWER:*—It does not make one particle of difference from the standpoint of visual acuity or eyestrain whether white or orange-yellow is used for the purposes described. The endeavor to change the color is what Barnum would call a "come on" and is of infinitely more value for optometric publicity than for public eye benefit.

#### DIPHTHEROID ORGANISMS IN EAR INFECTION

*To the Editor:*—I have a patient with an ear infection of pure *Bacillus pseudodiphthericus* with sympathetic nasal phenomena aggravated at the menstrual period. It has been slow to yield to either mercurial antiseptic or salicylic acid in alcohol. Will you kindly advise further procedure? Please omit name.

M.D., California.

*ANSWER:*—Diphtheroid organisms in a discharge from the middle ear usually are the result of secondary infection in chronic otitis media. The correspondent does not state whether this is an acute or a chronic otitis media. If it is the latter with a central perforation, "dry" treatment is usually effective, consisting of drying out the canal and middle ear with cotton applicators followed by boric acid powder blown in, and repeated every few days until the discharge ceases. If there is a marginal type of perforation with cholesteatoma, the epithelial debris must be washed out with an attic cannula by means of warm 70 per cent alcohol unless the cholesteatoma cavity should be too extensive to be rendered dry and inactive by this treatment, in which case a radical mastoid operation may be indicated.

## Book Notices

**Comparative Anatomy.** By Herbert V. Neal, Professor of Zoology, Tufts College, and Herbert W. Rand, Associate Professor of Zoology, Harvard University. Cloth. Price, \$1.75. Pp. 739, with 540 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

An alternative title to this book might well be *The Evolution of Man and Other Animals*. The introduction constitutes one of the best brief statements of the theory of evolution that has appeared. It includes a consideration of "creative synthesis" as the foundation of "emergent evolution." Matter in passing from one plane of organization to another passes also from one set of properties to another, from "nonliving" to "living" to "conscious living" to "ethical living." This statement does not include the causes of evolution, and no attempt is made to convey the impression that evolutionary change and progress can be adequately explained at present. The scope of the book includes not only comparative anatomy of adult forms but also the ontogeny and phylogeny of animals; it includes not only gross anatomy but also minute anatomy and the evolution of the tissues. The method of treatment is not by classes of animals, as in so many books on the subject, but by systems and organs—integumentary system, skeletal system, and so on. Successive chapters deal with the integumentary system, teeth, the skeletal system, the muscular system, the digestive system, the respiratory system, the vascular system, the urogenital system, the endocrine organs, the nervous system, and the sense organs. In each chapter the evolutionary history is followed, and the book is a picture of evolution at work. The anatomy of various animals furnishes simply the illustrative parts of the picture. Inevitably this plan leads to a last chapter on the ancestry of the vertebrates. Figure 1 is a tentative family tree of the animal kingdom; figure 540, the last in the book, is a duplicate of it. Figure 26 is a tentative family tree of the primates. The ancestral line is not definitely and finally drawn—maybe it never will be. It appears that the separation of phyla occurred further back than has usually been assumed. It is suggested that the vertebrate line split off below the flatworms and below the coelenterates. The annelid worms are close to our ancestral line. It is suggested that future students of phylogenesis will turn more to comparative embryology than they have done in the past. The book is a valuable and welcome addition to the literature on this subject. It presents the hypotheses or propositions advanced by the best minds thinking in the field and illustrates them by examples. The presentation is clear and the idea is "not buried under a blizzard of facts." Students will find it a source of knowledge and of understanding. In the light thrown by this book on the facts of comparative anatomy, they glow with significance and interest.

**The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects.** Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. Volume I: Abdominal Pain to Appendicitis. Cloth. Price, \$12. Pp. 742, with 96 illustrations. London: Butterworth & Co., Ltd., 1936.

Hardly is one new system of medicine completed before another comes upon the scene. The British publishers now offer a system of medicine, indexed alphabetically, with a view to covering every branch of medical practice. Each of the subjects is handled by a British writer of repute in the field concerned, and each chapter when completed is passed under the supervision of the general editor and his associates. It is planned to publish a supplement each year in order to keep this system up to date. The prospectus issued with the first volume may be had directly from the publishers and indicates the subjects discussed and the number of authors included.

The volume is especially interesting as a beautiful production typographically. The first volume contains ninety-six pictures. The type is easily readable, beautifully spaced and sufficiently varied to indicate the importance of various subdivisions. Moreover, there is marginal indexing, which aids ready reference.

The American reader will of course have some difficulty because of the references to the British pharmacopeia rather than the American.

The authors are not averse to expressing themselves frequently concerning their experience with various methods of treatment. For example, this statement under the use of

manganese and vaccines in acne: "Injections of manganese and of vaccines appear to be of very little value in acne. The same may be said of purgation by salts and the swallowing of yeast or preparations of tin." It is interesting to observe that the section on actinomycosis provides but few references to the extensive American contributions made on this topic. The section on actinotherapy is more optimistic than the scientific observations made in this country seem to warrant. The editors have undoubtedly concerned themselves greatly with the condensation of the material, so that altogether the information here available is concentrated so as to be free from diffuse and unnecessary diction.

Each of the volumes is separately indexed, and an exhaustive analytical index is to be published in a separate volume when the entire series is completed.

**Roentgen Interpretation: A Manual for Students and Practitioners.** By George W. Holmes, M.D., Roentgenologist to the Massachusetts General Hospital, and Howard E. Ruggles, M.D., Roentgenologist to the University of California Hospital. Fifth edition. Cloth. Price, \$5. Pp. 356, with 243 illustrations. Philadelphia: Lea & Febiger, 1936.

The fact that this manual could attain its fifth edition gives sufficient evidence of its value. It is a standard work of American x-ray literature. Written for students and practitioners, the volume is nevertheless of interest for the specialist too, because it is founded on the basis of the authors' wide experience and is not merely compiled from the bibliography. Hence the book gives the vivid impression of a personal, clinical study and not that of a laboratory guide. The language is short and clear. The illustrations, except for a few reprinted from former editions, are excellent. The short remarks about the clinical values of roentgenologic examinations, whether positive or negative, are valuable. The chapter concerning the spine is particularly good. A few remarks may be too subjective for a student's manual. One cannot agree that "triangular areas of filmy density are the earliest evidence" of a tuberculous involvement of the lungs. The opinion that scalloped contours of any involvements of the bones are characteristic of tuberculosis will not be shared by all roentgenologists. But such insignificant objections could be refuted by the authors if they would increase the extent of their manual to a complete textbook, and that is what we recommend for the next edition, in view of the impressive clinical knowledge of the authors.

**Radiothérapie gynécologique: Curié et roentgenthérapie.** Par R. Mathy-Cornat, radiologiste des hôpitaux. Paper. Price, 60 francs. Pp. 369, with 81 illustrations. Paris: Masson & Cie, 1936.

This book, written by the radiologist of the Centre anticancéreux in Bordeaux, offers in a brief form to those who read French a convenient and comprehensive source of information regarding the present indications, accomplishments and limitations in the application of radiation therapy in the different diseases of the female genital organs and the breast. A brief chapter on the physics and biology of gynecologic radiotherapy, with a consideration of the clinically important facts, is followed by a discussion of the radiation treatment of benign lesions of the female genital organs, including functional disturbances, indications and methods of radiation sterilization, and inflammatory conditions of the female genital organs. The largest part deals with the treatment of malignant tumors and a final chapter with radiation treatment of cancer of the breast. The book is completely brought down to date. In some places it might even appear too modern, as it discusses methods that have not yet quite proved their value. In its general tenor the book is based on the leading ideas of the French school. The best parts are those founded on the author's own experience and the experience of the Paris school. The choice of the discussion of other methods and results seems somewhat arbitrary. Besides the value of this book as a brief textbook giving a critical and objective survey of the entire field, its chief value consists particularly in the excellent discussion of radiation therapy of uterine cancer. With these parts one can agree in every detail. The comprehensive and convenient compilation of the scattered material concerning the results of radiation therapy in cancer of the cervix in fair comparison to the surgical results might help to advance the knowledge of the true facts regarding the accomplishments of radiotherapy in uterine cancer, which are often not yet well enough known and appreciated. An extensive bibliography is appended.
